This study included 101 T2DM patients with MASLD. Neither the presence of metabolic syndrome nor its individual components (waist circumference, dyslipidemia, systolic blood pressure, diastolic blood pressure) were significantly associated with the risk of fibrosis in our cohort (FIB-4: $P = 0{,}068$; NFS: $P = 0{,}232$). The most notable association was with hypertension, which was significantly linked to fibrotic liver lesions based on the NFS score ($P = 0{,}033$). Regardless of the fibrosis score used, spironolactone prescriptions were significantly more frequent in patients at high risk of advanced fibrosis (FIB-4 : $P = 0.031$; NFS : $P = 0.006$). Other antihypertensive treatments (renin-angiotensin system blockers, calcium channel blockers, thiazide diuretics, and beta-blockers), as well as their adherence, had no significant impact on the progression to advanced fibrosis. Additionally, no substantial effect on advanced fibrosis was observed from any dyslipidemia parameters or lipid fractions in the included patients.
Conclusion
This study aims to shed light on key cardio metabolic risk factors contributing to fibrosis progression, ultimately informing targeted interventions.

Prevalence of metabolic dysfunction-associated steatotic liver disease in patients with type 2 diabetes mellitus: a tunisian study

Yesmine Elloumi[1], Mouna Elleuch[1], Khouloud Boujelben[1], Yasmine Abdelkafi[2], Faten Hadj Kacem[2], Nadia Charfi[2], Mouna Mnif[3], Dhoha Ben Salah[2] & Nabila Rekik Majdoub[2]
[1]Hedi Chaker University Hospital, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia; [3]Hedi Chaker Univeristy Hospital, Sfax, Tunisia

Background
Metabolic Associated Steatotic Liver Disease (MASLD) is a growing global health concern. The coexistence of MASLD and Type 2 Diabetes Mellitus (T2DM) poses a significant clinical challenge, as both conditions are intertwined through common pathophysiological mechanisms. Understanding the prevalence of MASLD in T2DM patients is crucial for developing effective screening, prevention, and treatment strategies. This study aims to investigate the prevalence of MASLD in T2DM patients.
Methods
This was a retrospective study that included patients followed for T2DM from 2012 to 2024 at the Endocrinology and Diabetology Department of the Hedi Chaker University Hospital in Sfax, Tunisia. The diagnosis of MASLD within T2DM patients was based on the 2024 EASL-EASD-EASO guidelines on the Management of MASLD.
Results
A total of 734 patients with T2DM was recruted and underwent abdominal imaging. 609 patients (83%) had normal imaging results, while 125 patients (17.03%) were diagnosed with hepatic steatosis. Thus, the prevalence of MASLD in our cohort of T2DM patients was found to be 17.03%. The mean age of the diabetic patients with MASLD was 53.7 ($\pm$15.2) years, with a female predominance of 62.4%.
Conclusion
Our study provides valuable insights into the burden of this dual diagnosis emphasizing its clinical significance. These findings highlight the critical need for early detection and effective management of MASLD in diabetic patients.

Dietary impact on the risk of progression to hepatic fibrosis in patients with type 2 diabetes

Yesmine Elloumi[1], Mouna Elleuch[1], Nada Hassairi[1], Maryem Akacha[1], kouloud boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Metabolic Associated Steatotic Liver Disease (MASLD) is an emerging condition among individuals with Type 2 Diabetes Mellitus (T2DM). Diet plays a critical role in metabolic health, yet its precise effect on the risk of progression to fibrosis in MASLD remains underexplored understanding the dietary factors contributing to its progression toward fibrosis is becoming crucial. This study aims to evaluate the dietary impac on the risk of progression from MASLD to fibrosis in case of T2DM.
Methods
This analytical study included type 2 diabetic patients with confirmed MASLD, followed at the Endocrinology-Diabetology Department in Sfax university in Tunisia. The fibrosis-4 index (FIB-4) and the NAFLD fibrosis score (NFS) were used to evaluate the risk of advanced fibrosis among the patients. For each patient, we assessed macronutrient intake, including daily caloric intake in Kcal, as well as the percentage of daily intake from lipids, proteins, and carbohydrates. We also evaluated the intake of saturated fatty acids, monounsaturated fatty acids, and polyunsaturated fatty acids along with micronutrient intake, including fiber (g/day), iron (mg/day), calcium (mg/day), and cholesterol (mg/day).
Results
Our study was conducted on 202 T2DM patients with confirmed MASLD. Total energy intake was not associated with the progression MASLD to fibrosis, as assessed by the FIB-4 and NFS scores ($P = 0.223$ and $P = 0.163$, respectively). Similarly, macronutrient intake did not correlate with fibrosis progression based on the NFS score. However, when the FIB-4 score was applied, significant associations were observed, specifically in carbohydrate intake ($P = 0.003$), lipid intake ($P = 0.041$), and polyunsaturated fatty acids intake ($P = 0.008$). No significant differences were found in protein intake or consumption of saturated and monounsaturated fatty acids, regardless of the score used. Additionally, we found that individuals with advanced fibrotic risk for MASLD, according to the NFS score, had higher dietary iron intake ($P = 0.048$). In contrast, no significant differences were observed in the intake of calcium, fiber, or cholesterol.
Conclusion
Our study aims to provide insights into the role of diet in the progression of MASLD to fibrosis in T2DM patients, offering potential avenues for targeted nutritional strategies to prevent or slow this progression.

Influence of degenerative complications of diabetes on the occurrence of infections

Yesmine Elloumi[1], Wissal Abbes[1], Dhoha Ben Salah[1], Maryem Akacha[1], Khouloud Boujelben[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Infections in diabetic patients represent a significant clinical challenge, particularly in those with degenerative complications of diabetes. The potential role of these complications in increasing infection risk warrants further investigation. This study seeks to examine the association between degenerative complications and the occurrence of infections.
Methods
A retrospective study was conducted involving diabetic patients hospitalized in the Endocrinology Department over one year who had undergone an evaluation of diabetes-related complications within the previous six months.
Results
The study included 195 patients, comprising 91 men and 104 women, with 29% having type 1 diabetes and 71% having type 2 diabetes. A significant difference was observed between the two groups in the prevalence of infectious complications (37% in type 2 diabetes versus 15% in type 1 diabetes ; $P < 0.05$). The most common bacterial infections in this population were urinary tract infections ($n = 21$), which were more frequent in women ($P < 0.05$), soft tissue

infections ($n = 21$), with 40% involving the foot, and bronchopulmonary infections ($n = 12$). The frequency of urinary tract infections, septicemia, and bronchopulmonary infections was not influenced by the presence of degenerative complications. However, foot infections were more frequent in patients with lower limb arteriosclerosis obliterans and those with sensorimotor polyneuropathy.
Conclusion
We highlight that among the most common bacterial infections in hospitalized diabetic patients, only foot infections are more frequent in the presence of peripheral artery disease or sensorimotor neuropathy. This underscores the importance of hygiene precautions and proper foot care.

Cardiovascular risk in relation to Body Mass Index in patients with type 2 diabetes mellitus

Hadhemi Belhassen[1], Ramla Mizouri[1], Rym Ben Othman[1], Siwar Saoudi[1], Faten Mahjoub[1], Berriche Olfa[1], Nadia Ben Amor[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, A, Tunis, Tunisia

Introduction
Epidemiological and clinical studies in the general population have demonstrated that overweight and obesity increase the risk of developing chronic conditions and are associated with all-cause and cardiovascular (CV) morbidity and mortality, independently of gender, age, and ethnicity. The aim of this study was to demonstrate this correlation.
Methods
Descriptive cross-sectional study conducted over 4 months in department A of The National Institute of Nutrition of Tunis which included patients with type 2 diabetes mellitus.
Results
Sixty patients were included amongst whom 36 were women and 24 men. The characteristics of the patients were respectively: age: 56 ± 13 years, Body Mass Index: 28 ± 6 Kg/m^2. There was no statistically significant correlation between the Body mass index and coronary artery disease ($P = 0.6$), stroke nor transient ischemic attack ($P = 0.4$). However, obesity was a predictive factor for the development of lower extremity artery disease ($P = 0.001$).
Conclusions
The degree of obesity is an important factor that can aggravate the metabolic patients' profile, but its effect on cardiovascular risk is rather correlated to its association with the other risk factors.

Can we predict the onset or worsening of microangiopathies in pregnant women with diabetes mellitus during pregnancy?

Hadhemi Belhassen[1], Yosra Htira[1], Chaima Jemai[1], Laajili Olfa[1], Hedfi Imene[1], Haj Ali Zohra[1] & Feika Ben Mami[1]
[1]National Institute of Nutrition, C, Tunis, Tunisia

Introduction
Pregnancy is a major factor in the imbalance of diabetes, irrespective of its type. It favours the onset and/or worsening of microvascular complications such as diabetic retinopathy and nephropathy. Our study aims to highlight potential predisposing factors to these microangiopathies in diabetic pregnant women.
Methods
We conducted a descriptive retrospective study involving 100 known diabetic pregnant women in ward C of the National Institute of Nutrition.
Results
The mean age was 32.87 ± 5.3 years, with a predominance of multigestational women (54%) and nulliparous women (37%). Type 2 diabetes was present in 52% of parturients. The average duration of diabetes for all types was 7.57 ± 6.66 years. A minority (29%) had well-controlled diabetes on treatment, with an HbA1C < 7%. Non-proliferative diabetic retinopathy and diabetic nephropathy associated with at least one microalbuminuria complicated 6.1% and 4.8% of diabetics, respectively. No new onset or worsening of diabetic retinopathy was detected throughout the pregnancy. The same applies to the worsening of diabetic nephropathy and creatinine clearance. The only patient with macroalbuminuria decreased her proteinuria during pregnancy.
Conclusions
Glycaemic and blood pressure control are protective factors against microangiopathies during pregnancy, even in cases of previously complicated diabetes. Hence, the importance of pregnancy planning and monitoring during the gestational period.

Case of complete remission of diabetes mellitus type 1

Ana Matijaca[1]
[1]Clinical Hospital Dubrava, Zagreb, Croatia

A 27-year-old female was referred to the outpatient clinic due to symptoms of insulinopenia, unintentional weight loss, polyuria, and polydipsia. The patient was obese with an ITM of 31 kg/m^2 and had prior GDM during her first pregnancy three years ago with a burdened family history (her father has DM2). Fasting blood glucose was 9.3 mmol/l with HbA1c 10.9% and mild ketonuria but no DKA. Due to anamnestic data, pancreatic islet cell antibodies and C-peptide were measured. Treatment with lifestyle modification—diet to reduce weight, with basal insulin detemir and metformin—was recommended. After one week, C-peptide came around the low reference range limit (0.30 nmol/l), and IA-2, ICA, and GADA antibodies all came back positive. Three weeks later, the patient came for a check-up after she found out she was pregnant. Since pregnancy, insulin treatment was continued with a basal bolus insulin regime and strict control of glycemia was targeted. The patient refused the insulin pump and continued to use the CGM Dexcom One Plus. Detemir two times daily with aspart insulin before meals were given, and the patient had satisfactory levels of blood glucose with a fasting glucose level usually below 6 mmol/l and PPG < 8 mmol/l. Nine months later, the patient gave birth naturally to a healthy baby girl weighing 3 kilograms. Shortly after delivery, the patient had hypoglycemia, so insulin therapy was discontinued completely. Since she continued to use the Dexcom One Plus glucose sensor and glycemic values were continuously within limits, she discontinued any medication and came for a diabetologist check-up one month after delivery. Since this situation seemed to be a complete remission of type 1 diabetes, C-peptide and pancreatic islet cell antibodies were measured again. Now C-peptide arrived within normal values (1.12 nmol/l) with still positive anti-insulin antibodies in repeated measurements. The patient was advised to preserve lifestyle and diet measures and to take metformin since she was obese and did not breastfeed. The patient will continue to be under diabetologist care since her diagnosis of diabetes mellitus type 1 is established, and insulin treatment is expected to be necessary again once the honeymoon period passes. We present this case since it is not usual for obese adult women with prior GDM and a family history of type 2 diabetes mellitus to develop type 1 DM and even less often to develop complete remission shortly after delivery and pregnancy.

Diabetic ketoacidosis secondary to immunotherapy-induced diabetes mellitus

Athanasios Kasotas[1], Grigoris Effraimidis[2], Nektarios Adamopoulos[1], Maria Galani[1], Eleni Georgiou[1], Ioannis Gkountios[1], Anastasia-Konstantina Sakali[1] & Alexandra Bargiota[2]
[1]Department of Endocrinology and Metabolic Diseases, University General Hospital of Larissa, Larissa, Greece; [2]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department of Endocrinology and Metabolic Diseases, University General Hospital of Larissa, Larissa, Greece

Introduction
Immune checkpoint inhibitors have changed the landscape of cancer therapy by targeting proteins that regulate immune checkpoints. However, their use is accompanied by adverse events, including endocrinopathies and diabetes mellitus (DM), which can be initially presented with diabetic ketoacidosis (DKA). We present here two cases of DKA in patients on immunotherapy for cancer.
Cases: 1
A 57-year-old man with not known DM and with non-small cell lung cancer, developed after 7 months on PD-1 checkpoint inhibitor (nivolumab), altered consciousness, tachypnea and vomiting. The laboratory findings, pH: 7.15, HCO3-: 11.8 mEq/l, blood glucose: 367 mg/dl and blood ketones > 8 mmol/l, confirmed the diagnosis of DKA. He was managed with intravenous fluids and

insulin with resolution of acidosis. Additional tests results included HbA1c:7.3%, negative anti-GAD, anti-islet and anti-insulin autoantibodies and a C-peptide:0.47 ng/mL. The patient was put on a 4 injection regimen and his blood glucose is well controlled. 2. A 52-year-old male, with no history of diabetes and bladder carcinoma, developed one month after starting PD-L1 checkpoint inhibitor (durvalumab), DKA with abdominal pain, polyuria and weight loss, pH: 7.09, HCO3-: 7.3 mEq/l, blood glucose: 436 mg/dL and HbA1c:9%. After hydration and insulin therapy, acidosis was restored within 24 hours. Anti-GAD, anti-islet and anti-insulin autoantibodies were negative and c-peptide:0,41 ng/ml. The patient was discharged on an intensified insulin regimen.

Discussion

DM is a rare but it can be a life-threatening complication of immunotherapy. Real world data show an incidence of 2% and a mean age of onset at 60 years. Initial presentation varies but in 70% of the cases, DKA is the presentation at diagnosis, due to rapid destruction of beta cells by the immune system. Due to the almost complete pancreatic beta cells' destruction, ICI-DM is insulin-dependent. Doctors in charge of patients undergoing immunotherapy, should be on high alert, in order to recognize and treat on time this sudden and potentially life-threatening condition, optimising prognosis and minimizing disease complications.

Impact of gestational diabetes and maternal obesity on fetal growth: reduced length and cephalic circumference

Nayely Garibay Nieto[1], Isabel Omaña Guzmán[1], Berenice Palacios González[2], Elena Zambrano González[3], Thelma Rizo Pica[4], Luis Lanz Pérez[1], Emilia Lozano González[1], Ana Méndez Carballo[1], Mónica Zavala Serrat[1] & Javier Girón López[4]

[1]Hospital General de México "Dr. Eduardo Liceaga", Pediatric Obesity Clinic and Wellness Unit, Mexico City, Mexico; [2]Instituto Nacional de Medicina Genómica, Laboratorio de Envejecimiento Saludable del INMEGEN en el Centro de Investigación sobre el Envejecimiento, Mexico City, Mexico; [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Biología de la Reproducción, Mexico City, Mexico; [4]Hospital General de México "Dr. Eduardo Liceaga", Servicio de Patología, Mexico City, Mexico

Introduction

Maternal obesity is a global public health concern, and gestational diabetes mellitus (GDM) stands as the most common pregnancy complication. Both conditions are linked to adverse outcomes in offspring, including increased birth weight and an elevated risk of developing obesity and chronic diseases later in life.

Objective

To evaluate the association of maternal obesity and GDM with fetal growth indicators at birth and placental weight.

Methods

This cross-sectional analysis is based on data from mother-child dyads attending the Gynecology Service at Hospital General de México. The inclusion criteria were: 1) singleton pregnancy, 2) maternal age $\geq$18 years, and 3) either gestational diabetes mellitus (GDM) or an uncomplicated pregnancy. Women with systemic diseases or preeclampsia were excluded. Maternal and newborn data were obtained from clinical records. Fetal growth indicators included birth weight, birth length, abdominal circumference, and cephalic circumference. Descriptive analyses were conducted to characterize the study sample, and multiple linear regression models were used to evaluate the association of GDM and maternal obesity with fetal growth indicators. The models were adjusted for maternal age, newborn sex, gestational age at birth, and gestational weight gain. An interaction between GDM and pre-gestational BMI category were tested to evaluate if having both conditions affected the association with growth indicators. All analyses were performed in STATA 15. This research receive funding from the Secretaría de Educación, Ciencia, Tecnología e Innovación (SECTEI/1492023).

Results

A total of 74 mother-child dyads were included in the study. Among them, 39.2% (n= 29) had GDM, while 60.8% (n= 45) had normoevolutive pregnancies. The mean maternal age was 25.9 (6.2) years. Newborns of mothers with GDM were shorter (β=-1.08, P = 0.045) compared to those of mothers without GDM. Regarding cephalic circumference, newborns of mothers with obesity had larger values (β=1.6, P = 0.027). However, the interaction term with GDM was significant (β=-1.9, P = 0.078), indicating that when both conditions were present in mothers, the cephalic circumference was reduced compared to newborns of mothers without obesity and GDM. Neither GDM nor maternal obesity were associated with birth weight, abdominal circumference, or placental weight.

Conclusions

GDM was associated with a reduction in birth length, while maternal obesity was linked to an increased cephalic circumference. However, when both GDM and obesity were present in mothers, newborns had a significantly smaller cephalic circumference. These findings suggest that GDM may negatively impact fetal growth.

Solving a hypoglycaemia mystery

Zhi Wen Loh[1] & Hian Liang Huang[2]

[1]Tan Tock Seng Hospital, Endocrinology, Singapore, Singapore; [2]Singapore General Hospital, Department of Nuclear Medicine and Molecular Imaging, Singapore, Singapore

A previously well 22-year-old female with no medical history presented obtunded to the emergency department. Capillary blood glucose returned "LO" with corresponding venous glucose at 2.1mmol/l. Prompt reversal of severe hypoglycaemia led to full resolution of symptoms. She continued to have multiple episodes of hypoglycaemia daily during her inpatient stay. Biochemistry revealed the cause of hypoglycaemia to be endogenous hyperinsulinaemia, accompanied with a clean toxicology screen and negative insulin antibody assessment. Interestingly, she was also hyperthyroid and concomitantly diagnosed with Graves' Disease at the same encounter. Further history suggested that she may have had the hypoglycaemia disorder since early childhood for which she had been compensating for with lifestyle interventions. Genetic testing for congenital hyperinsulinaemia was inconclusive. Medical therapy with Diazoxide was initiated with good effect, with dose adjustments aided by continuous glucose monitoring. Etiology of hyperinsulinaemia was rigorously assessed, first with anatomical imaging of the pancreas (computed tomography and magnetic resonance imaging), followed by endoscopic ultrasound, all of which returned no positive result. Eventually, functional imaging with Exendin-4 PET/CT suggested a more diffuse process consistent with pancreatic islet cell hyperplasia.

Mucormycosis infections in a child with type 1 diabetes mellitus

Nur Rochmah[1], Deasy Fiasry[2], Rayi Kurnia Perwitasari[3], Yuni Hisbiyah[1] & Muhammad Faizi[3]

[1]Universitas Airlangga, Department of Pediatrics, Surabaya, Indonesia; [2]Airlangga University, Child Health, Soetomo hospital, Surabaya, Indonesia; [3]RSUD Dr. Soetomo, Department of Pediatrics, Surabaya, Indonesia

Background

A relatively uncommon infection, mucormycosis, in diabetes, stood out as the main underlying medical comorbidity for the infected patients. It was determined to be an independent risk factor for severe infection depending on which organ was affected. Mucormycosis detects several host-dependent clinical manifestations. Factors that impede host immune function can also play a role in the aggressiveness of mucormycosis infection. Mucormycosis have also been well studied with regard to the effects of hyperglycemia, and acidosis on their pathogenesis. The purpose of this paper is to present a case successfully management of type 1 diabetes mellitus (DMT1) with mucormycosis.

Case

S, a 10-year-old girl, was admitted to Soetomo Hospital, East Java, Indonesia, with complaints of fever accompanied by abdominal pain and a subsequent loss of consciousness. The patient was diagnosed with diabetic ketoacidosis (DKA) and type 1 diabetes mellitus (HbA1c 9.9%, blood glucose 478 mg/dL). Further examination revealed the presence of a white plaque on the soft palate (palatum molle) along with a perforation in the area. Additionally, the patient exhibited facial paralysis on one side. Laboratory findings and investigations conducted revealed the following: a pathological anatomy biopsy indicated chronic suppurative inflammation consistent with a nonspecific abscess; the C-peptide level was 0.193 ng/mL; ASTO was 315.27 IU/mL (normal range: $<$ 200 IU/mL); the anti-dsDNA antibody test was negative; blood culture was sterile, and urine

culture revealed the presence of *Candida glabrata*. A palatal swab culture identified *Candida dubliniensis* and mucormycosis. Additionally, *Acinetobacter baumannii* was detected in the palatal swab. The patient only received a 3-day treatment due to difficulties in obtaining amphotericin-B. However, she underwent surgical debridement performed by the surgery department to aid in wound healing. Despite the limited treatment duration, the patient successfully recovered, and the wound healed completely. After a few months of recovery and rehabilitation, patients can walk and eat well and go to school again.

Conclusion

Early diagnosis for mucormycosis is a key to rapid and appropriate treatment and better outcomes. Underlying risk factors influence the clinical presentation. The cornerstone for management of invasive mucormycosis involves surgical debridement and antifungal therapies.

Renal complications in diabetic subjects

Rihab Ben Abdallah Kolsi[1], Mouna Elleuch[2] & Kolsi Boulbaba[2]
[1]Faculty of Sciences of Sfax Tunisia, Sfax, Tunisia; [2]CHU Hedi Chaker Sfax Tunisia, Sfax, Tunisia

Today, diabetes mellitus is a major public health problem. Type 2 diabetes is the most common form, accounting for around 90% of all forms of diabetes. The ever-increasing frequency of this condition may be explained by lifestyle changes, particularly sedentary lifestyles, high-fat diets, obesity and an ageing population. The seriousness of this condition is linked to the occurrence of metabolic, infectious and degenerative complications, including renal manifestations. The aim of our work was to determine the distribution of diabetes according to sex, age and renal complications, and to study certain biochemical parameters of the glycemic and renal balance of people with diabetes and/or diabetic nephropathy ($n = 65$). We found that the risk of diabetic nephropathy was higher in women than in men, and that 11% developed renal complications. 86% had above-normal fasting blood glucose levels, and blood glucose levels were higher in those with ND (2.52 ± 0.95 g/l) than in patients without ND (1.92 ± 0.72 g/l). 85% of patients had HBA1c values above threshold, and mean HBA1c was higher in those with ND ($9.2 \pm 2.24\%$) than in those without ND ($8.28 \pm 1.60\%$). In addition, 47% had hypercreatininemia, of whom 11% had ND and 7% had hypocreatinemia. Hyper-uremia was present in 56% of patients, of whom 15% had ND, and 45% of patients had hyper-uricemia, of whom 10% had ND. It also appeared from our results that renal workup is effective in estimating function as well as the degree of renal complication.

Key words

Diabetes, nephropathy, glycemia, HBA1c, creatinemia, uremia, uricemia.

Effects of weight loss after bariatric surgery on pregnancy outcome

Tamar Shervashidze[1,2], Rusudan Kvanchakhadze[1], David Abuladze[3], Liana Jashi[4], Khatuna Chakvetadze[5] & Nino Lazrishvili[6]
[1]Davit Agmashenebeli University of Georgia, Tbilisi, Georgia; [2]David Metreveli Medical Center, Tbilisi, Georgia; [3]David Abuladze Georgian-Italian Clinic, Tbilisi, Georgia; [4]Avicena" Batumi Medical University, Batumi, Georgia; [5]"Reproart"- Clinic, Kutaisi, Georgia; [6]Innova Medical Center, Tbilisi, Georgia

Background and aims

Overweight and obese women have an increased risk of spontaneous miscarriage as Type 2 (T2DM) diabetes mellitus is associated with increased rates of adverse maternal and neonatal outcomes. Adverse outcomes are more common in women with pregestational diabetes compared to GDM. Obesity, with its associated metabolic and endocrine aberrations, can directly influence the reproductive health of women. Bariatric surgery, which is primarily designed to induce significant weight loss, has been shown to have a positive impact on fertility outcomes

Methods

The patient was diagnosed with type 2 diabetes at the age of 29. At the age of 33, she gave birth to a dead fetus in the 7th month of pregnancy with fetal hydrocephalus. At that time BMI -50kg/m2. The second pregnancy at the age of 38 ended with spontaneous abortion at 7 weeks. BMI -52.1 kg/m2. Insulin therapy was used during both pregnancies. Diabetes mellitus was controlled before and after pregnancy. Bariatric surgery was performed at the age of 40. BMI -53.3 kg/m2. After 4 years BMI -33.3kg/m2. Secondary infertility was established. Pregnancy with twin fetuses occurred through *in vitro* fertilization. Diabetes was managed with insulin. 2 healthy newborns were born by cesarean section at 34 weeks of pregnancy

Results

Significant weight loss in obese T2DM patients after bariatric surgery was associated with a substantial reduction in BMI from 53.3.5 kg/m^2 to - 33.3 kg/m2. Gradual weight loss has been shown to improve fertility and outcomes of fertility treatments and reduce cardiovascular and diabetes-associated morbidity and mortality

Conclusion

Women should be advised pre-pregnancy about the impact of being obese and risk of early pregnancy complications. Epidemiological evidence suggests an increased risk of both spontaneous and recurrent pregnancy loss with obesity. The ESHRE guidance recommends that couples with obesity and previous repeated pregnancy loss achieve a normal range BMI (20–25 kg/m2 for White individuals) before conceiving. A normal BMI can be associated with multiple health benefits for both mother and baby.

Kyrle's disease: a rare complication of diabetes (case report)

Wafa Atbib[1], Sana Rafi[1], Sara Ijdda[1], Ghizlane El Mghari Tabib[1] & Nawal El Ansari[1]
[1]Mohammed VI University Hospital, Endocrinology, Diabetology, Metabolic Diseases and Nutrition Department, Marrakech, Morocco

Introduction

Kyrle's disease (MK) belongs to the group of acquired perforating dermatoses. It is a rare pathology characterized by transepidermal removal of keratotic material. We report the case of a diabetic patient with MK.

Observation

This is a 47-year-old patient, diabetic for 15 years on insulin at the degenerative complication stage: hypertensive for 3 years and chronic renal disease for 2 years on treatment, amputation of the right big toe 6 years ago. Consulted for multiple ulcerated nodules of the lower limbs for several months, with loss of substance in the pulp of the big toe. The whole evolving in a context of feverish sensations and conservation of the general state. clinical suspicion of the diagnosis was confirmed by histological examination of a skin biopsy. This revealed a crater-shaped lesion filled with keratotic material, showing an image of incipient epidermal elimination on one cut level. The epidermis was acanthosic with significant compact parakeratotic hyperkeratosis and a slightly inflammatory dermis. The diagnosis of MK was therefore accepted. The patient was put on emollient and antihistamines.

Discussion

Acquired perforating dermatoses are rare pathologies characterized by transepidermal elimination of certain dermal constituents. Acquired MK is characterized by an invagination of the epidermis with keratotic content. MK is often associated with diabetes mellitus (50%) and chronic end-stage renal disease (70%). Diabetes is in the insulinocarrying stage. The pathophysiology of MK is still unknown, but hypotheses have suggested the role of cutaneous trauma and diabetic vasculopathy. Treatment is mainly symptomatic, based on emollients and keratolytics. Other options include topical or systemic retinoids, surgery or CO2 laser and phototherapy.

Conclusion

MK is a rare papulokeratotic dermatosis. It should be particularly sought after in diabetics. Diagnosis is confirmed by histology.

Stress perception among patients with type 1 diabetes

Majda El Baidouri[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]CHU Ibn Rochd, Clinical Neurosciences and Mental Health Laboratory, Faculty of Medicine and Pharmacy, Hassan II University, Casablanca, Morocco, Department of Endocrinology, Metabolic Diseases, and Nutrition, Casablanca, Morocco

Introduction

Stress is often a part of every individual's life. Living with a chronic illness such as type 1 diabetes adds an additional layer of stress and negative burden.

Objective
To assess the level of stress in a population of patients with type 1 diabetes.
Materials and methods
A cross-sectional descriptive study using the Perceived Stress Scale (PSS) questionnaire, which evaluates the level of stress based on feelings and thoughts over the past month. The PSS comprises 10 items, with a total score calculated out of 40.
Results
Our study included 71 patients with an average age of 25.42 ± 8 years and a sex ratio of 1.09. The average duration of diabetes was 8.59 ± 6.8 years, and the mean HbA1c level was 11.07 ± 4%. In our population, 60% of the participants were considered to have a high level of stress, while 40% were deemed to have a moderately high level of stress. None of the patients were categorized as having a low level of stress. The average stress level in the population was 24, identified as a moderate overall level. Among the patients, 50% reported feeling irritated quite often due to events beyond their control, and 38% felt upset by an unexpected event. Only 4 patients expressed confidence in their ability to manage personal problems, and only 6 believed that things were going their way.
Conclusion
Thus, more than half of the studied population suffers from high stress levels, representing an additional burden with implications for both disease management and the overall health of individuals.

Tracing the causes: why hypoglycemia strikes in type 1 diabetes mellitus

Yesmine Elloumi[1], Fedia Boubaker[1], Houcem Elomma Mrabet[1], Najoua Lassoued[1], Baha Zantour[1], Alaya Wafa[1] & Habib Sfar[1]
[1]Taher Sfar University Hospital, Mahdia, Tunisia

Background
Hypoglycemia is one of the most challenging and potentially dangerous complications faced by individuals with Type 1 Diabetes Mellitus (T1DM). Episodes of low blood glucose not only jeopardize immediate health but also complicate long-term diabetes control. Patients living with this condition may experience a loss of autonomy, anxiety, and fear of the next hypoglycemic event, which impacts their daily lives. Understanding why hypoglycemia occurs is critical for improving treatment strategies and overall patient outcomes.
Methods
This retrospective, descriptive study included patients with T1DM experiencing recurrent hypoglycemia who were hospitalized in the Endocrinology Department of Taher Sfar University Hospital in Mahdia, Tunisia, over a seven-year period.
Results
This study included 42 patients, with a mean age of 42 ± 25 years, the majority of whom were female (71%). The average glycated hemoglobin level was 10.7%. Notably, 26.7% of the patients were receiving insulin analogs. At the time of hospitalization, the mean insulin dose was 0.77 IU/kg/day, which decreased to 0.61 IU/kg/day upon discharge. Hypoglycemia was observed as moderate in 35% of cases and severe in 29%, occurring at a frequency of two episodes per week. The causes of hypoglycemia were multifactorial, with adrenal insufficiency being the most common, affecting 84% of the patients, as reflected in a mean early morning cortisol level of 82 µg/l. Additionally, 6.25% of patients had profound hypothyroidism, while no cases of hepatocellular insufficiency were found. Renal insufficiency was noted in 12.5% of patients, and 3 patients had malabsorption due to celiac disease. Insulin doses exceeding 1.5 IU/kg/day were noted in 21.9% of the cases, and 22.7% exhibited lipodystrophic regions. Moreover, 3 patients experienced hypoglycemia due to toxic factors, particularly alcohol abuse, and 2 patients (6.3%) presented with factitious hypoglycemia.
Conclusion
Hypoglycemia in T1DM poses significant challenges to patient management and quality of life. Understanding its multifactorial causes is crucial for developing targeted strategies to prevent and better manage this complication.

Antidiabetic treatment patterns in type 2 diabetic patients with metabolic associated steatotic liver disease

Yesmine Elloumi[1], Mouna Elleuch[1], Hamdi Frikha[1], Khouloud Boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Metabolic Associated Steatotic Liver Disease (MASLD) is increasingly recognized as a common comorbidity in patients with type 2 diabetes mellitus (T2DM), complicating their management. The presence of MASLD may influence choice and effectiveness of antidiabetic pharmacotherapy, as certain treatments may have varying impacts on both liver function and glucose control. This study aims to explore the pharmacotherapeutic profile of T2DM patients with MASLD.
Methods
A retrospective, descriptive, and analytical study was conducted on 202 T2DM patients followed at the Endocrinology Department of Hedi Chaker Hospital in Sfax, Tunisia. The patients were equally divided into two groups based on the presence or absence of MASLD.
Results
Hygienic and dietary measures without pharmacotherapy were recommended for 14.9% of patients. Nearly half of the patients (48.5%) received exclusive oral pharmacotherapy, while 21.8% were treated with insulin therapy, either as monotherapy (12.9%) or in combination with oral antidiabetic agents (8.9%). Metformin was the most frequently prescribed medication, used in 57.4% of cases, followed by sulfonylureas, prescribed in 27.7% of cases—glimepiride in 15.8%, glibenclamide in 7.9%, and gliclazide in 4%. The use of newer antidiabetic drugs was limited, with only two patients receiving SGLT2 inhibitors, specifically dapagliflozin, and no patients on empagliflozin. Incretin mimetics (DPP-4 inhibitors and GLP-1 agonists) were not prescribed. Acarbose was used in 2% of cases, and glinides in 5%. Among insulin treatments, human insulin was more commonly prescribed (17.8%) compared to insulin analogs (4%). The most frequent therapeutic combinations in this population were metformin with sulfonylureas (25.7%) and insulin with metformin (10.9%). Antidiabetic treatments were not associated with the development of MASLD for oral medications (metformin: $P = 0.131$, sulfonylureas: $P = 0.557$). However, insulin therapy was significantly associated with the absence of MASLD lesions in diabetic patients ($P = 0.027$).
Conclusion
Understanding the nuances of antidiabetic treatment of diabetic patients with MASLD is crucial for optimizing patient care and improving therapeutic strategies.

Type 2 diabetes-related features in patients with metabolic associated steatotic liver disease

Yesmine Elloumi[1], Mouna Elleuch[1], Younes Derbel[1], Khouloud Boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Mejdoub Rekik[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Type 2 Diabetes Mellitus (T2DM) is a chronic metabolic disorder commonly associated with various comorbidities, including Metabolic Associated Steatotic Liver Disease (MASLD). The overlap between these conditions presents significant challenges in both diagnosis and management. Understanding the specific diabetes-related characteristics in patients with T2D and MASLD is essential for improving clinical outcomes. This study explores the clinical features of T2DM patients with MASLD.
Methods
This retrospective study was conducted on T2DM patients with confirmed MASLD, who were followed at the Endocrinology-Diabetology Department of Hedi Chaker University Hospital in Sfax, Tunisia, over a 12-year period.
Results
This study was conducted on 101 diabetic patients. The mean age of diabetic patients with MASLD was 53.7 (±15.2) years, with a female predominance of 62.4%. T2DM was diagnosed at a mean age of 48 [40-57] years. They had a median HbA1c of 9% [6.8-11.3] and a median blood glucose level of 10.3 mmol/l [4.5-16.1]. After a median duration of 3 [0.7-10] years, 54.5% of these patients developed microvascular complications, while 31.7% had macrovascular complications. The most common microvascular complications were diabetic nephropathy (40.9%) and neuropathy (35.4%), followed by diabetic retinopathy (25.7%) and erectile dysfunction (23.1%). Positive albuminuria was detected in 35.6%, and impaired glomerular filtration rate (GFR) was observed in 27.7%,

predominantly at stages CKD-G3 (10.9%) and CKD-G4 (15.8%). Regarding macrovascular complications, ischemic heart disease (26.7%) and peripheral arterial disease (13.9%) were most frequently noted. Nearly half of the patients (48.5%) were treated with oral medications alone. In 21.8% of cases, insulin therapy was initiated, either as monotherapy (12.9%) or in combination with oral antidiabetic drugs (8.9%).
Conclusion
Our study provides insights into how the features of diabetes may contribute to the development and progression of MASLD.

Chronic kidney disease in type 2 diabetes patients with metabolic associated steatotic liver disease
Yesmine Elloumi[1], Mouna Elleuch[1], Maryem Akacha[1], Khouloud Boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Chronic kidney disease (CKD) is a common complication in type 2 diabetes mellitus (T2DM) patients, and its clinical profile may be altered by the presence of Metabolic Associated Steatotic Liver Disease (MASLD). While the association between these two conditions is increasingly recognized, their combined impact on renal function requires further investigation. This study aims to describe the CKD profile in T2DM patients with MASLD.
Methods
This retrospective descriptive study included T2DM patients with confirmed MASLD, followed from 2012 to 2024 at the Endocrinology-Diabetology Department of Hedi Chaker University Hospital in Sfax, Tunisia. The study focused on CKD, analyzing its stages based on glomerular filtration rate (GFR) and levels of albuminuria. Albuminuria was classified as mild (<30 mg/g of urinary creatinine), microalbuminuria (30–300 mg/g of urinary creatinine), and macroalbuminuria (proteinuria) defined as values exceeding these thresholds.
Results
We included 101 patients in this study. The mean age of patients was 53.7 ($\pm$ 15.2) years, with a female predominance of 62.4%. CKD-G1, defined by a GFR of $\geq$90 ml/min/1.73m^2, was observed in 43.6% of patients. In comparison, CKD-G2, characterized by a GFR ranging from 60 to 89 ml/min/1.73m^2, was found in 28.7% of the cases. Furthermore, CKD-G3, with a GFR between 30 and 59 ml/min/1.73m^2, was present in 10.9%, while CKD-G4, where the GFR ranged from 15 to 29 ml/min/1.73m^2, was identified in 15.8% of patients. Notably, CKD-G5, indicating a severe reduction in renal function with a GFR <15 ml/min/1.73m^2, was seen in only 1%. Regarding albuminuria, a normal to mildly elevated level was detected in 56.4% of patients, whereas microalbuminuria was observed in 35.6%, and proteinuria was found in 7.9%.
Conclusion
These findings collectively highlight the diverse renal involvement in this population, underscoring the need for vigilant monitoring and early therapeutic interventions.

Mycosis fungoides and diabetes mellitus: is there a link?
Oumaima Dimassi[1], Khouloud Boujelben[1], Mouna Elleuch[1], Malek Hadrich[1], Mouna Mnif[1], Nadia Charfi[1], Faten Haj Kacem Akid[1], Mohamed Abid[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Department of Endocrinology Hedi Chaker Hospital, Sfax, Tunisia

Background
Mycosis fungoides (MF) is the most common type of primary cutaneous T-cell lymphoma, often presenting with chronic nonspecific skin lesions that can mimic inflammatory dermatoses. Diabetes mellitus (DM) is a metabolic disorder frequently diagnosed incidentally during routine evaluations. The coexistence of MF and DM is rare, and their potential pathophysiological link remains unclear.
Case Presentation
A 63-year-old woman with a family history of hypertension and type 2 diabetes mellitus, and a personal history of dyslipidemia, treated with atorvastatin, presented with progressive, pruritic, erythematous plaques with fine scaling, well-demarcated pigmentation, and atrophic hypopigmented areas. Some lesions exhibited a wrinkled skin appearance. These lesions had been evolving over the past nine months with diffuse involvement of the trunk and extremities. A skin biopsy was performed at the Department of Dermatology and histopathological analysis with immunohistochemistry confirmed the diagnosis of mycosis fungoides. The patient was started on topical corticosteroids and retinoids. During the diagnostic workup, routine laboratory investigations revealed newly diagnosed diabetes mellitus. The patient was subsequently initiated on oral antidiabetic therapy. Under treatment, her glycemic control improved, and her cutaneous lesions stabilized.
Discussion
MF is characterized by dysregulated T-cell activation, leading to increased levels of pro-inflammatory cytokines such as TNF-α, IL-6, and IL-17. These cytokines are also implicated in insulin resistance and β-cell dysfunction in DM. Chronic immune stimulation in MF could contribute to metabolic disturbances, potentially increasing the risk of DM.
Conclusion
This case highlights the importance of metabolic screening in patients presenting with unexplained dermatological symptoms. Further research is needed to explore potential links between mycosis fungoides and diabetes mellitus.

Diabetic retinopathy in normoalbuminuric patients with type 2 diabetes mellitus: any predictive factors?
Hadhemi Belhassen[1], Ramla Mizouri[1], Rym Ben Othman[1], Siwar Saoudi[1], Faten Mahjoub[1], Berriche Olfa[1], Nadia Ben Amor[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, A, Tunis, Tunisia

Introduction
As far as known today, microalbuminuria is an independent risk factor for the prevalence of diabetic retinopathy (DR) in patients with type 2 diabetes mellitus (DM). For this reason, the clinical significance of DR in normoalbuminuric type 2 DM patients may be overlooked. The aim of this study was to investigate the prevalence of DR and predictors for DR in normoalbuminuric patients with type 2 DM.
Methods
Descriptive cross-sectional study conducted over 3 months in department A of The National Institute of Nutrition of Tunis which included patients with type 2 diabetes mellitus.
Results
Sixty-two patients were included amongst whom 36 were women and 26 men. The characteristics of the patients were respectively: age: 58 ± 11 years, Body Mass Index: 28 ± 6.1 Kg/m^2. Twenty-seven patients had a DR as a complication of diabetes. The onset of diabetic retinopathy was correlated with age, with a statistically significant correlation ($P = 0.017$). There was no statistically significant correlation between DR and gender ($P = 0.54$), smoking status ($P = 0.7$), Body mass index ($P = 0.48$), duration of diabetes progression ($P = 0.12$), HbA1c ($P = 0.2$).
Conclusions
Our findings suggest that patients with normoalbuminuric type 2 DM also require close monitoring for the early detection of DR, for all patients especially in case of increasing age. There is no specific glycaemic or metabolic profile to prompt screening for DR.

Vitamin D status in type 1 diabetic tunisian patients: a case-control study
Nour Hentati[1], Faten Mahjoub[1], Maryam Naifar[1], Ramla Mizouri[1], Rim Rachdi[1], Rim Ben Othman[1] & Henda Jamoussi[1]
[1]National Institute of Nutrition of Tunis, Tunis, Tunisia

Background
Vitamin D, a fat-soluble vitamin, is essential for calcium homeostasis and bone health, but emerging research highlights its broader role in immune function, inflammation, and metabolic regulation. Several studies have reported a high prevalence of vitamin D deficiency in individuals with type 1 diabetes (T1D).

Objective
The aim of this study was to assess 25-hydroxy vitamin D (25(OH)D) levels in Tunisian T1D patients, comparing them with those of healthy control subjects.
Methods
We conducted a case-control study including 50 patients with T1D and 50 healthy controls matched for age, sex and body mass index, recruited from the general population. All participants underwent measurement of serum (25(OH)D) levels.
Results
The median age was 26 years [21.00 – 31.75] for the diabetic group and 25 years [22.00 – 30.75] for the control group ($P = 0.95$). A slight female predominance was observed, with 56% ($n = 28$) of participants being female in both groups. The mean 25(OH)D level was 11.14 ± 6.49 ng/ml in the diabetic group and 11.67 ± 6.11 ng/ml in the control group, with no statistically significant difference between the two groups ($P = 0.67$). Vitamin D insufficiency, defined by 25(OH)D levels <30 ng/ml, was identified in 98% of diabetic patients and in all control subjects. A confirmed deficiency, characterized by 25(OH)D levels <20ng/ml, was observed in 92% of diabetics and 94% of controls. Severe deficiency, with 25(OH)D levels ≤ 10 ng/ml, was present in 56% of the diabetic group and 42% of the control group with no statistically significant difference between the two groups ($P = 0.32$).
Conclusion
The prevalence of vitamin D deficiency was particularly high in both groups, highlighting the need for preventive measures such as public awareness campaigns and the promotion of vitamin D fortification of foods.

Acute pancreatitis in type 1 diabetic patients: etiological and evolutionary profile

Dhoha Ben Salah[1], Nada Hassairi[1], Kouloud Boujelben[1], Oumaima Dimassi[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Objective
This study aimed to describe the etiological and evolutionary profile of acute pancreatitis (AP) in type 1 diabetic (T1D) patients.
Patients and Methods
A retrospective descriptive study including 10 T1D patients who experienced at least one episode of AP during follow-up.
Results
The average age at T1D diagnosis was 19.7 ± 9.3 years, with a female predominance (60%). T1D was frequently first diagnosed through classic cardinal symptoms (50%) or spontaneous DKA (20%). In 10% of cases, T1D was diagnosed during an AP episode. AP occurred at an average age of 26.9 ± 14.9 years. AP was classified as stage E in 57.1% of cases, while stages A, B, or C were less frequently reported (14.3% each). Identified etiologies of AP included autoimmune causes (20%) and severe hypertriglyceridemia (10%). In 70% of cases, the underlying mechanism remained undetermined. Despite a favorable outcome after the first episode, AP recurrence was common in T1D patients, with a recurrence rate of 16.7%.
Discussion
The pathophysiological mechanism of AP in T1D patients remains poorly understood. The impact of AP on pancreatic tissue, already weakened by autoimmune destruction in T1D, may be more pronounced compared to non-diabetic individuals. Our study highlights an increased incidence of stage E AP and a higher recurrence rate in this population. Further studies with larger sample sizes are needed to provide more precise explanations.

Microbiota and type 2 diabetes: current status and future perspectives

Dorra Ben Salem[1], Khaola Sallem[1], Arwa Guediche[2], Syrine Daada[3] & Salma Mohsen[4]
[1]CHU Fattouma Bourguiba, Monastir, Tunisia; [2]CHU Fattouma Bourguiba, Department of Gastroenterology, Monastir, Tunisia; [3]CHU Fattouma Bourguiba, Department of Endocrinology and Internal Medicine, Monastir, Tunisia; [4]National Institute of Nutrition and Food Technology, Tunis, Tunisia

Introduction
Growing evidence underscores the pivotal role of gut microbiota (GM) in metabolic regulation, systemic inflammation, and insulin resistance, key factors in the development of type 2 diabetes (T2D). This systematic review aims to examine the causal relationship between GM composition and T2D, elucidate the underlying mechanisms, and explore potential microbiota-targeted therapeutic strategies for T2D management.
Materials and Methods
We performed a comprehensive literature review across PubMed, ScienceDirect, and Google Scholar to identify the most relevant studies. After removing duplicates, ten articles were included.
Results
Under normal conditions, the microbiota, particularly the GM, maintains a balanced state, ensuring a harmonious coexistence of its diverse microbial populations. Disruption of this balance leads to dysbiosis. In individuals with type 2 diabetes, GM composition is characterized by dysbiosis, which significantly impacts metabolic health and inflammation. Compared to healthy individuals, T2D patients exhibit notable alterations in their GM profile, including a reduction in beneficial butyrate-producing bacteria such as Faecalibacterium, Clostridium, and Akkermansia, along with an increase in opportunistic species like Escherichia coli and Bacteroides fragilis. The gut microbiota influences the progression of type 2 diabetes by increasing intestinal permeability, allowing harmful molecules such as lipopolysaccharides (LPS) to enter the bloodstream. This triggers systemic inflammation and disrupts insulin signaling. Additionally, GM alterations lead to changes in metabolite production, including an overproduction of branched-chain amino acids, imidazole propionate, and LPS, alongside a reduction in short-chain fatty acid (SCFA) synthesis. Given its critical role, GM modulation is considered a promising therapeutic target. Potential interventions include probiotics, prebiotics, synbiotics, and fecal microbiota transplantation.
Conclusion
In conclusion, gut microbiota plays a crucial role in the progression of type 2 diabetes (T2D) through various mechanisms. Future research should prioritize refining microbiota-targeted interventions, such as prebiotics, synbiotics, and fecal microbiota transplantation, to enhance T2D management and metabolic health.

Assessment of nutritional status in elderly diabetics in hospital

Ramla Mizouri[1], Rym Ben Othman[1], Rim Rachdi[1], Berriche Olfa[1], Faten Mahjoub[1,2], Nadia Ben Amor[1] & Jamoussi Henda[1]
[1]Institut National de Nutrition de Tunis, Service A, Tunis, Tunisia; [2]Institut National de Nutrition de Tunis, Tunis, Tunisia

Introduction
The assessment of the nutritional status of elderly diabetics is essential; it makes it possible to detect undernutrition which could increase morbidity and mortality and prolong the duration of hospitalization. The objective of this study was to evaluate the nutritional status of elderly diabetics.
Methods
This is a descriptive study carried out on 50 hospitalized elderly type 2 diabetics. The assessment of nutritional status was based on the Mini Nutritional Assessment (MNA) questionnaire.
Results
The average age of patients was 69.36 years with a female predominance (74%). The average BMI was 26.7 kg/m2. The average duration of diabetes progression was 15 years with an average HBA1c of 10.2%. Half of the patients aged between 65 and 80 years presented a risk of malnutrition (score: 17 to 23.5), while all subjects aged over 80 presented this risk. However, we did not find a correlation between age and nutritional status ($P = 0.44$). Nearly two thirds of women (60%) were at risk of malnutrition. This risk is twice as high as in men ($P = 0.04$). We did not find a correlation between the duration of diabetes and nutritional status.
Conclusion
Undernutrition in elderly diabetics is associated with increased morbidity and mortality and impaired quality of life. This observation justifies the imperative of an early assessment of nutritional status using the MNA questionnaire which must be part of the gerontological examination.

Type 2 diabetes diagnosed after 10 years of insulin therapy

Elsayed Ghonamy Mahros Ismail[1]
[1]Faculty of Medicine Ain Shams University, Cairo, Egypt

Background
Diabetes is a major global health problem, Until recently, immune-mediated type 1 diabetes mellitus was the only type of diabetes considered prevalent among children, now type 2 diabetes accounts for about 15% to 45% of all newly diagnosed cases of diabetes in children and teenagers (1). This could be due to the pandemic of obesity in childhood (2).
Case Report
29 years old male patient diabetic 10 years ago presented with uncontrolled diabetes HbA1c 8.4 % on multiple daily injections. BMI 32 kg/m^2 and had acanthosis nigricans on the neck. We introduce metformin 2gm/day and decrease dose of insulin. He came on the next week with decreased attacks of hypoglycemia. We ordered C peptide and it was found normal hence we gave dulaglutide 1.5 weekly with metformin and decreased insulin gradually based on blood glucose. Three months later we stopped insulin and patient BMI 26 kg/m^{2}and HbA1c 5.8 % on metformin and dulaglutide.
Discussion
Type 2 diabetes mellitus had always been considered a disease of older adults, while type 1 diabetes mellitus, was considered a disease of children (3). That is why our patient was misdiagnosed and managed as a case of type 1 diabetes. There has been an increase in the incidence of T2DM in children and adolescents. This is due to a rise in prevalence of obesity in adolescents (4). Presence of obesity, acanthosis nigricans and normal C peptide level confirmed our diagnosis(5)
Conclusion
We should raise awareness among clinicians that type 2 can occur in young adult and children to avoid mismanagement of diabetes.

Impact of vitamin d and vitamin d receptor activator in diabetic nephropathy

Merita Emini Sadiku[1]
[1]University of Prishtina "Hasan Prishtina", Medical Faculty, Clinic of Endocrinology, Prishtina, Kosovo, Prishtina, Kosovo

Vitamin D is a hormone which is involved in many physiological processes in addition to bone metabolism and the muscular system. Based on several animal and human studies, it has been established that vitamin D plays an important role in the development of diabetic nephropathy (DN). DN is a frequent and severe chronic microvascular complication of diabetes mellitus (DM). As such, DN and cardiovascular complications are considered the main risk factors for the death of patients with DM. Recent studies have shown the renoprotective effect of vitamin D and its receptor (VDR) based on its effect on endothelial function, preservation of podocytes, anti-inflammatory effect, and direct influence on the renin-angiotensin aldosterone system. The renoprotective effect of Vitamin D has been shown to potentially delay the onset of DN, which is the main cause of end stage renal diseases (ESRD). The impact of vitamin D on the recovery of already existing kidney damage is debatable and doubtful. Increasing evidence has shown that the VD/VDR interaction possesses a series of renoprotective effects in DN patients based on the anti-proteinuric, anti-fibrotic, and anti-inflammatory effect, as well as the preventive effect of podocyte damage. Based on this important renoprotective effect, important data for therapeutic and effective methods for DN have also been presented. It was performed a structured search of published research literature for several databases regarding the impact of vitamin D on the pathophysiology of diabetic nephropathy as well as its therapeutic implications in terms of renoprotection of VD and VDRA in animal research and human clinical research as RCT, reviews and meta-analyses over the last decade.

Targeted, rapid glycaemic control and its potential adverse outcomes

Augustė Pikelytė[1] & Diana Šimonienė[2]
[1]Faculty of medicine, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Department of Endocrinology, Kaunas, Lithuania

Introduction
Following delivery, insulin sensitivity doubles, and breastfeeding further lowers insulin needs, increasing the risk of severe maternal hypoglycaemia [1], particularly with prior hypoglycaemia unawareness [2]. This case describes a 28-year-old woman with uncontrolled type 1 diabetes (T1D) in early pregnancy, where tight glycaemic control during gestation led to fatal postpartum hypoglycaemia.
Case Presentation
The patient's pre-pregnancy HbA1c level was >10%, decreasing to 7.1% by 13 weeks of gestation and further to 5.7% at 31 weeks. Treatment with daily subcutaneous injections of insulin degludec and ultra-fast-acting insulin aspart was continued at the woman's request. At 31 weeks of gestation, the woman's continuous glucose monitor (CGM) indicated normoglycaemia 81% of the time, hyperglycaemia 20%, and hypoglycaemia 9%. Delivery at 37 weeks of gestation was uneventful, a healthy preterm infant weighing 2355 grams was born. The patient began breastfeeding promptly after delivery. Within 24 hours after delivery, the woman was found unconscious and without vital signs. CGM recorded hypoglycaemia at 2.2 mmol/l and later as low as 0.1 mmol/l. Prolonged hypoglycaemia likely contributed to altered consciousness, acute respiratory failure, and subsequent cardiac arrest.

Discussion
Guidelines from the American Diabetes Association and the National Institute for Health and Care Excellence recommend achieving a HbA1c level $<6.5\%$ before conception [3]. Poor glycaemic control and altered insulin sensitivities during pregnancy increase the risk of hypoglycaemia unawareness. Additionally, sudden changes in diabetes control can significantly impact pregnancy outcomes, increasing the risk of maternal and neonatal complications [4].
Conclusion
This case highlights the importance of pregnancy planning for women with T1D and hypoglycaemia unawareness, particularly after delivery when insulin sensitivity undergoes dramatic changes.

Unbalanced diabetes leads to orbital myositis with oculomotor nerve palsy (ONP)

Meriem Benrkia[1], Ghita Khamel[1], Fatima Toulali[1], Kaoutar Rifai[1], Hind Iraqi[1] & Mohamed El Hassan Gharbi[1]
[1]CHU Ibn Sina, Rabat, Morocco

Introduction
Orbital myositis remains a rare condition that typically presents in an idiopathic acute form in young adult females. However, atypical forms related to specific autoimmune and inflammatory conditions are increasingly recognized. We report the case of a female patient with poorly controlled diabetes who developed acute orbital myositis with oculomotor nerve palsy.
Observation
A 50-year-old woman with 10 years of poorly controlled diabetes mellitus was referred to the Endocrinology department of IBN SINA university hospital in RABAT for further treatment of severe acidosis decompensation due to a medication discrepancy. During hospitalization, the patient developed sudden-onset ptosis associated by pain in the left orbit. Ophthalmological examination of the left eye revealed oculomotor paralysis, including divergent strabismus, diplopia, and mydriasis. An emergency cranio-orbital CT scan was performed and found to be normal. Magnetic resonance imaging (MRI) of the orbit showed homogeneous thickening of the right medial oculomotor and the levator palpebrae superioris muscles of the left eye, with no other associated abnormalities, suggesting myositis of probably inflammatory origin. Biological tests revealed a moderate inflammatory syndrome. Etiological work-up, including thyroid, immunological, and infectious tests, was negative. The diagnosis of orbital myositis in a patient with unbalanced diabetes was therefore established. The patient was started on oral corticosteroids (1 mg/kg/day) and referred to the ophthalmology department for further management.
Discussion and Conclusion
Diabetic oculomotor nerve palsy (ONP) is a complication of diabetes mellitus with distinct clinical sequelae that can affect a patient's quality of life. Recent studies have confirmed that microvascular factors are responsible for nerve damage, leading to a loss of nerve function. Hyperglycemia causes microvascular alterations that reduce nerve perfusion and induce endoneurial hypoxia. Therefore, vasa nervorum dysfunction contributes to nerve ischemic injury during the development of diabetic neuropathy. Orbital myositis is a condition that most often occurs in middle-aged women. Its etiopathogenesis remains incompletely understood. The association with certain autoimmune diseases and small-vessel vasculitis suggests an immunological origin. Corticosteroid therapy remains the first-line treatment, with a good response, and an immunosuppressant can be added if necessary.

Barriers to achieving glycemic control in type 2 diabetes mellitus: focus on therapeutic adherence

Yesmine Elloumi[1], Ekram Hajji[1], Bilel Ben Amor[1], Zeineb Rekaya[1], Hanene Sayadi[1] & Ines Khochtali[1]
[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Background
Diabetes management is a multifaceted challenge influenced by treatment patterns, adherence to therapy, and patient-specific factors. Achieving optimal glycemic control is essential to reducing the risk of microvascular and macrovascular complications, yet many patients fail to meet recommended targets. Understanding the interplay between treatment patterns, adherence barriers, and their impact on glycemic control can provide valuable insights into improving diabetes care and outcomes.
Methods
This was a descriptive cross-sectional study conducted on 80 patients with type 2 diabetes mellitus (T2DM) patients who had been followed at the endocrinology outpatient clinic of Fattouma Bourguiba University Hospital in Monastir, Tunisia, for over six months.
Results
Among the 80 patients studied, 65% were female, with a mean age of 57.9 years. The average duration of diabetes was 12.83 years. Diabetes was complicated in 63.8% of cases, and 51.3% of patients were not meeting therapeutic glycemic targets. The mean HbA1c was $8.91\% \pm 2.08$. Microvascular complications were present in 57% of patients, and 23% were at secondary prevention. Adherence to antidiabetic treatment was influenced by several factors affecting glycemic control. These factors included hypoglycemia (10%), therapeutic inertia (2.5%), negligence (3.8%), and financial issues (3.8%). Additionally, digestive intolerance (12.5%), visual impairment (2.7%), and treatment unavailability (2.3%) further hindered patients' ability to follow their prescribed regimen. Moreover, forgetfulness (15%) and medication errors (1.5%) were also significant barriers.
Conclusion
Achieving glycemic control in patients with T2DM remains a significant challenge. Future strategies should focus on enhancing patient education, providing better access to medications, and addressing factors that hinder adherence.

Peri-esophageal infections due to foreign body in the esophagus: a serious complication in diabetic patients

Malika Omri[1], Nawress Thabet[2], Mouna Belakhdher[1], Jihene Houas[1], Abir Meherzi[1], Monia Ghammam[1], Hamza Elfekih[3], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, Department of ENT and Head and Neck Surgery, Sousse, Tunisia; [2]Farhat Hached University Hospital, ENT Department, Sousse, Tunisia; [3]Farhat Hached Hospital, Department of Endocrinology, Sousse, Tunisia

Introduction
Peri-esophageal infection is the most concerning complication of traumatic esophageal perforations. These perforations occur in 1-4% of cases involving esophageal foreign bodies, either spontaneously or during rigid endoscopic extraction. They can lead to severe infections such as cervical cellulitis and mediastinitis, posing life-threatening risks.
Objective
This study aims to analyze the specifity of peri-esophageal Infections clinical, paraclinical characteristics and their therapeutic management in diabetic patients.
Methods and Observations
A retrospective analysis of four cases with an age varying between 4 and 60 years, all 4 patients were diabetics and admitted for accidental ingestion of sharp foreign bodies. Patients presented with persistent solid dysphagia and subfebrile states.

Thoracic xray confirmed foreign bodies in three cases and suspected complications in one case. Endoscopic extraction identified esophageal perforations, while CT scans revealed cervical cellulitis (2 cases), prevertebral abscess (1 case), peri-esophageal abscess (1 case), and mediastinitis (1 case). Management included broad-spectrum antibiotics, absolute diet, surgical repair, drainage, or tracheotomy, depending on the case. All patients recovered fully over a three-year follow-up.
Conclusion
Clinicians must always consider esophageal perforation in cases of foreign body ingestion. Early imaging and appropriate therapeutic strategies are essential to prevent severe outcomes

Benefits of SGLT2 inhibitors on cardiovascular and renal health in clinical practice

Fatma Ben Abdessalem[1], Hamza Elfekih[1], Wiem Saafi[1], Sawsen Nouira[1], Sawssen Mrad[2], Imen Halloul[1], Taieb Ach[1], Salima Ferchichi[2], Ghada Saad[1] & Yosra Hasni[1]
[1]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Endocrinology Diabetology Department, 4000, Sousse, Tunisia, Sousse, Tunisia; [2]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Biochemistry Department, 4000, Sousse, Tunisia, Sousse, Tunisia

Background
SGLT2-inhibitors have revolutionized the management of type 2 diabetes mellitus by promoting urinary glucose excretion, thereby reducing blood glucose levels. Beyond their role in diabetes management, these agents have shown promise in mitigating cardiovascular and renal complications. This study aimed to evaluate the effects of SGLT2-inhibitors on glycemic control, renal function, and metabolic parameters in patients with diabetes.
Methods
A descriptive retrospective study was conducted at the Endocrinology Department of Farhat-Hached University Hospital in Sousse, Tunisia. The study included diabetic patients evaluated over two periods: P1 from January to March 2024 and P2 from March to June 2024. They were divided into two groups: those receiving SGLT2-inhibitor treatment in P2 (G1) and a control group (G2). All patients underwent fasting blood glucose (FBG), glycated hemoglobin (A1c), lipid profile, renal assessment, and microalbuminuria testing.
Results
A total of 72 patients were evaluated. G1 included 36 patients, and G2 also consisted of 36 patients. The mean age of participants was 64 ± 9.26 years in G1 and 62 ± 8.64 years in G2, with no significant difference ($P = 0.36$). Both groups had a female predominance (55.5%). Chronic imbalance of diabetes under insulin was the most common reason for admission (52.8%). During P1, no significant differences were observed in A1c, FBG, creatinine, or microalbuminuria between the groups. However, during P2, G1 demonstrated significantly lower A1c ($9.07\% \pm 1.82\%$ vs. $10.16\% \pm 1.40\%$, $P = 0.007$) and FBG levels (1.51 ± 0.57 g/l vs. 2.36 ± 0.80 g/l, $P < 10^{-3}$) compared to G2. Microalbuminuria was also significantly reduced in G1 (65 ± 111.18 mg/24h vs. 492 ± 1137.80 mg/24h, $P = 0.032$). No significant differences were noted in lipid profiles or creatinine levels between the groups.
Conclusion
SGLT2-inhibitors significantly improved glycemic control and reduced micro-albuminuria in diabetic patients, highlighting their potential to slow the progression of chronic kidney disease (CKD). Their efficacy and safety across CKD stages 1 to 4 position them as a promising therapeutic option for managing diabetes and its renal complications.

Cardiometabolic profile in type 2 diabetics with vitamin D deficiency

Ergita Nelaj[1], Irida Kecaj[1] & Kei Xhixhabesi[1]
[1]University Hospital Center "Mother Teresa", Internal Medicine, Tirana, Albania

Objectives
The diabetic patients are subjects at high cardiovascular risk. Vitamin D plays a significant role in minimizing chronic metabolic syndromes such as type 2 DM and cardiovascular diseases. Vitamin D deficiency increased CVD risk in poor glycemic control in diabetics. The objective of our study is to describe metabolic profile in type 2 diabetics with vitamin D deficiency and its associations with CVD.
Methods
Included a total of 64 type 2 diabetics in whom a vitamin D dosage was carried out. The presence of CVD was determined based on medical records. Control of diabetes was assessed based on HbA1C levels.
Results
The average age of our patients was 57.04 years ± 11.05. 45 patients had poor glycemic control and the other had good glycemic control. Patients with poor control had a significantly higher level of total cholesterol (TC), triglyceride (TG), and non-high-density lipoprotein lipase cholesterol (non-HDL-C), compared to patients with good glycemic control. Was observed significant negative correlation of vitamin D with lipid markers. Hyperuricemia was present in 20 patients. 65% of patients had high blood pressure under medication, 21 patients were on ACE- inhibitor or ARB, 9 on calcium channel blockers, 5 on thiazide diuretics and 7 on beta blockers.
Conclusions
Patients with T2DM who are at risk for diabetic complications under poor glycemic control should be advised for vitamin D measurement, and vitamin D supplementation may reduce the risk of CVD.

Hypoglycemia and autoimmune diabetes; a cause not to be

Malak Riznat[1], Siham Malki[1] & Guerboub Ahmed Anas[1]
[1]Hopital Militaire Mohamed V Rabat, Rabat, Morocco

Introduction
Hypoglycemia is a metabolic emergency that can increase micro and macrovascular complications through glycemic variability. The diagnostic approach differs according to the type of Through this observation, we report a racist cause of hypoglycemia in a type 2 diabetic subject.
Observation
This is a 34-year-old patient with type 1 diabetes since childhood, treated with basal bolus analogues with U100 glargine in the evening and insulin aspart before each meal, who presented in consultation for exploration of refractory hypoglycemia. The patient presented with hypoglycemia at 0.3 g/l, generally in the morning and not felt because of associated dysautonomia. This prompted a blood glucose holter test, which revealed hypoglycemia at dawn and late postprandially. The 1st-line workup for organic damage or autoimmunity was strictly normal, except for antiinsulin AC positivity. This positive assay incriminates first and foremost the type of insulin with an immunogenic effect in type 1 diabetics, a high-risk area. Our attitude was to switch to the least immunogenic and most stable insulin, i.e. degludec, with the result that hypoglycemic episodes disappeared completely.
Discussion and conclusion
Insulin is an immunogenic protein, and this same protein is the main autoantigen responsible for the onset of type 1 diabetes. When administered exogenously, i.e. in insulin-requiring subjects of any type of diabetes, the latter can lead to a pathogenic reaction that is all the more exaggerated when it occurs on a background of autoimmunity. Since the introduction of the latest-generation insulin analogues, the frequency of these reactions has fallen sharply. The use of these insulins should be considered when the etiological search for hypoglycemia is undetermined.

Pancreatic diabetes: diagnostic, therapeutic, and evolutionary particularities

Emna Naccache[1], Sawsen Essayeh[1], Rihab Laamouri[1], Sabrine Mekni[1], Nadia Mchirgui[1], Khiari Karima[1], Imen Rojbi[1] & Ibtissem Ben Nacef[1]
[1]Charles Nicolle Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
Pancreatic diabetes, or type 3c diabetes, is a specific form of diabetes caused by pancreatic dysfunction due to diseases affecting its insulin production capacity. It remains underdiagnosed, often leading to a delayed diagnosis. The aim of this study is to analyze the diagnostic, therapeutic, and evolutionary particularities of this form of diabetes.
Materials and Methods
This is a retrospective descriptive study including 12 patients followed for pancreatic diabetes at the endocrinology department of Charles Nicolle Hospital in Tunis between 2019 and 2024.

Results
The median age was 60 ± 11.6 years, with a male-to-female ratio of 11.5. The median duration of diabetes was 5 ± 6.7 years. Two patients had pancreatic cancer, while ten had pancreatitis, including four with acute pancreatitis and six with chronic pancreatitis. Additionally, four patients had a history of pancreatic surgery. Half of the patients were treated with basal human insulin and basal insulin analogs, and a quarter required rapid insulin. All patients had poorly controlled diabetes, with a fasting blood glucose level of 2.46 ± 1.56 g/l and an HbA1c of 10.2 ± 2.17%. Four patients exhibited unstable diabetes, with hypoglycemia occurring in approximately 30% of cases. Macrovascular and microvascular complications were present in half and one-third of the patients, respectively.
Conclusion
Pancreatic diabetes remains a rare form of diabetes that requires early diagnosis. Its management is challenging due to its instability, the very high risk of hypoglycemia, and its association with serious conditions, such as chronic pancreatitis or pancreatic tumors.

JOINT1184

Successful treatment of 138000 patients with multimodal drug approach

Kiumars Pirkalani[1]
[1]Mehr Medical Group, Internal Medicine, Tehran, Iran

Background and Aim
Guidelines of diabetes societies for type II DM in terms of dose and drug escalation are misleading. Fear of hypoglycemia has prevented early elaboration of multiple effective drugs. Clever, circadian based combination of drugs with low hypoglycemia risk added to slow release Glyclazide, suppressing Gut microbia, targeting Glut-4 expression, adding appetite suppressors have shown new horizons in DM treatment with complete normalization of HbA1C irrespective of baseline HbA1C, possibility of treatment cessation.
Methods
Auditory Insulin tolerance test explained before was used to predict effectiveness. In eight years of study, hundred and thirty eight thousands patients received Sitagliptin 100mg at noon, Glucophage 500mg and Empagliflozin 12.5mg BID, slow release Gliclazide 60mg TID. In small pilot studies of 30 patient groups superiority of Sitagliptin at noon, morning and afternoon for Empagliflozin and Metformin, TID slow release Gliclazide were shown based on circadian rhythm. Two weeks later addition of Metronidazole, Bismuth and Doxycycline for ten days suppressed the gut diabetogenic flora. A1C below 6, 5.5 and 5 were reacted by omitting 1, 2 or 3 gliclazide after each 3 months cycle.
Results
Ninety-four and 87% attained HBA1C under 6.5 and 6 within 3 to six months. These values remained for a mean of 24 months (range 6-78). At least 23% i.e. 14490 patients could discontinue their medication with a relapse rate of 32%. Less than 0.2% needed additional insulin. Four to eight percent did not respond enough and were regarded as special refractory subgroups due to MODY, Glut mutations or downstream genes. Neither response nor side effects were correlated with duration of disease, previous drug exposure, A1C at begin, inter current disease, age, sex… Thousands of patients were lost from follow up above 36 months but results remain reliable for the rest.
Discussion
We have shown that type II diabetes is a potentially curable disease with an acceptable percentage. This treatment may become the gold standard of type II diabetes at any stage as it is easy with good compliance, abolishes additional insulin, very cost effective, very low need for surveillance and uniformly effective. It covers all theoretical and empirical sorts of resistance. All patients maintain on 2 tablets every 8h. Gliclazide 60 1 1 1 (Empagliflozin + Metformin) 500/12.5 1 1 Sitapliptin 100 1

Diabetes and self-harm: a struggle beyond the surface

Yesmine Elloumi[1], Fedia Boubaker[1], Houcem Elomma Mrabet[1], Najoua Lassoued[1], Baha Zantour[1], Alaya Wafa[1] & Habib Sfar[1]
[1]Taher Sfar University Hospital, Mahdia, Tunisia

Background
The psychological burden of diabetes remains largely underestimated. Often perceived as an intimate tragedy, it can manifest outwardly through self-destructive behaviors such as self-harm. Diabetic patients are consequently at a heightened risk of mortality associated with severe psychiatric disorders, including suicide. Early and tailored intervention is essential to mitigate these adverse outcomes.
Case Reports
Case 1: A 50-year-old woman with a long-standing history of type 1 diabetes since childhood, managed with insulin therapy, experienced multiple hospitalizations due to poorly controlled diabetes. Her medical history included a lacunar ischemic stroke and hypertension. During her hospital stays, she presented with polymorphic skin lesions, including excoriations, linear scratches, and occasionally lichenified ulcers, predominantly on her arms and legs. These lesions were attributed to intense pruritus. A skin biopsy excluded cutaneous leishmaniasis. The lesions were suspected to be exacerbated during episodes of metabolic decompensation. Following the exclusion of systemic causes, a diagnosis of psychogenic pruritus was established. Case 2: A 48-year-old woman with a two-year history of type 2 diabetes and hypertension presented with a four-month history of skin lesions localized to her legs, characterized by ulcers and linear scratch marks. A skin biopsy revealed no abnormalities. The patient reported experiencing severe itching episodes, particularly during acute metabolic decompensations.
Conclusion
Psychiatric disorders are significantly more prevalent among diabetic patients compared to the general population. Routine screening for anxiety and depressive symptoms is imperative in this vulnerable group to ensure timely and effective management, thereby reducing their psychological and physical burden.

Incidence and survival of neuroendocrine neoplasia in the maltese islands – a population-based study

Jessica Mangion[1,2], Josanne Vassallo[1,2] & Mark Gruppetta[1,2]
[1]Department of Medicine, Faculty of Medicine and Surgery, University of Malta, Mater Dei Hospital, Msida, Malta; [2]Neuroendocrine Clinic, Department of Medicine, Mater Dei Hospital, Msida, Malta

Introduction
The global incidence of neuroendocrine neoplasms (NENs) is increasing worldwide, however most studies are based on cancer-registry data, with different data collection methods, making it difficult for cross-country comparisons. Our study aims to analyze the incidence and survival of NENs in a well-defined population of the Maltese islands based on histological and radiological data.
Methods
A retrospective analysis of patients diagnosed histologically or radiologically with NEN at Mater Dei Hospital, the only central national service hospital in Malta, between 1st January 2015 and 31st December 2020, was performed. Detailed clinical, histopathological and radiological data was obtained. Patients were followed up till 31st December 2024 or death, whichever came first. Age- and sex-adjusted standardized incidence rates (SIRs), prevalence and mortality rates were calculated.
Results
A total of 435 patients were identified, of which 237 (54.48%) were males. The median age at diagnosis was 68 years (IQR 59-74). The overall age-adjusted SIR was 8.78/100,000/year, with a male-to-female ratio of 1.2:1. The age-adjusted SIR of bronchopulmonary NEN (BP-NEN) was 2.77/100,000/year whilst that of gastro-enteropancreatic NEN (GEP-NEN) was 4.02/100,000/year. The 6-year limited duration prevalence rate was 43.7/100,000. The most frequent location of GEP-NEN was the pancreas (11.26%) followed by the appendix (7.13%) and rectum (5.98%) whilst the duodenum (2.76%) and the oesophagus were the less frequent (0.69%). Well-differentiated Grade 1 GEP-NEN prevailed at 63.74%, followed by Grade 2 at 8.24% and Grade 3 at 7.69%. Poorly differentiated neuroendocrine carcinoma was found in 7.14% of the patients. Most tumours were localized (57.59%) with 28.02% having disseminated disease at presentation. Distant metastasis were most commonly observed in NEN of the jejunum and ileum (27.45%) and the rectum (21.57%). Two hundred and forty-five patients (56.32%) passed away during the study period. The standard mortality ratio (SMR) of all NEN was 4.59 (95% CI 4.02-5.17). A higher mortality was observed in BP-NEN, which had an SMR of 6.52 (95% CI 5.35-7.68), compared to GEP-NEN, which had an SMR of 3.68 (95% CI 2.3-4.56). Univariate analysis revealed a statistically significant association between mortality and male gender (p 0.001), age at diagnosis ($P < 0.001$), primary site ($P < 0.001$), grade ($P < 0.001$), stage ($P < 0.001$) and Ki67 ($P < 0.001$).

Conclusion
This is the first study reporting the incidence, prevalence and survival rates of NEN in the Maltese Islands. Our findings suggest that GEP-NEN and BP-NEN incidence and survival in the Maltese Islands is comparable to that observed in other countries.

V804M RET mutation screening and familial medullary thyroid carcinoma in the Maltese Islands

Jessica Mangion[1,2], Miriam Giordano Imbroll[1,2] & Mark Gruppetta[1,2]
[1]Department of Medicine, Faculty of Medicine and Surgery, University of Malta, Mater Dei Hospital, Msida, Malta; [2]Neuroendocrine Clinic, Department of Medicine, Mater Dei Hospital, Msida, Malta

Introduction
Multiple Endocrine Neoplasia Type 2 is linked with activated germline mutations of the RET proto-oncogene, one of which, Val804Met (V804M) mutation has been classified as moderate risk to develop medullary thyroid carcinoma (MTC) according to the American Thyroid Association. Our study aims to investigate a cohort of Maltese patients carriers for V804M mutation and compare their clinical, biochemical and histopathological characteristics.
Methods
Genetic screening of relatives of the index case, who was diagnosed with homozygous V804M mutation in the RET gene in 2022, was done in Malta, between November 2022 and December 2024. Detailed clinical, radiological and histopathological data was obtained for each patient who had the mutation.
Results
A total of 57 patients were screened, of which 31 (54.4%) were positive for V804M mutation. Eighteen patients (58.1%) were males and only 1 patient (index's case brother) was homozygous for this mutation. The median age at diagnosis was 44 years (IQR 26.0-52.5). Five (16.1%) were 1st degree relatives to the index case, 11 (35.5%) were 2nd degree, 12 (38.7%) were 3rd degree and 2 (6.5%) were 4th degree. The index case had a co-existing somatotropinoma. No patients had phaeochromocytoma, hyperparathyroidism, Hirschsprung disease or cutaneous lichen amyloidosis throughout the study period. The median initial calcitonin was 5pg/ml (IQR 3.7-17.0). The highest initial calcitonin was observed in the index case and her brother, (4300pg/ml and 403pg/ml, respectively). Thirteen (42.0%) patients underwent surgery. Eleven (84.6%) had MTC present on histological analysis, whilst one had only C-cell hyperplasia and another had neither MTC nor C-cell hyperplasia. One of the patients with MTC had an undetectable pre-operative calcitonin level. The median size of the largest focus of MTC was 7mm (IQR 2.5-12.5). Two patients (15.4%) had concurrent papillary thyroid carcinoma. Distant metastasis was only observed in the index case, whilst lymph node metastasis was present in 2 patients (30.8%). Post-operative calcitonin remained elevated in 3 cases at 525pg/ml, 150pg/ml and 10ng/ml, respectively. None received adjuvant radiotherapy or chemotherapy. No patient died during the study period.
Conclusion
This is the first study evaluating carriers of V804M RET mutation in the Maltese Islands. Despite most studies recommend total thyroidectomy based on elevated calcitonin level in carriers, our study suggests that MTC can be present even at undetectable calcitonin levels. However, further screening of the relatives of the index case is still undergoing, which can enhance our understanding of the natural history of this condition.

Usefulness of the braf gene study in the evaluation of the thyroid nodule

Elena Martínez Silla[1], Raúl Rodríguez Juárez[1], Antonia García Martín[1], Mercedes Caba Molina[2] & Pablo José López-Ibarra Lozano[1]
[1]Hospital Universitario Clínico San Cecilio, Endocrinología y Nutrición, Granada, Spain; [2]Hospital Universitario Clínico San Cecilio, Anatomía Patológica, Granada, Spain

Introduction
Fine needle aspiration puncture (FNA) is the method of choice for the study of the thyroid nodule. However, its diagnostic yield decreases in case of indeterminate cytological results. Our aim was to evaluate the usefulness of molecular study of the BRAF gene in thyroid nodule aspirate samples in deciding the therapeutic attitude.
Material and Methods
Retrospective observational study of 51 patients evaluated at the Thyroid Nodule consultation of the Hospital Universitario Clínico San Cecilio who underwent FNA and BRAF gene sequencing on thyroid nodule between October 2019 and February 2024.
Results
Thirty-five females and 16 males were studied. The mean age of the sample was 52.8 $\pm$ 12.5 years. The cytological results of FNA of the thyroid nodule according to the Bethesda system were: 66.7% BIII, 11.8% BV, 9.8% BIV and 3.9% BII, 7.9% BI. BRAF V600E mutation was present in 17.6% of the sample. 29 patients had undergone surgery and 18 of them had papillary thyroid carcinoma on pathology. In the intervened patients, total thyroidectomy was more frequent than haemithyroidectomy in those patients with mutated BRAF gene ($P = 0.001$) and pathological anatomy of malignancy more frequent in those with BRAF gene mutation ($P = 0.026$). In patients with Bethesda III and BRAF gene mutation, the decision to perform total thyroidectomy compared to haemithyroidectomy was more frequent ($P = 0.006$) as well as an anatomopathological diagnosis of papillary thyroid carcinoma of the surgical specimen compared to benignity ($P = 0.055$).
Conclusions
The study of mutations in the BRAF gene is useful for the therapeutic decision of thyroid nodules with indeterminate cytological results, as well as to determine the extent of thyroid surgery.

Diffuse large B-cell lymphoma leading to polyendocrine involvement (pituitary, adrenal, and thyroid)

Morgane Mauger[1], Patricia Vaduva[1] & Agathe GUENEGO[1]
[1]University Hospital of Rennes, Rennes, France

Introduction
Diffuse large cell B lymphoma (DLBCL) is the most common histological subtype of non-Hodgkin's lymphoma (30%). Its clinical presentation is highly heterogeneous and endocrine involvement is a rare manifestation. Non-Hodgkin's lymphomas account for 3% of intracranial tumours. DLBCL is an even rarer cause of metastatic pituitary infiltration (<0.5%).
Observation
We report the case of a 54-year-old patient hospitalized for altered general condition and B symptoms. The initial work-up revealed low TSH and low T4, prompting further assessment of the other pituitary hormones, confirming the presence of thyrotropic, corticotropic and somatotropic insufficiencies, disconnection hyperprolactinaemia, and diabetes insipidus. Pituitary MRI was consistent with hypophysitis. The infectious and autoimmune work-up was unremarkable. PET-18FDG revealed pathological hypermetabolism of the left adrenal gland, pituitary gland, thyroid, subdiaphragmatic lymph nodes and subcutaneous nodules. The adrenal lesion was suspicious on contrast-enhanced CT, with plasma metanephrine levels normal. Thyroid ultrasound suggested thyroiditis with weakly positive anti-TPO antibodies. High LDH levels (936 IU/l, normal < 225), rapidly worsening pancytopenia and splenomegaly on ultrasound raised suspicion of haemopathy. A biopsy of the subcutaneous nodules finally led to the diagnosis of DLBCL. Corticotropic, thyrotropic insufficiencies and diabetes insipidus were managed with appropriate hormonal replacement therapy, and R-CHOP chemotherapy was rapidly initiated. After four treatment cycles, follow-up pituitary MRI and FDG-PET scan showed a complete morphometabolic regression of adrenal, pituitary, subcutaneous, radicular, lymph node, and bone involvement. The loss of hypersignal of the posterior pituitary gland persisted on MRI. Hormone replacement therapy remained necessary.
Conclusion
A haemopathy should be sought in cases of suspected secondary hypophysitis. The literature reports very few cases of DLBCL with synchronous involvement of several endocrine glands, and their prevalence is yet to be determined. A multidisciplinary collaboration between endocrinologists, haematologists and oncologists is essential to optimise patient management.

JOINT2029

Bone metastases revealing a follicular carcinoma of the thyroid

Rachida Bouattay[1], Sabrina Farhani[1], May Ferjani[1], Khaled Harrathi[1] & Jamel Koubaa[1]

[1]ENT and Head and Neck Department, University Hospital of Fattouma Bourguiba, Monastir, Tunisia

Introduction
Follicular thyroid carcinoma represents 5 to 8% of malignant thyroid tumors and 10 to 20% of differentiated thyroid cancers. It is characterized by the frequency of visceral metastases, particularly bone metastases.
Aim
The aim of our work is to study the clinical aspects, and the therapeutic and evolutionary modalities of metastatic vesicular carcinomas of the thyroid, through 4 observations with review of the literature.
Material and Methods
We report 4 cases of bone metastases revealing follicular thyroid carcinoma collected from a total of 30 patients treated for follicular thyroid carcinoma treated in the ENT and CCF department of over a period of 24 years.
Results
The average age was 51 years (35–72 years) with a female predominance (three women and one man). The reason for consultation was bone pain in 3 cases, a pathological fracture in one case. The ENT examination showed anterior cervical base swelling in 3 cases and was normal in one case. The cervical ultrasound showed thyroid nodules in all cases with malignancy criteria in 2 cases. Bone metastases were lumbar in three cases and femoral in one case, all confirmed by bone biopsy. The diagnosis of associated pulmonary metastasis was made by bronchial biopsy in one case. Treatment was based on total thyroidectomy associated with central lymph node dissection. The anatomopathological examination confirmed the diagnosis of follicular carcinoma in all cases. All patients underwent IRA therapy and were put on hormone-restricting therapy. Radiochemotherapy was indicated in the patient with bone and pulmonary metastases. The outcome was favorable in two cases; one patient was lost to follow-up and one patient died.
Conclusion
The presence of metastases in association with follicular thyroid cancer worsens the prognosis. Bone localization is the majority. Its management is multidisciplinary. Treatment consists of total thyroidectomy with excision of the metastatic lesion, if possible. Depending on the functional impact of the metastases, treatment will be supplemented by the administration of radioactive iodine and/or external radiotherapy. Hormonal inhibitory treatment is systematic in all cases.

Autoimmune endocrinopathies associated with the use of immune checkpoint inhibitors: a clinical case of a combination of primary hypothyroidism due to destructive thyroiditis and diabetes mellitus

Laura Ebanoidze[1], Mariia Berlovich[1], Elena Kaletnik[1], Ekaterina Pigarova[1], Larisa Dzeranova[1], Elena Przhiyalkovskaya[1] & Agunda Dzagakhova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Immune checkpoint inhibitors (ICIs) have transformed cancer treatment by enhancing the immune system's ability to recognize and destroy cancer cells. These drugs target regulatory pathways in T-cells, particularly programmed cell death protein 1 (PD-1) and its ligand PD-L1, which can allow cancer cells to evade immune detection. While ICIs have demonstrated significant success in improving survival rates across various cancers, their use is often associated with autoimmune adverse events (AIAEs). Among these, endocrinopathies are particularly common, as the heightened immune response can sometimes attack healthy endocrine organs, leading to conditions such as thyroiditis and diabetes mellitus.
Materials and Methods
In 2018, at the age of 33, Patient T. underwent surgical excision of melanoma in the right subclavian region. Disease progression led to further surgeries in May 2021, including right-sided axillary-subscapular-subclavian lymphadenectomy, left kidney resection, and liver biopsy. In December 2022, the patient was prescribed prolgolimab, a human monoclonal antibody that binds specifically to PD-1, inhibiting its interaction with PD-L1 and PD-L2 to prevent tumor cells from evading the immune system. In January 2023, while undergoing oncoimmunotherapy, the patient reported symptoms of severe thirst, frequent urination, and hyperglycemia, with initial blood glucose levels reaching 40.9mmol/l. He was promptly hospitalized in intensive care, where a diagnosis of mixed-genesis ketoacidosis with cerebral edema was made. Basal-bolus insulin therapy was initiated to manage blood glucose levels. Further evaluation at the National Medical Research Center of Endocrinology in June 2023 revealed significant endocrine findings: C-peptide levels at 7.0pmol/l (reference range: 100–1100), insulin autoantibodies at 3.4IU/mL (0–10), GAD autoantibodies at 0.1U/mL (0–10), and pancreatic beta cell autoantibodies at 0.35 (0–1). Insulin therapy was adjusted to optimize glycemic control, and the patient's glucose levels were stabilized within individually targeted ranges. Approximately one year after the diabetes mellitus diagnosis, and following three courses of immune checkpoint therapy (nivolumab + ipilimumab), the patient developed destructive thyroiditis in its hypothyroid phase. Laboratory values indicated TSH at 56.9mU/l (0.27–4.2), free T4 at 2.71pmol/l (12–22), and free T3 at 1.65pmol/l (3.1–6.8). Levothyroxine sodium was initiated at 75mg/day, with gradual titration to 112.5mg/day to achieve targeted hypothyroidism compensation.
Results
This case highlights the complex immune response triggered by ICIs, as evidenced by the sequential onset of two significant autoimmune endocrinopathies-diabetes mellitus and thyroiditis. The varied timing of these events underscores the need for diligent monitoring for endocrine disorders throughout different phases of ICI therapy.

Hyperprolactinemia and cancer risk: a swedish population-based cohort study

Christos Himonakos[1,2], Louise Emilsson[3,4,5], Sophie Bensing[1,6] & Katarina Berinder[1,6]
[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [2]Karlstad Central Hospital, Department of Internal Medicin, Center for Endocrinology and Diabetes, Karlstad, Sweden; [3]Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden; [4]Nysäter Health Care Center & Centre for Clinical Research, County Council of Värmland, Sweden; [5]Institute of Health and Society, University of Oslo, Department of General Practice & General Practice Research Unit (AFE), Oslo, Norway; [6]Karolinska University Hospital, Department of Endocrinology, Stockholm, Sweden

Background
Concerns about the potential link between hyperprolactinemia (HPL) and cancer primarily arise from prolactin's (PRL) role in promoting cell proliferation and the increased expression of PRL receptors in various cancer types. However, only a few studies have examined cancer risk in patients with HPL.
Purpose
To investigate cancer risk in a nation-wide cohort of patients with a diagnosis of HPL, with special emphasis on breast cancer.
Methods
In a Swedish population-based cohort study, we used nationwide registries to identify 3837 patients with HPL treated with dopamine agonists (DA) diagnosed between 2006 and 2019, along with 38370 controls matched by age, sex and county of residence. Cancer outcomes (overall and specific types) as registered in the Swedish Cancer Registry, were analyzed using Cox regression, internally stratified by the matching variables and additionally adjusted for diabetes mellitus, obesity, smoking, alcohol overconsumption, hormone replacement therapy and educational level to estimate adjusted hazard ratios (aHRs).
Results
During a median follow-up time of 6.1 years (interquartile range [IQR] 3.4-9.6), 168 (4.6%) new cases of cancer were identified in patients with HPL and 1608 (4.4%) in the control group (aHR 1.05 [95% CI: 0.89-1.23]). Twenty-eight (0.7%) patients (all women) in the HPL group and 267 (0.7%) in the control group developed breast cancer, (aHR 1.02 [95% CI: 0.68-1.51]). Similarly, there was no increased risk of any other site-specific cancer.
Conclusions
In this nation-wide cohort study of patients with DA-treated HPL, no increased risk of overall cancer, breast cancer or other site-specific malignancies was observed.

Cowden syndrome: a case report

Mariem Souissi[1], Houcem Elomma Mrabet[1], Oumaima Dimassi[1], Alaya Wafa[1] & Sfar Mohamed Habib[1]

[1]Taher Sfar University Hospital, Endocrinology-Diabetology and internal Medicine Department, Mahdia, Tunisia

Cowden syndrome, also known as multiple hamartoma syndrome, is a rare condition with an autosomal dominant inheritance pattern, characterized by cutaneous and mucosal lesions associated with various neoplasms.
Case Presentation
This is the case of a 47-year-old woman who was admitted to our Endocrinology department in February 2024 for the management of profound hypothyroidism (FT4 = 0, TSH > 51) associated with hypocalcemia (1.6 mmol/l) resulting from the discontinuation of her replacement therapy. In her personal medical history, the patient underwent a total thyroidectomy for minimally invasive carcinoma in 2008, complicated by permanent hypoparathyroidism, and has a history of fibrocystic breast disease. On examination, macrocephaly was noted, along with cutaneous and mucosal lesions: about ten acral palmoplantar keratosis lesions and gingival papules. Cowden syndrome was therefore suspected, and further evaluation revealed a suspicious nodule in the right breast, colonic polyposis, nodular gastritis, duodenal polyposis, and endometrial thickening.
Discussion
The association of cutaneous and mucosal lesions with benign breast disease and/or thyroid, breast, and uterine neoplasms should lead clinicians to suspect Cowden syndrome, which requires a careful examination and comprehensive lesion evaluation. Diagnosis is based on the presence of major and minor pathognomonic criteria. Management is multidisciplinary, and lifelong surveillance is necessary.
Conclusion
Early diagnosis of Cowden syndrome is crucial. Genetic counseling and family investigation are mandatory as part of the management process.

Neuroendocrine tumors in association with other primary neoplasms

Andreea Anne-Marie Brînzan[1,2], Burcea Iulia-Florentina[1,2], Dobre Ramona[1,2] & Catalina Poiana[1,2]
[1]C.I Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
Neuroendocrine tumors (NETs) mostly affect the gastro-entero-pancreatic system and then the lungs. One significant clinical phenomenon observed in patients with NETs is the increased prevalence of synchronous or metachronous secondary primary neoplasms (SPMs), mainly gastrointestinal, raising questions about whether these occurrences are coincidental or reflect underlying genetic factors.
Materials and Methods
A retrospective observational study was conducted on a cohort of 93 patients diagnosed with neuroendocrine neoplasms in our department between January 2018 and January 2025. Data including demographics, histopathological and immunohistochemical profiles, imaging findings, and treatment details were collected from medical records.
Results
Twelve patients were diagnosed with SPMs and there were 14 distinct types of neoplasms identified. Among these, 50% of SPMs were diagnosed prior to the detection of NETs. There were 7 males (58.3%), 5 females (41.7%) and the mean age was 58.8 years. The most frequent SPM sites included the biliary (3 cases) and genitourinary (3 cases) tracts. There were three patients with multiple endocrine neoplasia type 1 (MEN1) syndrome, genetically confirmed. A unique case of MEN1 syndrome was identified, involving multiple malignancies: papillary thyroid carcinoma, tonsillar squamous cell carcinoma, a pancreatic grade 1 NET, an atypical thymic carcinoid and a lung adenocarcinoma. This case highlighted a large heterozygous deletion in the MEN1 gene (exons 3–8), suggesting a possible pathogenic variant contributing to the disease's course. The impact of a second neoplasm on the disease progression was less significant compared to the influence of NETs.
Conclusions
Patients with NETs exhibit an incresed risk of developing SPM, with potential genetic syndromes like MEN1 playing a pivotal role in predisposing individuals to multiple neoplasms. Furthermore, the diagnosis of SPMs both prior to and following NET detection emphasizes the importance of vigilant, ongoing surveillance in this patient population. The progression of NETs rather than SPMs was the dominant determinant of patient outcomes, suggesting a unique dynamic that warrants further investigation.

Case series: ^{131}I-MIBG treatment in pheochromocytoma and paraganglioma – insights from our experience

Myriam Medjaher[1], Souleimane Meza[1], Sofiane Rahal[1] & Moussa Nacer Khodja[1]
[1]Central Hospital of the Army, Algiers, Algeria

Introduction
Pheochromocytomas (PCC) and paragangliomas (PGL) are neuroendocrine tumors arising from chromaffin cells, often presenting with catecholamine hypersecretion. For metastatic or unresectable cases, ^{131}I-metaiodobenzylguanidine (^{131}I-MIBG) therapy offers a targeted radiopharmaceutical approach, delivering beta radiation. This case series explores the therapeutic role of ^{131}I-MIBG in different clinical settings from the experience of our department.
Methods
A retrospective analysis was conducted on five patients diagnosed with PCC or PGL and treated with ^{131}I-MIBG at our institution. The study includes cases where ^{131}I-MIBG was utilized as primary therapy, neoadjuvant treatment, or for metastatic disease. Clinical, biochemical, imaging, and treatment outcome data were analyzed.
Case Summaries
- **Case 1:** A 29-year-old female with metastatic pelvic PGL received four cycles of ^{131}I-MIBG (28 GBq), leading to tumor shrinkage and enabling surgical resection. No complications were noted.
- **Case 2:** A 41-year-old female with bilateral PCC and pelvic metastasis underwent surgery but had residual disease. Two cycles of ^{131}I-MIBG (11.1 GBq) achieved complete biochemical and morphological response.
- **Case 3:** A 55-year-old female with recurrent para-aortic PGL received one adjuvant ^{131}I-MIBG cycle (5.5 GBq) following multiple surgeries. A three-year follow-up showed normal urinary normetanephrines with no reported side effects.
- **Case 4:** A 50-year-old female with inoperable mediastinal and retroperitoneal PGL underwent two cycles of ^{131}I-MIBG (14.8 GBq), achieving biochemical improvement and stable disease. A third cycle was planned. Side effects were mild (nausea, fatigue).
- **Case 5:** A 48-year-old male with metastatic PCC (liver and bone) received one cycle of ^{131}I-MIBG (7.4 GBq) post-radiotherapy. He developed pancytopenia five weeks later but recovered.

Results
- **Tumor Response:** ^{131}I-MIBG therapy reduced tumor size in some cases, aiding surgical resection, and stabilized disease in others.
- **Biochemical Outcomes:** Significant decreases in urinary catecholamines and metanephrines were observed, with normalization in select cases.
- **Symptom Control & Safety:** Symptoms improved, with manageable side effects (nausea, fatigue, myelosuppression). No hypertensive crises occurred.

Discussion
This case series illustrates the versatility of ^{131}I-MIBG therapy, demonstrating its role in neoadjuvant, primary, and palliative settings. Tumor downstaging, biochemical response, and symptom control were achieved. A multidisciplinary approach is important in optimizing treatment strategies. Further research is could refine protocols and improve patient selection.
Conclusion
^{131}I-MIBG therapy remains an effective treatment for PCC and PGL, offering tumor control, biochemical improvement, and symptomatic relief. This series highlights its use beyond metastatic disease, particularly in neoadjuvant and primary treatment settings.

A case of a 5.5-years-old girl with clitoromegaly, café-au-lait spots and a pathogenic variant in NF1 gene inherited from the mother

Silvia Andonova[1], Tihomir Todorov[1], Zdravka Todorova[2,3], Diana Hristova[3,4] & Albena Todorova[1,5]
[1]GMDL "Genica" and IMDL "Genome Center Bulgaria", Sofia, Bulgaria; [2]Department of Pediatric Endocrinology, Specialized Hospital for Active Treatment of Pediatric Diseases, Medical University-Sofia, Sofia, Bulgaria; [3]Medical Faculty, Medical University-Sofia, Sofia, Bulgaria; [4]UHOG "Maichin dom", Medical University-Sofia, Sofia, Bulgaria; [5]Department of Medical Chemistry and Biochemistry, Medical University-Sofia, Sofia, Bulgaria

Background
Clitoromegaly in infant girls is usually related with conditions from the Disorders of sexual development (DSD) spectrum but can also be an unusual manifestation of other diseases such as Neurofibromatosis type 1 (NF1). NF1 is a rare

autosomal-dominant disorder caused by heterozygous mutations in *NF1* gene; 50% of the cases are de novo. Phenotype includes café-au-lait spots, axillary and/or inguinal freckling, increased susceptibility for development of benign/-malignant tumors in peripheral nerves, etc., but in sporadic cases a clitoromegaly was also reported.
Case presentation
The index patient is a 5.5-years-old girl referred for genetic testing due to a progressive enlargement of the clitoris during the last year. The child was assigned as a female with no other signs of virilization but with growth delay and few café-au-lait spots from the birth. Retrospectively, a positive family history for hyperpigmented café-au-lait spots and short stature was announced in mother and maternal grandfather with no other severe presentations of Neurofibromatosis. The laboratory tests in proband revealed normal thyroid function, normal levels of androgens and gonadotropins and 46, XX karyotype. DNA from venous blood was extracted from the patient and her parents and Whole exome sequencing (WES) was performed with targeted analysis of genes associated with DSD and NF. A heterozygous pathogenic variant NF1:c.7348C>T, p.Arg2450Ter was identified in the patient; the subsequent Sanger sequencing revealed the maternal origin of the mutation. Additionally, a prenatal diagnosis was advised in the current pregnancy in the family and a heterozygous mutation was detected in the male fetus. However, family decided to continue with the pregnancy and a boy was born at term without complications. Both children are currently on close monitoring from skilled pediatric endocrinologist in order to pursue the clinical presentation and effective treatment to be provided on time.
Conclusions
The use of advanced genetic tests might be very helpful in cases with complex presentation. Determination of correct genotype-phenotype correlations is of high importance in precise diagnosis, better follow-up and clinical management of such heterogeneous conditions as NF1 with non-typical clinical features.

A unique case of pheochromocytoma crisis leading to hypoxic cardiac arrest requiring veno-arterial-venous extracorporeal membrane oxygenation (ECMO) in a postpartum patient

Arshia Beigi[1], Shadan Ashrafi[2] & Benjamin Schroeder[1]
[1]University of British Columbia, Department of Medicine, Division of Endocrinology, Vancouver, Canada; [2]University of British Columbia, Department of Medicine, Vancouver, Canada

Background
Large-volume hemoptysis due to a hypertensive crisis is a rare initial presentation of pheochromocytoma. We report a case of a postpartum patient who developed severe hypoxic respiratory failure necessitating ECMO support.
Clinical Case
A 34-year-old G2P2 woman presented to the emergency department (ED) on postpartum day 1 after an uncomplicated vaginal delivery with a one-day history of nausea, vomiting, headache and chest tightness. She had experienced similar but less severe symptoms following her first delivery three years earlier, which resolved within a few months. She was asymptomatic during her second pregnancy. In the ED, her systolic blood pressure (SBP) reached 200 mmHg. A CT pulmonary angiogram, ordered to assess for pulmonary embolism, incidentally revealed a large 18 cm left adrenal mass, highly suggestive of pheochromocytoma. Upon admission to ICU, she was started on doxazosin and IV phentolamine infusion. A 24-hour urine collection for metanephrines and catecholamines was sent. Labetalol was briefly introduced for persistent tachycardia but was discontinued due to extreme blood pressure fluctuations, with SBP exceeding 200 mmHg followed by profound hypotension. She subsequently developed hemoptysis and pulmonary edema, necessitating intubation. Worsening hypoxia and hypotension led to a pulseless electrical activity (PEA) arrest. Following resuscitation and return of spontaneous circulation (ROSC), VV-ECMO was planned for respiratory failure. However, she developed a narrow-complex SVT, triggering another PEA arrest. After ROSC, she was transitioned to V-A-V ECMO due to concern for catecholamine-induced arrhythmias. Doxazosin was increased to 8 mg BID alongside continued phentolamine infusion. Verapamil was added to manage her heart rate. By day 3, her hemodynamics stabilized, allowing for extubation and ECMO decannulation. Her 24-hour urine studies revealed norepinephrine 10,670 nmol/day, epinephrine 7,216 nmol/day, normetanephrine 3,153 nmol/day, and metanephrine 4,296 nmol/day. The remainder of her hospitalization was uneventful. She was discharged on doxazosin 12 mg BID and propranolol 20 mg QID. Adrenalectomy was deferred until six weeks postpartum to allow uterine involution and vascular stabilization. She underwent an uncomplicated laparoscopic left adrenalectomy. She returned five days postoperatively with pain, nausea, and vomiting, and imaging revealed a subtotal infarction of the left kidney. Despite this, renal function remained intact, and postoperative urine catecholamines and metanephrines normalized.
Conclusion
Severe hypoxemic respiratory failure requiring ECMO due to hemoptysis and pulmonary edema is a rare presentation of pheochromocytoma. This case highlights a rare pheochromocytoma crisis in which ECMO was required for respiratory failure rather than the more frequently reported cardiogenic shock.

Higher incidence of fatigue in thyroid cancer survivors transitioning to primary care compared to other cancer survivors

Fatima Imran[1], Syed Ahmad[1], Murali Rajaraman[1], Syed Ali Imran[1] & Robin Urquhart[1]
[1]Dalhousie University, Halifax, Canada

Background
Despite the high incidence of differentiated thyroid cancer (DTC), the overall mortality has remained low. Combined with a younger age at diagnosis, thyroid cancer prevalence is higher than expected necessitating a focus on survivorship issues, lifelong surveillance and transitioning low-risk DTC survivors to primary care. A recent pan-Canadian study showed that survivors of other cancers consistently report several unmet physical and psychosocial needs. However, the specific needs of DTC survivors remain unknown.
Objectives
1) To describe the self-reported physical, emotional, practical and informational needs of low-risk DTC survivors in Nova Scotia, Canada, during the transition period to primary care; and 2) To compare the physical, emotional, practical and informational needs of low-risk DTC survivors with those of melanoma, breast, colorectal, hematological and prostate cancer survivors.
Methods
A cross-sectional survey using the 83 item "Cancer Transition Survey" was conducted based on the national Experiences of Cancer Patients in Transition Study. The survey was administered to adult patients with low-risk DTC who have been discharged, or were ready for discharge, from specialist to primary care. Survey data from DTC survivors were compared with data from other cancer survivors previously surveyed as part of the national study.
Results
A total of 205 patients responded, with a response rate of 54.6%. Most respondents in the DTC sample were female (81.2%), more than half were in the 55-to 74-year-old age category. All patients had total thyroidectomy +/- I-131 therapy and were prescribed thyroid replacement therapy targeting TSH in a normal range. The most commonly reported post-treatment needs were fatigue (81.3%), anxiety/fear of recurrence (69.5%) and depression/low mood (46.3%). When compared with non-thyroid cancer survivors, DTC survivors reported higher rates of fatigue (81.3% vs. 64.3%, p-value < 0.001). Otherwise, supportive care needs of DTC survivors were similar to those of non-thyroid cancer survivors.
Conclusion
Both DTC survivors and other cancer survivors share similar supportive care needs. While fatigue is common across all cancer survivors, we found that post-treatment fatigue is significantly more prevalent in DTC survivors.

Impact of adjuvant mitotane on long-term outcomes in patients at high risk of adrenocortical carcinoma recurrence

Karla Čikeš[1], Karin Zibar Tomšić[2], Tanja Skoric Polovina[2], Mirsala Solak[2] & Darko Kastelan[2]
[1]General hospital "Dr. Ivo Pedišić" Sisak, Sisak, Croatia; [2]University Hospital Center Zagreb, Zagreb, Croatia

Introduction
Mitotane has been considered a mainstay adjuvant treatment for patients at high risk of adrenocortical carcinoma (ACC) recurrence. However, the level of evidence is graded as low to moderate, as this recommendation is based on the results of retrospective studies. The present study aimed to analyse the long-term outcomes of patients with ACC (ENSAT stage I-III, Ki-67 > 10%) based on whether they were treated with mitotane in the adjuvant setting.

Materials and Methods
This retrospective, single-center study included 34 patients diagnosed with ACC who underwent R0 surgery. Postoperatively, 26 patients received adjuvant mitotane for 24 months (IQR 20-35; M+ group). Of the 8 patients who did not receive mitotane (M- group), one stopped after one month due to liver toxicity, one refused treatment, and six underwent surgery in a non-expert center where adjuvant mitotane was not advised. The main study outcomes included recurrence-free survival (RFS), overall survival (OS) and disease specific survival (DSS).
Results
There were no significant differences between the groups in terms of age (44 years vs. 50 years; $P = 0.452$), tumor size (98 mm vs. 100 mm, $P = 0.791$) and hormonal hypersecretion (77% vs. 24%; $P = 0.067$). Patients in the M+ group had longer RFS compared to those in the M- group (133 $\pm$ 18 months vs. 52 $\pm$ 17 months; $P = 0.008$). In contrast, no differences were observed between the groups in OS (142 $\pm$ 17 months vs. 151 $\pm$ 29 months; $P = 0.941$) or DSS (180 $\pm$ 13 months vs. 167 $\pm$ 28 months; $P = 0.424$).
Conclusion
Adjuvant mitotane is associated with a significant improvement in RFS in patients at high risk of ACC recurrence. However, no significant impact was observed on OS or DSS.

Pubertal arrest, polydipsia, polyuria, headaches and diplopia in a 13 year old girl

Maria Margarita Rossolatou[1], Eirini Dikaiakou[1], Evgenia Magkou[2], George Anagnostopoulos[3], SOFIA LEKA-EMIRI[1], Maria Nikita[2], Agelina Sfetsiori[2], Ioanna Kosteria[1], George Markogiannakis[4], Dimitrios Doganis[2] & Elpis Vlachopapadopoulou[1]
[1]Children's Hospital "P. & A. Kyriakou", Endocrinology-Growth and Development, Athens, Greece; [2]Children's Hospital "P. & A. Kyriakou", Oncology, Athens, Greece; [3]Children's Hospital P & A Kyriakou, Neurosurgery, ATHENS, Greece; [4]Children's Hospital "P. & A. Kyriakou", Neurosurgery, Athens, Greece

Introduction
Germinomas comprise 60 to 65 percent of all pediatric intracranial germ-cell tumors (GCTs). The two most frequent sites are the pineal gland and the suprasellar regions. In 5 to 15 percent of cases, patients present with tumors at both pineal and suprasellar locations, referred to as bifocal disease. Pineal tumors typically cause obstructive hydrocephalus, presenting with signs of increased intracranial pressure. Neuro-ophthalmologic abnormalities are present in half of the cases. Suprasellar GCTs most commonly present with hypothalamic/pituitary dysfunction.
Methods
Case presentation:A 13-year-old girl presented with diplopia and left eye esotropia accompanied by ptosis in the previous 20 hours. Past medical history was unremarkable until two years ago when she started suffering early morning vomiting. They reported lethargy, fatigue, polyuria, polydipsia, loss of appetite and weight loss of 7 kilograms for the previous 8 months. Additionally, her mother has noticed regression of breast tissue and pubic hair growth. The patient's family history is unremarkable.
Results
The results from her first clinical assessment are height 1.57m, weight 37kg, pulse 113/min, DBP/SBP 96/60mmHg, temperature 36^0C, GCS 15/15, meningitis signs negative, cerebellar exam normal, left eye esotropia with ptosis, anisocoria, central facial palsy. Tanner stage: Breast II, pubic hair II-III. Fundoscopy revealed bilateral optical nerve edema. An emergency CT-scan revealed hydrocephalus., while the MRI scan revealed hydrocephalus and two space-occupying lesions, one in the region of the pineal gland and one in the pituitary stalk. Laboratory investigations showed increased levels of Na: 151mmol/l, dilute urine SG:1006, TSH: 0.995μIU/ml, fT4: 0.68ng/dl, (consistent with central hypothyroidism), undetectable gonadotropins, FSH: $<$0.3 mIU/ml, LH: $<$0.3mIU/ml, increased PRL: 1240 μIU/ml, very low E2: 5.21pg/ml, very low IGF1: 31.8 ng/ml, βHCG 7.02mU/ml, βHCG CSF: 2.3ng/ml, aFP 1,4ng/ml. Hormonal levels were consistent with the diagnosis of panhypopituitarism including arginine-vasopressin deficiency. Thus, treatment with hydrocortisone, desmopressin and levothyroxine was initiated. A ventriculoperitoneal shunt was implanted According to MRI findings and the following criteria: presence of diabetes insipidus, bifocal disease, positive CSF bHCG, the diagnosis of bifocal germinoma was established and chemotherapy treatment was initiated.
Conclusions
Pubertal arrest requires immediate attention and investigation for possible intracranial pathology (germinoma, craniopharyngioma, pilocytic astrocytoma) or histiocytosis. The suspicion is heightened when it is accompanied by headaches and polyuria, polydipsia

Bilateral and malignant reninoma - case presentation

Erik Bényei[1], Ádám Remport[2], Attila Patonai[2], Judit Tőke[1], László Piros[2], Anett Illés[1], Gertrúd Forika[3], Péter Nagy[3], János Kósa[1], Péter Lakatos[1] & Miklós Tóth[1]
[1]Semmelweis University, Faculty of Medicine, Department of Internal Medicine and Oncology, Budapest, Hungary; [2]Semmelweis University, Faculty of Medicine, Department of Surgery, Transplantation and Gastroenterology, Budapest, Hungary; [3]Semmelweis University, Faculty of Medicine, Department of Pathology and Experimental Cancer Research, Budapest, Hungary

Introduction
Reninoma, also referred to as juxtaglomerular cell tumour, is a renin-producing, typically benign lesion that originates from the juxtaglomerular cells of the afferent arterioles within the renal glomeruli. It represents a rare cause of secondary hyperaldosteronism. To date, approximately 200 cases of reninoma have been reported, with histologically confirmed metastasis described in only five patients.
Case report
This case study presents the medical history of a 26-year-old male patient with therapy-resistant hypertension and hypokalaemia, diagnosed with hyperreninemic hyperaldosteronism in 1972. Despite the extensive imagining procedures performed, the underlying cause was finally identified in 2004 when an abdominal CT scan revealed a right renal mass. The histopathological analysis of the removed tumour established the diagnosis of reninoma based on the positive immunohistochemistry results for renin and CD34 and the rhomboid-shaped renin proto-granulate crystals identified by electron microscopic examination. After 10 years of clinical remission, the patient exhibited signs of recurrent hyperreninemic hyperaldosteronism (2014). Histological investigation performed after the selective removal of a neoplastic lesion in the left kidney once again confirmed reninoma. The patient, who had developed chronic renal failure, underwent successful kidney transplantation after 2 years of regular haemodialysis (2017). Six years later, in 2023, a routine abdominal CT scan revealed solitary masses in the liver and the spleen. A biopsy of the hepatic lesion established the clinical and histological diagnosis of a bilateral, metastatic reninoma. Considering the excellent general condition of our patient at the age of 78, our multidisciplinary endocrine tumour board recommended an atypical hepatic resection and splenectomy, which was performed in 2024 (R0 resection). Following an uneventful postoperative course, based on follow-up imaging, the patient remains tumour-free. The exceptionally slow, multidecade-long progression and bilateral manifestation of the tumour suggest the etiological role of a genetic factor. Whole-exome sequencing identified a previously unreported mutation in the ARMC5 gene, whose role in the tumorigenesis remains to be clarified.
Conclusion
To our knowledge, this is the first reported case of malignant reninoma with bilateral manifestation. The bilateral presentation of our case strongly suggests the involvement of genetic factors, but the role of the identified germline **ARMC5**mutation in reninoma pathophysiology requires further investigation.

Delayed diagnosis of an optic chiasm germinoma in a child: clinical evolution and metabolic consequences

Orsolya Olah[1], Monica-Simina Mihuta[2,3,4], Cristina Ilies[5], Estera Boeriu[4] & Corina Paul[4]
[1]Ph. D. School "Victor Babes" University of Medicine and Pharmacy | Timisoara, Doctoral Training Program, Timişoara, Romania; [2]Center of Molecular Research in Nephrology and Vacular Disease, "Victor Babe" University Of Medicine and Pharmacy, Timişoara, Romania, Timişoara, Romania; [3]Dr. D Medical Center, Timişoara, Romania, Timişoara, Romania; [4]Department of Pediatrics, "Victor Babes" University of Medicine and Pharmacy | Timisoara, Timişoara, Romania; [5]Ph. D. School, "Victor Babes" University of Medicine and Pharmacy | Timisoara, Timişoara, Romania

Introduction
Germinomas are rare intracranial tumors that typically arise in the pineal or suprasellar regions, predominantly affecting adolescents and young adults, with a male predominance. When located in the suprasellar region, they may infiltrate the optic chiasm, leading to visual impairment and endocrine dysfunction. This case highlights the late diagnosis of an optic chiasm germinoma in a 9-year-old girl, emphasizing its late diagnosis and the subsequent development of hypothalamic obesity.
Case Report
A previously healthy 9-year-old girl presented with a rapid weight gain of 23 kg over eight months. Her eating habits had changed abruptly and significantly, and she developed polydipsia-polyuria syndrome (4L/day water intake), which remained unnoticed during the summer months. Upon starting school, a decline in visual acuity was observed. An optic nerve CT was performed, revealing bilateral optic nerve atrophy. Another month was lost investigating a possible neurodegenerative disease. Finally, a cerebral MRI scan revealed a tumor of the optic chiasm, initially suspected to be a craniopharyngioma. The tumor was located suprasellar, intrasellar, and retroclival, infiltrating the optic chiasm and protruding posteriorly into the third ventricle. A subtotal tumor resection was performed via a right pterional approach, and histopathological analysis confirmed the diagnosis of a germinoma, which was actually emerging from the optic chiasm. After surgery, the patient was initiated on hormone replacement therapy with hydrocortisone, levothyroxine, and desmopressin. Metabolically, she presented severe dyslipidemia (high LDL-cholesterol and triglycerides, and low HDL-cholesterol) and hepatic steatosis (as revealed by a FibroScan evaluation: CA*P* = 339 Db/m and E=3.8 kPa). She was subsequently administered chemotherapy and radiotherapy according to the SIOP CNS GCT II protocol. Her appetite remained voracious despite treatment, but her nutrition was successfully controlled with the involvement of her family. Six months after hydrocortisone substitution, the patient gradually developed a Cushingoid appearance, including truncal obesity, moon face, and extensive purple striae, but no hypertension, despite adequate weight management and controlled corticosteroid dosing. At present, the patient is in remission, with mild visual recovery, and remains under multidisciplinary follow-up involving oncology and endocrinology.
Conclusions
This case highlights the challenges in diagnosing optic chiasm germinomas, especially when visual impairment develops late. Hypothalamic obesity is a significant long-term complication following tumor resection and endocrine dysfunction. Recognizing early symptoms in pediatric patients with rapid weight gain and polydipsia can lead to timelier diagnosis and intervention, definitely improving clinical outcomes, especially visual loss.

Gastroenteropancreatic neuroendocrine tumours (GEP-NETs): clinical profile, treatment and 10-year survival

Fernando Vidal-Ostos De Lara[1], Jose Ignacio Busteros Moraza[2], Remedios Gomez Sanz[3], Bernard Theillac[4], Raquel Niddam Sanchez[1], Edinson Caviedes Sanchez[5], María Laura Villalobos Leon[5] & Concepción Blanco[1]
[1]Principe de Asturias University Hospital, Endocrinology and nutrition, Alcalá de Henares (Madrid)., Spain; [2]Principe de Asturias University Hospital, Pathological anatomy, Alcalá de Henares (Madrid)., Spain; [3]Principe de Asturias University Hospital, General surgery, Alcalá de Henares (Madrid)., Spain; [4]Principe de Asturias University Hospital, Nuclear medicine, Alcalá de Henares (Madrid)., Spain; [5]Principe de Asturias University Hospital, Oncology, Alcalá de Henares (Madrid)., Spain

Introduction
GEP-NETs are rare and heterogeneous neoplasms. Its prognosis depends on the histological grade as well as the extent of the tumour.
Material and Methods
We present a retrospective descriptive study based on patients diagnosed of GEP-NET and treated in a multidisciplinary unit in the last 10 years. Demographic data, location, tumour grade, metastases, treatment and survival were collected.
Results
From january 2014 to December 2024, 134 patients were diagnosed of GEP-NET. The annual incidence was 6.47 cases per 100,000 population and the adjusted prevalence was 0.052%. The mean age at diagnosis was 58±15 years, 51% were men and 49 % women. The most common origin was the pancreas (52%), followed by the jejunum-ileum (23%). At diagnosis 24% had distant metastases, most often located in the liver (44 %), peritoneum (25%) or multiple organs (22%). Most of them were sporadic and non-functional. Only 27 tumors were functional, most common insulinomas (11) and 10 had an inherited syndrome (9 MEN1 and 1 NF1). 66 % of patients underwent surgery for the primary tumour. The histological grade was G1 73%, G2 22% and G3 5%. 47 patients had tumour persistence and received somatostatin analogues (47), liver-directed therapy (11), systemic treatments such as everolimus (20), sunitinib (5), chemotherapy (7) and lutetium (12). During the follow up 26% of patients died. 74% were alive at the time of the last visit. The mean survival after diagnosing was 6 ± 5 years (median 5 years). At last visit 44% of patients had complete remission 2.4% partial response, 30.5% stable disease and 23% progression.
Conclusions
The incidence of GEP-NETs is higher than previous reports probably related to greater diagnostic resources. GEP-NETs have a relatively long survival even in those with metastases. Early diagnosis and multimodal treatment improve survival.

A rare case of chronic diarrhoea: medullary carcinoma of the thyroid

Connor S Brett[1], Matilda G W Brown[2], Antonia Katana[1] & Meena Raj[1]
[1]Lewisham and Greenwich NHS Trust, Queen Elizabeth Hospital, London, United Kingdom; [2]Barts and The London School of Medicine and Dentistry, London, United Kingdom

We present an 8-year-old black African girl with no significant past medical history. The patient presented with a 7-month history of profuse watery diarrhoea after moving to the UK from Nigeria. There was no history of bloody stools, abdominal pain or vomiting. The diarrhoea had worsened to approximately 10 watery episodes per day. She was noted to have progressive neck swellings with 4kg weight loss over this time, prompting emergency department attendance. There was no history of night sweats or fever. Her weight at initial assessment was 19kg. Extensive infection screen was unremarkable, including negative stool, HIV1/2 antibody, TB gamma interferon, gastric lavage and Mantoux testing. Biochemistry results were largely unremarkable, but with a noted raised calcitonin of 117,896 ng/l (reference range: 0-6.4ng/l). Plasma and urinary metanephrine levels were normal, as were parathyroid and thyroid hormone levels. The patient had ultrasound and CT imaging of her neck, chest, abdomen and pelvis. Ultrasound imaging of the thyroid gland demonstrated suspicious inhomogeneous calcified nodules. Multiple enlarged lymph nodes were visualised in the anterior and posterior triangle of right neck and left anterior neck, containing internal calcification (the largest measuring 30x27mm). Chest imaging revealed enlarged lymph nodes and scattered lung nodules. Sclerotic lesions were identified in the sacrum, iliac bone and vertebral bodies. Infiltrative pathology was also demonstrated in the pericardial area. The imaging was suggestive of an extensive malignant process, likely arising from the thyroid. Differentials included tuberculosis, carcinomatosis and sarcoidosis. The patient underwent biopsy, revealing a diagnosis of metastatic medullary thyroid cancer (MTC), with disease in thyroid, lymph nodes, lungs and bones. MTC accounts for approximately 5% of paediatric thyroid malignancies, with an incidence of 0.27/1,000,000 cases/year. MTC originates from parafollicular C-cells; these neuroendocrine cells produce calcitonin and are not responsive to thyroid stimulating hormone. Tumour secretion of calcitonin and calcitonin-gene related peptide are known causes of diarrhoea. While 80% of MTC cases are sporadic, familial forms exist within multiple endocrine neoplasia II (MENII) syndrome. Genetic screening of this patient was consistent with MEN 2b. The MEN2 form of MTC is caused by mutations in the RET proto-oncogene. Therefore, in children with MEN2 and advanced MTC, the RET tyrosine kinase pathway is a target for treatment. The patient underwent thyroidectomy with bilateral neck dissection with a plan to start RET inhibitor therapy in the following weeks. This case highlights the importance of considering thyroid pathology in children presenting with chronic diarrhoea.

JOINT335

A unique case of both adrenal and extra-adrenal paragangliomas in a patient with parkinson's disease

Soe Aye[1], Theik Oo[1], Nyein Lwin[1] & Yasir Al-Rawi[1]
[1]Salisbury NHS Foundation Trust, Department of Elderly Medicine, Salisbury, United Kingdom

Background
Co-existence of Paraganglioma (Phaeochromocytoma) and Parkinson's Disease (PD) in the same patient is exceptional and it is hypothesised that genetic predisposition to the two is contradictory. Only around five previous cases are recorded in the literature, all with paraganglioma found incidentally in either an adrenal or extra-adrenal location (never both). Clinically both are associated with supine hypertension and orthostatic hypotension (OH) making the management of blood pressure (BP) changes of PD in the context of paraganglioma that much more complicated.
Purpose
To highlight a) the unusual nature of this combination of illnesses and b) the difficulties of diagnosis and management when they co-exist.
Case description
A 75-year-old white British gentleman with a history of PD, hypertension, diabetes mellitus and gout was admitted to the hospital having been found on the floor at home. After further assessment for ischaemic-looking toes, a CT-angiogram revealed three incidental abdominal masses that were avidly contrast-enhancing raising the possibility of adrenal mass with further related mesenteric nodules. Biochemistry showed raised serum chromogranin A and B, urinary 24-hour normetanephrine and 3-methoxytyramine (3-MT). As 3-MT is a metabolite of dopamine it is raised in the presence of iatrogenic levodopa making interpretation confusing. Urinary 24-hour metanephrines were normal. MIBG (metaiodobenzylguanidine) scan supported a diagnosis of phaeochromocytoma with extra-adrenal secondaries. Although treatment of hypertension in paraganglioma depends on alpha and beta-blockers in our patient, who also suffered from problematic OH, such vaso-active medications were undesirable. He was discharged on pyridostigmine for OH with monitoring of hypertension and further oncology review. He was subsequently re-started on ramipril for control of symptomatic high systolic BP.
Conclusions
This case describes for the first time in literature, as far as we are aware, the presence of both adrenal and extra-adrenal paragangliomas in a patient with PD. It also highlights the complexities of diagnosis and management.

Pediatric papillary thyroid carcinoma
Amira Bouchenna[1], Abdelghani Tibouk[1], Brahim Ghennam[1], Yasmine Yahia Messaoud[1], Walid Yacine Mohamed Cherif[1], Meriem Medjaher[1], Kacem Salhi[1] & Meriem Bensalah[1]
[1]Central Hospital of Army Algiers, Algiers, Algeria

Introduction
Papillary thyroid cancer rarely affects children. More aggressive in form, it is often metastatic upon diagnosis; these metastases most often concern cervical adenopathies and the lung. Its prognosis remains excellent because metastases generally respond well to surgery and treatment with radioactive iodine.
Material and method
This is a retrospective study of 13 patients followed up at our facility between 2003 and 2024. A total of 13 children, sex ratio 2.25 girls, average age 14.84 years [5-18 years], one child had a history of cervical irradiation for lymphoma. All children had undergone total thyroidectomy with at least central lymph node dissection. Tumor size 21.11 mm vascular emboli, thyroid invasion and extrathyroidal invasion were noted in half of the patients. 8 patients had metastatic adenopathies, 5 of them pulmonary metastases and one patient a cranial metastasis revealing her thyroid microcarcinoma. The average iodine activity received was 300mci [30-900mci], unfortunately one patient had as a side effect the development of primary ovarian insufficiency. Currently, 9 patients are in remission, lesion stability is noted in 3 of them and one patient is lost to follow-up.
Discussion/Conclusion
The occurrence of papillary thyroid carcinoma in children is a source of anxiety for those around them and for the doctor. However, early diagnosis, as well as intensive management, most often allow stability and cure.

JOINT2118
Gastric microbiota and antioxidants in patients with autoimmune atrophic gastritis and gastric neuroendocrine tumors
Justine Kaupe[1], Helvijs Niedra[2], Rihards Saksis[2], Ilona Mandrika[2], Indra Zeltina[1], Kristine Bernarde[3], Vita Rovite[2] & Ilze Konrade[1]
[1]Rīga Stradiņš University, Riga East University Hospital, Endocrinology, Riga, Latvia; [2]Latvian Biomedical Research and Study Centre, Riga, Latvia; [3]Riga East University Hospital, Riga, Latvia

Autoimmune atrophic gastritis (AAG) is an organ-specific autoimmune disease that is primarily asymptomatic in the early stages, and often the cause of these AAG cases is unclear. AAG exhibits vague clinical manifestations and is accompanied by the development of other autoimmune disorders and nutritional malabsorption. It has been proposed that gastric microbiota may have an essential impact on immunological processes within the gastric tissues. However, the changes in gastric microbial communities during AAG development and their potential impact on further AAG and gastric neuroendocrine tumor (GNET) development are still largely understudied.
Objectives
This study aimed to examine the gastric microbiome composition in gastric fluid samples, determine selenium, and neopterin concentrations in blood samples from patients with AAG, GNET, and healthy controls.
Materials and Methods
A total of 25 participants were included, comprising nine AAG patients, nine GNET patients, and seven control patients. Patients underwent esophagogastroduodenoscopy during which gastric fluid was collected. Bacterial DNA was extracted from gastric fluid samples using the Qiagen PowerFecal Pro Kit. Sequencing was performed on an Illumina MiSeq platform. Biochemical markers, such as selenium, and neopterin, were determined from blood samples.
Results
The study assessed microbial diversity and abundances across AAG, NET, and controls. Genera identified included *Streptococcus*, *Rothia*, *Helicobacter*, *Actinomyces*, *Veillonella*, and *Prevotella*. Significant changes were observed in four genera in AAG and six in NET, compared to controls. Compared to the control group, AAG patients showed the highest increase in *Rothia* abundance and the greatest reduction in *Haemophilus*. Similarly, in the NET group, *Rothia* also showed the highest increase, while *Gemella* exhibited the greatest reduction. The NET group was the most heterogeneous. Median plasma selenium levels were 97.17 $\pm$ 21.84 µg/l in AAG, 105.29 $\pm$ 21.15 µg/l in GNET, and 103.31 $\pm$ 29.09 µg/l in controls. Neopterin levels were 2.84 $\pm$ 0.48 ng/mL in AAG, 3.68 $\pm$ 1.58 ng/mL in GNET, and 2.95 $\pm$ 0.80 ng/mL in controls. No significant differences were observed in selenium or neopterin levels among groups.
Conclusions
Our data show that the number of identified species was similar across groups; however, significant changes were observed in the evenness metric of the identified species. Furthermore, differential abundance testing revealed that the *Rothia* genus exhibited the highest increase in both AAG and GNET groups compared to controls. No significant differences were found in biochemical markers. While this study provides initial findings, further research is essential to fully comprehend AAG and GNET. Funding:lzp-2022/1-0102.

JOINT1105
Papillary thyroid carcinoma: a case of pulmonary metastasis
Vivian Morales Venegas[1], Leonor Hinojosa Amaya[1,2], Karla Hernández Trejo[1] & Sandra Sanchez García[1]
[1]Universidad Autonoma de Nuevo León, Departamento de Pediatria, Monterrey, Nuevo Leon, Mexico; [2]Hospital Universitario Dr. José Eleuterio González, Pediatrics, Monterrey, Mexico

Introduction
The papillary thyroid carcinoma (PTC) is the most common type of thyroid cancer, accounting for approximately 85% of all thyroid carcinoma cases. It is a well-differentiated cancer that is generally associated with slow tumor growth and a favorable prognosis. However, there are variants of PTC that can exhibit more aggressive behavior. Pulmonary metastasis in papillary thyroid carcinoma (PTC) is an uncommon but clinically significant manifestation of this disease.
Case Presentation
A 9-year-old female presented with an increase in volume in the anterior neck with a family history of a father with prostate cancer and a mother with a benign breast tumor. On physical examination, she exhibited bradylalia, dry skin, an asymmetrical area of alopecia on the scalp, and an anterior cervical region

enlargement of approximately 6 cm associated with three cervical lymph nodes. A thyroid profile was conducted showing TSH >100 µUI/mL, free T4 at 0.234 ng/dL, total T4 at 2.16 µg/dL, and total T3 at 64 ng/dL anti-thyroglobulin and anti-peroxidase antibodies were present with results of 706.6 UI/mL and 535.3 UI/mL, respectively. A Doppler ultrasound reported an infiltrative lesion involving the entire gland with heterogeneous echogenicity and increased vascular flow with lymph nodes losing their morphology at levels II, III, and IV on both sides. It was classified as TIRADS 5 according to ACR classification. A fine-needle aspiration biopsy of a cervical lymph node reported metastasis of papillary thyroid carcinoma. A CT scan was performed to rule out pulmonary metastasis, which was reported as negative. A total thyroidectomy and dissection of 29 metastatic lymph nodes were performed, followed by levothyroxine replacement and a 150 mCi iodine-131 ablative dose (T3 N1b M0). Follow-up iodine-131 scans revealed radioiodine uptake in para-aortic lymph nodes and multiple lung segments. A total body scan by SPECT/CT reported metastatic tissue in the mediastinum and both lung fields leading to a second dose of iodine-131 and a plan for surgery as soon as possible.

Final Comments

The case of papillary thyroid carcinoma presented underscores the importance of early diagnosis and appropriate management of this disease, despite its generally favorable prognosis. The detection of pulmonary metastasis, although uncommon, emphasizes the need for thorough follow-up and a multidisciplinary approach to treatment. It is crucial for healthcare professionals to be vigilant for signs of progression and to conduct continuous follow-up to ensure the best possible quality of life.

JOINT1451

Oestradiol: immunoassay measurement can be inaccurate in patients taking fulvestrant

Alice Stephenson[1], Rosie Forster[2], Finlay MacKenzie[2], Rachel Marrington[2], Megan Dolan[1] & James M. Hawley[1]

[1]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [2]Birmingham Quality UKNEQAS, Birmingham, United Kingdom

Introduction

Fulvestrant is a selective oestrogen receptor regulator and Exemestane is a steroidal aromatase inhibitor therapy, both used in the treatment of oestrogen receptor positive breast cancer. Most manufacturers of oestradiol (E2) immunoassays state that Fulvestrant interferes in their assay, some also state that aromatase inhibitors may interfere.

Method

Sample pools ($n=3$) were prepared from off-the-clot human serum obtained from female donors: Sample A – the base serum with no added analytes, Sample B – the base pool with Fulvestrant (25 ng/mL) added, and Sample C – the base pool with Exemestane (150 pg/mL) added. The samples were distributed to all participants measuring E2 in the UK NEQAS for Steroid Hormones EQA Scheme (Distribution 523). The cross-reactivity of each method was calculated for both drugs, comparing the results obtained from the base pool with those from the spiked samples. Participants were asked to answer some web Q&A's on how requests are processed for patients on Fulvestrant and Exemestane.

Results

No significant changes in E2 concentrations were observed in samples containing 150 pg/mL Exemestane when compared to the base pool. However, in samples containing 25 ng/mL Fulvestrant a positive bias was observed for several methods. A large positive bias was observed in the Siemens ADVIA Centaur and Siemens Atellica methods. Cross-reactivity was also observed in the Abbott Alinity and Abbott Architect methods but to a lesser extent. Negligible cross-reactivity was observed in other immunoassay methods (Beckman Access/DxI, Roche Cobas, Roche Cobas Pro, QuidelOrtho) and the LC-MS/MS group. The web Q&A's received 158 responses (response rate 56%). Of the respondents, 85% analysed all E2 requests and did not vet on the basis of clinical details. 27% of respondents refer E2 requests for analysis by LC-MS/MS at the request of the clinician or after reviewing clinical details. 59% of respondents did not append comments to E2 results in regard to potential assay interference from medications including Fulvestrant.

Conclusion

Fulvestrant significantly interferes in some E2 immunoassays and may lead to over-estimation of E2 concentrations in patients receiving therapy. While most manufacturers state that Fulvestrant interferes in E2 immunoassays, many laboratories do not act on this information. This could lead to inappropriate management of patients being treated with Fulvestrant.

JOINT1734

SPECT/CT skeletal muscle cancer in bronchial cancer, about a case

Redhouane Longo[1] & Mourad Benrabah[1]

[1]Regional University Military Hospital, Oran, Algeria

Introduction

The most common sites of distant metastasis from bronchial cancer are lung, liver, bone, adrenal and central nervous system. While muscle metastases are rarely described in the literature. In clinical series, muscle is metastatic site in 0.03 to 0.16% of cancers while autopsy series reported a frequency up to 16%. This difference is due to the clinical aspects which are variable, This may lead to misdiagnosis.

Objective

Interest in the completion of SPECT/CT slices complementary to planar images in the presence of clinical signs of calls with a focus of hyperfixation to planar images of bone scintigraphy in the diagnosis and therapeutic guidance.

Materials and methods

We report the case of a patient referred for an extension assessment of bronchial neoplasia. A bone scan completed with SPECT/CT was performed with a GE NM/ CT DISCOVERY 670 Gamma camera.

Results

A 79-year-old patient with firm, painful swelling of the groin that was initially inconclusive on scintigraphy. Whereas, 2 years later, a control scan was performed to establish a hyperfixation focus of the metaphyseal regionproximal diaphysal of the left femur corresponding to bone lysis contiguous to an adjacent soft tissue mass extending into the spinal canal on SPECT/CT slices. The ultrasound-guided biopsy concluded an infiltration of muscle by a neoplastic malignant proliferation of epithelial nature (adenocarcinoma) with positivity to thyroid transcription factor 1 (TTF1) and CK (AE1/AE3) consistent with a pulmonary origin which confirms the loco-regional extension of muscle ass to adjacent bone. The patient was treated with chemotherapy using gemcitabine and carboplatin.

Discussion

These metastases often occur during the course of a known cancer and are rarely as revealing as in our case. SPECT/CT sections confirm the presence of muscle mass without being able to decide on its metastatic nature. They were used to guide the biopsy. In our patient, the ultrasound biopsy confirmed the diagnosis of muscle metastasis of a pulmonary adenocarcinoma due to the positivity of tumor cells at TTF1. The SPECT/CT scan of the region with signs of call during the course of a bronchial cancer allowed to correct the therapeutic conduct in the presence of skeletal muscle metastasis that escaped radiological exploration.

Conclusion

Skeletal muscle metastasis is a rare event in the course of bronchial cancer. The clinical presentation is often misleading leading to a delay in diagnosis and inappropriate therapeutic conduct. Interest in performing SPECT/CT slices in the presence of clinical signs with hyperfixation focus.

Epidemiologic profile of differentiated thyroid cancer in algeria

Imane Negab[1,2], Aicha Bouzid[3,4], Karine Benachour[1], Malha Azzouz[5] & Mustapha Oumouna[1]

[1]Dr Yahia Fares of Medea Algeria, Biology, Medea, Algeria; [2]Dr Yahia Fares University, Biology, Biology, Medea, Algeria; [3]University of Medecine of Tizi Ouzou, Endocrinology, Tizi Ouzou, Algeria; [4]University of Medecine of Tizi Ouzou, Alger; [5]University of Medecine of Algiers, Ibn Ziri Bologhine Hospital, Endocrinology, Algiers, Algeria

Introduction

Differentiated thyroid carcinoma is the most common endocrine cancer. The aim of the study was to assess the clinical and paraclinical characteristics of differentiated thyroid carcinoma in order to determine its epidemiology in Algeria.

Patients and Methods

This is a descriptive retrospective epidemiological study of differentiated thyroid cancer, evaluating the period from January 1, 2019 to the end of 2023. We collected data from the patient files of the endocrinology department of the EPH Ibn Ziri de Bologhine in Algiers.

Results

1275 patients were included. The incidence rates of differentiated thyroid cancer during the five-year study period (2019-2020-2021- 2022-2023) were 2.78%, 4.88%, 3.36%, 6.36%, and 6.12%, respectively. The mean age of our patients was

42.79 ± 12 years. There was a clear female predominance with 84% women and 16% men, i.e. a F/M sex ratio of 5. The predominant age group was between the third and fifth decades. A family history of goiter was found in 21.18% of cases and of thyroid cancer in 7.37%, while 71.4% of patients had no history of thyroid cancer. No history of childhood thyroid irradiation was found. 43.06% of our patients consulted for thyroid nodule, 25.88% for multinodular goiter, 23.53% for cervical adenopathy and 1.96% for distant metastasis, although the finding was incidental in 5.57% of the cases. Total thyroidectomy was the initial treatment in all patients. The diagnosis of differentiated thyroid cancer was based on anatomopathologic examination of the surgical specimen, 79.14% of cases being papillary carcinoma and 20.86% being vesicular carcinoma. 20.91% of papillary carcinomas were microcarcinomas. 36.24% of the patients had tumors smaller than 1 cm, 28% between 1 and 2 cm, 18.90% between 2 and 4 cm and 16.86% larger than 4 cm. All patients received irradiation and thyroid hormone therapy. Close and regular follow-up allowed the detection of lymph node metastases in 23.22% of patients by anatomopathologic examination, while distant bone and lung metastases were observed in only 2.51% and 1.57% of patients, respectively.
Conclusions
Establishing the epidemiological profile of differentiated thyroid cancer contributes to better patient management and can help identify the risk factors and etiology of the disease. Collaboration between different departments (consultation, radiology, molecular biology and surgery) is needed to optimize patient management in Algeria.

Uncommon thyroid cancer concurrence: a case of papillary micro-carcinoma and medullary thyroid carcinoma

Aiste Stonyte[1], Emilija Tumenaite[1], Valdas Sarauskas[2,3] & Raimonda Klimaite[4]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Endocrinology, Kaunas, Lithuania; [3]Department of Pathology, Academy of Medicine Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Endocrinology, Kaunas, Lithuania

Introduction
Papillary thyroid carcinoma (PTC), originating from follicular epithelial cells, accounts for over 90% of thyroid cancers. In contrast, medullary thyroid carcinoma (MTC) arises from the parafollicular cells, and is characterized by the production of calcitonin. The simultaneous occurrence of PTC and MTC is a rare phenomenon and occurs in less than 1% of thyroid tumors. Therefore, it is crucial to conduct further research on the outcomes of concurrent PTC and MTC.
Case
A 72-year-old female had been monitored for 3 years due to nodular thyroid disease and subclinical hyperthyroidism. Hashimoto's thyroiditis and Graves' disease were excluded. **Thyroid ultrasound** There are hypoechoic nodules in the upper part of the thyroid (1.7 x 1.1 cm) and in the isthmus (0.7 cm). Fine-needle aspiration biopsy (FNAB) was performed. **Thyroid scintigraphy with 99mTc** "Cold" nodule in the thyroid gland. **Cytological examination** Not possible to rule out a tumor. **Treatment** In 2018, the patient underwent thyroidectomy and neck lymphadenectomy. Levothyroxine 100 mg/day for replacement maintains stable euthyroidism. **Microscopic examination** Papillary thyroid microcarcinoma pT1a / Medullary thyroid carcinoma pT1b. No mutations were found in KRAS codons 12/13, 61, 117, 146, or in NRAS codons 12/13, 59-61, 117, 146. **Genetic consultation** No known pathogenic or potentially pathogenic mutations in the RET gene, nor mutations of unknown clinical significance or likely benign sequence alterations were detected. **Laboratory tests** Pre-surgery calcitonin level was measured at 17.1 pmol/l. The following markers were monitored for the evaluation of recurrence post-surgery: CEA, calcitonin, thyroglobulin, and anti-Tg. All values remained within the reference range. **Follow-up** The patient undergoes annual oncological surveillance for thyroid carcinoma recurrence, including neck, chest, and abdomen imaging. No metastasis or recurrence has been observed. Neck ultrasound shows no pathological changes.
Conclusions
The concurrent occurrence of PTC and MTC in a single patient is exceptionally rare. Therefore, this case provides valuable insights into the management of simultaneous thyroid malignancies, emphasizing the importance of early detection and long-term follow-up to monitor for recurrence or metastasis.

Pituitary Adenoma as the First Manifestation of MEN1: A Case Report

Afrah El Kaissi[1], Meriem Benrkia[1], Jade Issouani[2] & Ahmed Anas Guerboub[2]
[1]CHU Ibn Sina - Rabat, Endocrinology, Rabat, Morocco; [2]Hôpital Militaire d'Instruction Mohamed V - Rabat, Endocrinology, Rabat, Morocco

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a rare autosomal dominant disorder characterized by synchronous or metachronous neuroendocrine tumors. The three main clinical features of this disease are primary hyperparathyroidism (pHPT), duodenal-pancreatic neuroendocrine tumors, and anterior pituitary tumors (1,2). pHPT is the most common and often the first clinical manifestation in 90% of cases (3). We report a rare case of MEN1 in which a pituitary adenoma appeared before pHPT, emphasizing the need to consider other early manifestations of the disease.
Case Report
A 57-year-old female with a history of bilateral cystic mastopathy and LADA (Latent Autoimmune Diabetes in Adults), developed a 5 mm microprolactinoma at age 27. The adenoma was managed with transsphenoidal surgery, complicated by corticotropic insufficiency, which was corrected with hydrocortisone replacement. At age 51, 24 years after the pituitary adenoma, pHPT was diagnosed late, following the development of renal (kidney stones) and bone (recurrent fractures) complications. Histopathological examination confirmed a parathyroid adenoma. MEN1 screening did not reveal any additional components beyond the two already identified.
Discussion & Conclusion
MEN1 is an uncommon condition, with an estimated prevalence of 3 to 20 cases per 100,000 individuals (1). In this disorder, pHPT is the first clinical manifestation in 90% of cases (3). However, although less frequent, a pituitary adenoma can also present as the first expression of the disease (4). It is estimated that about 30-40% of MEN1 patients develop pituitary adenomas during the course of the disease. Among these, approximately two-thirds are classified as microadenomas, with prolactinomas predominating in 65% of cases (3). This case highlights the importance of considering pituitary adenoma as an early manifestation of MEN1, without necessarily expecting pHPT to appear first.

Introduction
Radioactive iodine (RAI) therapy is an adjuvant treatment to reduce the risk of recurrence of papillary thyroid cancer (PTC).
Aim
To investigate the modalities and duration of follow up after RAI treatment.
Materials and Methods
Retrospective study of 22 patients with papillary thyroid carcinoma, treated with RAI and followed between the years 2020 and 2023.
Results
The mean age of patients was 43 years, with a female predominance (sex ratio = 0.19). The main symptom was a thyroid nodule in 19 cases, cervical adenopathy in 2 cases, and dysphagia in 1 case.Treatment consisted of Total thyroidectomy with central lymph node dissection in all patients, divided into total thyroidectomy in 10

patients and totalization after a first loboisthmectomy in 12 patients with lymph node dissection in 2 patients. The diagnosis was based on anatomopathological examination, which revealed papillary carcinoma in all patients. Treatment with RAI was carried out in 100% of cases, with a mean TG - OFF of 3.54 and mean Anti TG of 23.96. A whole-body scan was performed three days after high-dose iodine administration showing thyroid residues with no suspicious focus on the rest of the body in all patients. Biological follow up, carried out 4 months after the treatment, with an average TG of 0.1 and average anti TG of 0.2. During follow-up, every 3 to 6 months for the first 2 years, then at one year, none of the patients had a clinical, biological or radiological recurrence.
Conclusion
Surveillance in post RAI therapy in papillary thyroid cancer is crucial for early detection of recurrence and ensuring optimal patient management. Monitoring modalities, including serum thyroglobulin, cervical ultrasound, and, when necessary, functional imaging, are essential for assessing treatment response and guiding therapeutic strategies.

An unusual first manifestation of pheochromocytoma leading to the discovery of a MEN2A family

Anna Catarina Gatzk de Arruda[1], Natasha Ludwig[1], Luciana A. Castro-neves[2], Ana O. Hoff[2], Tânia Longo Mazzuco[1] & Alexandre Jose Carrilho[1]
[1]Universidade Estadual de Londrina, Londrina, Brazil; [2]Instituto do Câncer do Estado de São Paulo, Universidade de São Paulo, São Paulo, Brazil

Introduction
Multiple Endocrine Neoplasia type 2A (MEN2A) is an autosomal dominant hereditary cancer syndrome caused by a germline mutation in the REarrenged during Transfection (RET) proto-oncogene. Its classic form comprises the association of medullary thyroid carcinoma (MTC), phaeochromocytoma (PHEO), and primary hyperparathyroidism. We report a case of a patient, and his first-degree relatives, diagnosed with MEN2A at the age of 23, who presented bilateral PHEO as the first manifestation.
Objective
To describe the clinical and genetic aspects of a family with MEN2A.
Methods
Review medical records and telemedicine interviews of the index case and his relatives to collect clinical information related to MEN2A.
Results
The index case was diagnosed with bilateral PHEO and MTC at the age of 22 and 26 respectively, and the allelic variant c.1900T>C;p.Cys634Arg in exon 11, rs75076352 was identified. From there, 13 family members were screened: four siblings, his only son, and eight nephews and nieces. The genetic testing found the allelic variant in eight relatives and, one of them who had not been tested manifested the disease in the follow-up. Of the ten individuals with the syndrome, eight underwent a total thyroidectomy due to MTC, one had suspicious nodules on fine needle aspiration biopsy (FNAB), and another had elevated calcitonin levels at the age of 7. Both were referred for thyroidectomy. The age at diagnosis of MTC ranged from 8 to 35 years. PHEO was diagnosed in six, all of them with bilateral involvement, and the age at diagnosis ranged from 23 to 34 years, except for one case under 20 years of age. Two patients (the index case and his brother) were diagnosed with PHEO before MTC, both had benign FNAB of thyroid nodules. Two cases presented with normocalcemic hyperparathyroidism.
Discussion
In MEN2A, PHEO is frequently diagnosed in the third and fourth decade of life and rarely prior to MTC diagnosis. In this study, we report two patients from the same family with bilateral PHEO as the first manifestation of MEN2A.
Conclusion
PHEO has a strong association with genetic syndromes when diagnosed in young patients, as well as in its bilateral form. Reporting unusual presentations of rare syndromes could help us improve the diagnosis and follow-up of these patients.

The hidden danger of small thyroid nodules: unmasking hereditary medullary thyroid carcinoma

Tamar Peshkova[1], Liana Jashi[2] & Salome Glonti[3]
[1]Batumi Shota Rustaveli State University, Batumi, Georgia; [2]Avicenna - Batumi Medical University, Batumi, Georgia; [3]Batumi Shota Rustaveli STate University, Batumi, Georgia

Background
Medullary thyroid carcinoma (MTC) is a neuroendocrine tumour originating from parafollicular C cells, with both sporadic and hereditary forms. Early detection is crucial due to its metastatic potential. Serum calcitonin is a key biomarker for MTC, often identifying cases before clinical symptoms arise. Given its autosomal dominant inheritance in hereditary cases, genetic screening plays a pivotal role in at-risk individuals.
Case Presentation
A 41-year-old woman seeking pregnancy consultation underwent thyroid ultrasound, revealing a 5×3.3 mm nodule with vague margins, hypoechoic echotexture, microcalcifications, and peripheral vascularization. Thyroid function was normal. Fine-needle aspiration returned a Bethesda V classification, suspicious for MTC. Serum calcitonin was 16 pg/mL. Family history revealed her paternal aunt and cousin had confirmed MTC, and her father had undergone a thyroidectomy two decades prior with unknown histology. A prior ultrasound a year earlier had categorized the nodules as TIRADS 1, but no family history was elicited at that time, delaying suspicion of hereditary MTC. The patient underwent total thyroidectomy. Histopathology was inconclusive, prompting immunohistochemical analysis, which confirmed MTC in the 5×3.3 mm nodule, positive for calcitonin, carcinoembryonic antigen (CEA), and thyroid transcription factor-1 (TTF-1). The final staging was pT1aN0M0R0. Postoperatively, serum calcitonin and CEA levels were undetectable. Genetic testing for RET mutations was recommended, and first-degree relatives were advised to undergo screening.
Discussion
This case underscores the critical importance of serum calcitonin measurement and family history assessment in thyroid nodule evaluation. Small nodules, often considered clinically insignificant, may harbour malignancy. The presence of microcalcifications in even tiny nodules should raise suspicion, warranting further investigation. Routine calcitonin screening facilitates early MTC detection, optimizing patient outcomes. Given hereditary MTC's autosomal dominant inheritance, timely genetic screening and family member evaluation is essential to prevent delayed diagnosis and improve prognosis.
Conclusion
Small thyroid nodules, particularly those with microcalcifications, should not be overlooked, as they may indicate hereditary MTC. Integrating calcitonin measurement, thorough family history assessment, and genetic testing into routine thyroid evaluations is crucial for early detection and timely intervention, improving patient management and familial risk assessment.

Ectopic cushing's syndrome associated with poorly differentiated nasal squamous cell carcinoma

Takahiro Shimada[1], Yuki Tsujimoto[1], Kennosuke Ohashi[1], Hiroshi Asano[1], Ai Iwauchi[2], Nei Fukasawa[2], Miku Maeda[2], Kenji Yamashiro[1] & Rimei Nishimura[1]
[1]The Jikei University School of Medicine, Department of Diabetes, Metabolism and Endocrinology, Tokyo, Japan; [2]The Jikei University School of Medicine, Department of Pathology, Tokyo, Japan

Introduction
Ectopic Cushing's syndrome (ECS) is hypercortisolism caused by an extra-pituitary ACTH-producing tumour, and accounts for 10-20% of all Cushing's syndrome (CS) cases. The common underline diseases of ECS are small cell lung cancer, bronchial neuroendocrine neoplasia (NENs), pancreatic NENs, thymic NENs, and pheochromocytoma. However, ECS in nasal cancer, especially nasal squamous cell carcinoma is extremely rare.
Case presentation
A 29-year-old pregnant woman presented with reduced olfactory and visual acuity. A contrast-enhanced CT revealed a tumour in the right nasal cavity. Biopsy confirmed poorly differentiated squamous cell carcinoma with neuro-endocrine differentiation. She delivered a male infant via cesarean section at 33 weeks and 4 days. Postpartum imaging, including MRI and 18-FDG-PET/CT, revealed the metastases in right pharyngeal lymph nodes and the left femoral neck, derived from inoperable nasal cavity carcinoma. Thus, chemotherapy was initiated, along with proton beam therapy to the primary lesion. Despite first-line (cisplatin and etoposide) and second-line (nivolumab) chemotherapy, the disease progressed with metastases in the liver, pleura, and breasts. Five months after the initial diagnosis, she developed hyperglycemia (plasma glucose 11.4 mmol/l, HbA1c 6.0%) and hypokalemia (K 2.4 mEq/l), prompting referral to our department. A month prior, hypokalemia had not been present. She had typical signs and symptoms of CS as follows; significant elevation of serum morning ACTH (221.0 pg/mL), cortisol (126 μg/dL), and urine free cortisol (3740 μg/day).

Lack of cortisol suppression of the high dose dexamethasone test led to the diagnosis of ECS due to nasal cavity carcinoma. She started metyrapone treatment with initial daily dose of 750 mg. Treatment with metyrapone 1000 mg and osilodrostat 2 mg successfully reduced cortisol levels (serum morning cortisol: 13.6 μg/dL, urine free cortisol: 51 μg/day) without serious side effects.
Conclusion
This case highlights the rare occurrence of ECS in nasal squamous cell carcinoma. Although the patient did not initially have the Cushing's signs, overt symptoms with ECS developed rapidly with disease progression. Further accumulation of cases is needed for better understanding of the characteristics and management of ECS due to nasal squamous cell carcinoma.

Differentiated high-grade thyroid carcinoma in pregnancy

Laura Dudonytė[1], Agnė Rimkutė[1] & Aistė Kondrotienė[2]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Subacute thyroiditis during pregnancy is a rare condition, with an incidence of 10-20 cases per 1,000,000 pregnancies [1]. It can mimic thyroid cancer, which has an incidence of 3.6-14 cases per 100,000 pregnant women [2].
Case Presentation
A 31-year-old woman, at 6 weeks of pregnancy, presented with right-sided neck pain and difficulty swallowing. Laboratory tests revealed elevated inflammatory markers: C-reactive protein 190 mg/l, erythrocyte sedimentation rate 27 mm/h, and white blood cell count (WBC) 10.9 x 10^9/l, ANtiTPO, AntiTg – negative, euthyrosis. Ultrasound of the thyroid showed a significantly enlarged right lobe, containing a large, hypoechoic, heterogeneous, and hypervascular nodule measuring approximately 4.4 x 3.3 x 3.5 cm. The nodule exhibited multiple calcifications of varying sizes, along with avascular areas, while the left lobe appeared normal. A suspicious 0.5 cm lymph node was identified in the right side of the neck (zone IV). Based on these findings, a percutaneous fine needle aspiration biopsy was performed under ultrasound guidance, with three tissue columns collected for histopathological examination. The patient was started on ibuprofen for pain and inflammation, and over the course of her treatment, there was improvement in the inflammatory markers, and her symptoms vanished. Biopsy results revealed differentiated high-grade thyroid carcinoma (DHGTC) with areas of tumor necrosis. Immunohistochemistry showed that tumor cells were positive for TTF-1, PAX-8, CK-19, and weakly positive for thyroglobulin, but negative for BRAF. The Ki-67 proliferation index was 7%. Surgical treatment was recommended. Due to the pregnancy, surgery was planned for the second trimester. A total thyroidectomy was performed, and a lymph node in zone VI, measuring 4 mm posterior to the right thyroid lobe, was also removed. The histological examination of the excised tissue confirmed the diagnosis of DHGTC carcinoma, staged as pT3 N0a LVI1. Following surgery, the patient was started on thyroxine replacement therapy with TSH suppression. In conclusion, this case highlights the diagnostic challenge of distinguishing subacute thyroiditis from thyroid cancer during pregnancy. Despite the initial suspicion of subacute thyroiditis, further investigation revealed high-grade differentiated thyroid carcinoma. DHGTC has an intermediate prognosis, falling between well-differentiated thyroid carcinoma and anaplastic thyroid carcinoma [3]. Well-differentiated tumors do not require immediate surgical treatment but only observation during pregnancy. On the contrary, more aggressive tumors (as in our case), also undifferentiated, require surgery during pregnancy, as delay in such circumstances can significantly reduce survival [4].

Radiolabeled somatostatin receptor antagonist in patients with metastatic pheochromocytoma or paraganglioma; dosimetry, efficacy and safety evaluation

Sofia-Maria Lider-Burciulescu[1,2], Felix Schmidt[1], Lisa McDougall[1], Peter Bernhardt[3], Abdulrafee Mushaweh[1], Andreas Bauman[4], Melpomeni Fani[5], Emanuel Christ[6,7] & Damian Wild[1,7]
[1]University Hospital Basel, Clinic for Radiology and Nuclear Medicine, Nuclear Medicine, Basel, Switzerland; [2]"Ana Aslan" National Institute of Geriatrics and Gerontology, Endocrinology, Bucharest, Romania; [3]University of Gothenburg, Department of Medical Radiation Sciences, Gothenburg, Sweden; [4]University Hospital Basel, Department of Medical Radiation Sciences, Basel, Switzerland; [5]University Hospital Basel, Radiopharmaceutical Chemestry, Basel, Switzerland; [6]University Hospital Basel, Endocrinology, Basel, Switzerland; [7]University Hospital Basel, ENETS Center of Excellence for Neuroendocrine and Endocrine Tumors, Basel, Switzerland

Introduction
Metastatic pheochromocytomas and paragangliomas (mPPGLs) are rare neuroendocrine tumors with a variable treatment response. A new radioligand therapy (RLT), a radiolabelled somatostatin receptor antagonist (^{177}Lu-DOTA-JR11) which use has proven high efficacy in patients with NETs G1-G3, may offer increased tumor doses compared to standard RLT with 177Lu-DOTA-TOC in patients with mPPGLs which express somatostatin receptor subtype 2.
Aim
The main objective was to evaluate the tumor absorbed dose of ^{177}Lu-DOTA-JR11 and ^{177}Lu-DOTA-TOC in the same patients with progressive mPPGLs, non-responsive to conventional treatment. Secondary objectives included efficacy and safety assessment of ^{177}Lu-DOTA-JR11 in these patients.
Material and methods
We retrospectively retrieved data of 6 patientswith mPPGLs, treated with 1-2 cycles ^{177}Lu-DOTA-TOC at a standard injected activity of 7.4 GBq followed in an interval of 10-12 months by one cycle ^{177}Lu-DOTA-JR11 (2 GBq/m2 $\times$ body surface area). Tumor absorbed doses were computed using the 75 keV-window for 161Tb and the 208 keV-window for ^{177}Lu as well as the Monte-Carlo-based OSEM algorithm. Therapy efficacy was expressed as progression free survival (PFS) before and after ^{177}Lu-DOTA-JR11, symptoms control and hormonal marker response. Safety was assessed as possible adverse events associated to^{177}Lu-DOTA-JR11.
Results
Six patients (4 women; 3 PHEOs, 3 PGLs) with a median age at diagnosis of 38 (25-65), a median age when receiving first ^{177}Lu-DOTA-JR11 cycle of 57 (45-75) years and a Ki-67 between 7 and 30% were included. The median tumor absorbed dose of ^{177}Lu-DOTA-JR11 was higher compared to standard ^{177}Lu-DOTA-TOC (D=7.9 (1.1-12.1) vs. 3.7 (1.3-10.6) Gy/cycle, respectively). After one cycle of ^{177}Lu-DOTA-JR11 with a median injected activity of 3.6 GBq (2.8-4.3 GBq), patients had a higher PFS [9 (4-17) months] than before ^{177}Lu-DOTA-JR11 start [6 (2-11) months], at a median follow-up duration of 28 months. Two out of 3 patients with functional tumor were free of adrenergic symptoms after treatment. ChromograninA decreased less than baseline levels after $>$ 3 months posttreatment in 2/4 (50%) patients. The most reported adverse events were anemia grade 2 (n= 3, 50%), lymphocytopenia grade 2 and 3 (n= 3, 50%), followed by hypoalbuminemia grade 1 (n= 2, 33%). There weren't grade 4 or 5 events, thrombocytopenia or neutropenia and no kidney or liver disfunction.
Conclusion
This pilot study on mPGGLsshowed that the median tumor absorbed dose per cycle is 1.3 (0.9-3.5) times higher with ^{177}Lu-DOTA-JR11 compared to ^{177}Lu-DOTA-TOC, resulting in a longer PFS and a good clinical outcome without relevant adverse events after ^{177}Lu-DOTA-JR11 therapy.

Challenging management of paraneoplastic cushing's syndrome: a 13 year clinical journey

Ons Maaoui[1], Nadia Khessairi[1], Yesmine Merhbene[1], Elyes Kamoun[1], Fatma Chaker[1] & Malika Chihaoui[1]
[1]Rabta Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
Paraneoplastic Cushing's syndrome is an uncommon cause of endogenous hypercortisolism. Only 6% of Cushing's syndrome was caused by ectopic ACTH secondary to neuroendocrine tumors [1]. These tumors may be occult and difficult to find, and imaging results are often inconclusive.
Observation
We report a case of a 21 year old patient, who presented with a Cushing's syndrome confirmed by 48-hour low-dose dexamethasone test. On physical examination, he had melanoderma, muscle atrophy, purple abdominal striae and centripetal obesity. The ACTH-dependent character was confirmed by high ACTH level. The diagnosis was complicated with diabetes, hypertension with

severe hypokalemia, cerebral and iliac thrombophlebitis and pulmonary embolism and gonadotropin deficiency. Pituitary MRI revealed a 4.5 mm pituitary microadenoma. The patient underwent total transsphenoidal hypophysectomy and the anatomopathological examination confirmed the diagnosis of pituitary adenoma with immunohistochemistry confirming ACTH-binding character. The post operative follow-up showed the persistence of clinical and biological Cushing's syndrome with high levels of ACTH. Cervical thyroid echography and thoracic-abdominal-pelvic (TAP) CT scan showed no abnormalities besides bilateral adrenal hyperplasia and bilateral pulmonary parenchymal condensation with no pathological fixation on octreotide scintigraphy. Pleural biopsy showed a cytological aspect of tuberculosis without histological signs of malignancy. The patient underwent bilateral adrenalectomy. During the 13 years follow up the ACTH levels remained high with negative anatomic and functional imaging. At the age of 34 years old, CT TAP showed thickened micronodules of the two basal pyramids, well rounded and non-specific and octreotide scintigraphy showed a 06 mm left antero-basal pulmonary nodule intensely fixating octreotide. The patient was referred to thoracic surgery.

Conclusion

This case highlights the challenges of paraneoplastic Cushing's syndrome and the importance of vigilance in identifying ectopic ACTH-secreting tumors which can remain occult for years.

A rare source of ectopic ACTH secretion causing cyclical cushing's syndrome

Julia Calvo Latorre[1], Hassan Ibrahim[1], Muhammad Faheem[1], James Macfarlane[1], Ines Harper[1], Victoria Stokes[1], Ruth Ronneberger[1], Mark Gurnell[1] & Ruth Casey[1]
[1]Cambridge University Hospitals NHS Foundation, Diabetes and Endocrinology, Cambridge, United Kingdom

We present a rare case of a 64-year-old female with no relevant past medical history, who presented in October 2023 with a 2-month history of peripheral and facial oedema, hirsutism, sleep disturbance, muscle weakness, brain fog and new onset hypertension. She also reported some initial weight loss, so a CT of the chest, abdomen and pelvis was arranged. This revealed hyperplastic adrenal glands but no other significant findings. She was found to have a raised random cortisol (1126 nmol/l) with a high adrenocorticotropic hormone (ACTH) (98ng/l, reference $\leq$ to 50ng/l) and was referred to Endocrinology with suspicion of ACTH-dependent Cushing's syndrome. Her overnight dexamethasone suppression test was markedly elevated at 621 nmol/l (reference 0-50 nmol/l), as was her 24h urinary free cortisol (886 nmol/24h, reference 0-146 nmol/24h). The rest of her anterior pituitary profile was unremarkable. An MRI of her pituitary gland revealed an incidental 3 mm Rathke's cleft cyst, but no adenoma. Inferior petrosal sinus sampling (IPSS) was arranged 3 months after her initial presentation to exclude Cushing's disease. However, the patient reported spontaneous resolution of her symptoms, with normalisation of her blood pressure and biochemistry. A diagnosis of cyclical ACTH-dependent Cushing's syndrome was made. In June 2024, the patient's symptoms recurred, with concurrent biochemical evidence of hypercortisolism, and an urgent IPSS was arranged. This did not confirm a pituitary origin and an 18-FDG PET-CT and a pituitary and thoracic 11C-Methionine PET CT were performed to identify an ectopic origin of ACTH secretion, without any focal uptake noted on either scan. A Gallium-68 DOTATATE PET CT was arranged to look for neuroendocrine tumours as an ectopic source of ACTH and revealed focal uptake in the small bowel and 2 mesenteric lymph nodes, suggestive of a small bowel neuroendocrine tumour (NET) as the source of ectopic ACTH secretion. She was commenced on block and replace therapy with metyrapone and dexamethasone, as well as apixaban for thromboprophylaxis. She underwent surgical resection with intraoperative ultrasound guidance of two tumours found in the ileum, as well as the pathological mesenteric lymph nodes identified on PET CT, with perioperative hydrocortisone and octreotide cover. Hydrocortisone was stopped 2 weeks post-operatively following a robust early morning cortisol result and post-operative ACTH levels normalised. Histopathology confirmed a grade 2 well-differentiated mid-gut NET expressing ACTH with nodal metastases. She remains under regular endocrine follow up and is awaiting a repeat Gallium-68 DOTATATE PET CT to guide further management.

Niosome-encapsulated quercetin for enhanced thyroid cancer therapy and potential minimization of thyroid surgery

Zahra Esfandmoz[1], Hadi Tabesh[1], Hamidreza Bazrafshan[2,3] & Amirreza Amjad[1]
[1]University of Tehran, Tehran, Iran; [2]Dr. Bazrafshan Clinic, Tehran, Iran; [3]University Hospital, Munich, Germany

This study investigates a novel niosome-encapsulated quercetin delivery system for enhanced thyroid cancer therapy, exploring its potential to minimize thyroid surgery. Quercetin, a promising anti-cancer flavonoid, suffers from poor bioavailability. Nevertheless, some previous studies proved its efficiency in thyroid cancer treatment. Niosomes offer a potential solution by improving drug delivery. Quercetin-loaded niosomes were fabricated using thin film hydration and characterized for size, morphology, stability, and release profile. Dynamic Light Scattering (DLS) showed a uniform particle size of ~70 nm indicating the successful formation of nanosized vesicles suitable for cellular uptake. Scanning Electron Microscopy (SEM) confirmed spherical morphology and Zeta potential indicated a stable formulation. Stability studies demonstrated the niosomes' integrity over a period of time, proving their suitability for drug delivery applications. *in vitro* release profiles were evaluated at neutral and acidic pH. Sustained quercetin release was observed at neutral pH over four days. Critically, release was slower in acidic conditions, mimicking tumor microenvironments, suggesting potential for modulated drug release. These findings highlight the potential of niosome-encapsulated quercetin for thyroid cancer therapy. The nanosized vesicles, spherical morphology, pH-sensitive release, and stability suggest improved drug delivery and enhanced quercetin's anti-cancer activity. This targeted approach may potentially reduce the need for total thyroidectomy. Further *in vitro* and *in vivo* studies are warranted to evaluate efficacy and safety in preclinical thyroid cancer models, specifically investigating the potential to minimize surgical intervention. This research contributes to improved, less invasive thyroid cancer treatments.

Challenges in treatment of carotid paraganglioma: about a case report

Nawres Bouaziz[1], Misbah Linda[1], Rachida Bouatay[1], May Ferjani[1], Mahdi Ferjaoui[1], Amel El Korbi[1], Nawres Kolsi[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Introduction

Paragangliomas are rare neuroendocrine tumours that arise from the glomus cells of the embryonic neural crest and can be found from the skull base to the pelvis. Carotid paragangliomas are rare, hypervascular, slow-growing neuroendocrine tumours. A preliminary diagnosis can be made based on the patient's history, physical examination and imaging studies.Althoughresectionis a radical therapy for thistumor, completeresectionischallenging. Our objective is to report a rare case of carotid paraganglioma and describe its clinical presentation and management stategy.

Case report

A 15-year-old girl with a history of epilepsy and no family history of multiple endocrine neoplasia, Von Hippel-Lindau disease or pheochromocytoma presented with a 2-month history of laterocervical swelling with no signs of compression. On examination she had a laterocervical mass of 4 cm, firm, pulsatile, movable and indolent. She had no cervical lymphadenopathies or other palpable masses, and her nasopharyngeal endoscopy was unremarkable. Computed tomography (CT) and magnetic resonance imaging (MRI) showed a left laterocervical mass centred on the carotid bifurcation, measuring 44*28*25 mm, enveloping the distal part of the left common carotid artery and the initial part of the left internal and external carotid arteries, suggestive of a paraganglioma type 3 of the Shamblin classification.The urinarycatecholamineswerenegative. The patient was referred for vascular surgery.

Discussion/Conclusion

Cervical paragangliomas are rare tumors that can occur sporadically or be familial. Hereditary forms are associated with genetic mutations. Diagnosis relies on CT, MRI, and functional imaging. Management involves a multidisciplinary approach, combining medical and surgical strategies. Surgical excision remains the only curative treatment, but it carries a risk of significant postoperative sequelae. Therefore, cooperationwith an otolaryngologist and vascular surgeon duringsurgeryisrecommended due to frequent damage to carotidvessels by carotidparagangliomas. Detection of the tumor in the early stages improvessurgicaltreatmentoutcomes and reduces the number of complications. Regular postoperativecheck-ups are necessary due to possible occurrences of multiple tumors. Disclosure of interest: none declared

Kyriakou", Radiology Department, Athens, Greece; [5]Children's Hospital "P.& A. Kyriakou", Histopathology Department, Athens, Greece; [6]Children's Hospital "P.& A. Kyriakou", Dept. of B Pediatric clinic, Athens, Greece

Introduction
Precocious puberty is defined as the onset of secondary sexual characteristics before the age of eight years in females and nine years in males. It is classified as Central precocious puberty (CPP), as a result of early maturation of the hypothalamic-pituitary-gonadal axis and as peripheral precocious puberty (PPP), secondary to excess secretion of sex hormones from the gonads or adrenal glands, ectopic production of bHCG from a germ-cell tumor or exogenous sources. We aim to present a preschool girl with premature menarche and adrenarche.
Methods
A 4.5-year-old girl was referred for evaluation of precocious puberty. Her mother noticed rapid breast development as well as pubic and axillary hair the previous month. She also reported vaginal bleeding. Physical examination revealed: Tanner II-III breast, axillary and pubic hair, and a palpable mass in the lower abdomen. Laboratory investigation showed elevated estradiol, suppressed gonadotrophins and elevated adrenal androgens, while tumor markers were negative (FSH: $<$0.3mIU/mL, LH: $<$0.3mIU/mL, E2:294.70pg/mL, PRL:581μIU/mL, 17- OH-Prog:5.23ng/mL, DHEA-S:0.467μg/ml, aFP:2.6ng/ml, bHCG $<$0.1UI/lt, TSH:2.13μIU/ml), suggestive of PPP. Bone age was advanced consistent with 5.5 years. Further investigation with abdominal ultrasound and magnetic resonance imaging revealed a large pelvic mass (maximum diameter $>$ 11cm), of mixed consistency possibly originating from the left ovary. Synacthen test was normal. Complete surgical excision of the tumor was performed.
Results
Histopathological examination revealed a Juvenile granulosa cell tumor (JGCT) of the left ovary, TNM/UICC stage: pT1a. Further treatment was not required, as postoperative imaging with MRI and PET-scan had no abnormal findings. Furthermore, she had complete regression of breast tissue and pubic hair while hormonal levels were prepubertal, two months post-surgery.
Conclusions
JGCT is a rare tumor in children and adolescents and most of the cases with ovarian malignancy present in advanced-stage disease. The exact etiology is unknown, while in adults, mutations in FOXL2 have been identified as the key pathogenic factor. It is treated with surgical excision and adjuvant CMT in cases of advanced disease. The prognosis is excellent in lesions confined to the ovary. The differential diagnosis of peripheral precocious puberty includes functional ovarian cysts, granulosa cell tumors, gonadoblastomas, CAH, adrenal tumors, severe hypothyroidism, McCune Albright syndrome, and exposure to estrogens or endocrine disruptors. Early diagnosis is crucial for an optimal outcome.

Adrenocortical carcinoma with co-secretion of aldosterone and cortisol: a case report

Fatima Ezzahra Mennani[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition Mohammed VI University Hospital Marrakech Morocco, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition Mohammed VI University Hospital Marrakech Morocco, Marrakech, Morocco

Introduction
Adrenocortical carcinomas are epithelial malignant tumors arising in the cortical zone of the adrenal gland. They are extremely aggressive and very rare, with an incidence of 1 to 2 cases / year / million population and a prevalence of 4 to 12 cases per million population, in contrast to benign adrenal tumors, which account for 3% of the general population over the age of 50. These tumors have been divided into non-functional and functional tumors. We report a rare case of adrenocortical carcinoma with co-secretion of aldosterone and cortisol.
Case report
A 46-year-old patient referred to our department for etiological assessment of malignant hypertension for 8 years and severe hypokalemia. He presented with edema of the lower limbs and acanthosis nigricans. The aldosterone/renin ratio (ARR) was 381 pmol/mUI, indicating aldosterone excess. Dexamethasone minute braking was negative at 9.7mg/dl. Abdominal CT scan revealed a large, relatively well-limited, calcified left adrenal mass with heterogeneous enhancement, measuring approximately 63 x 86 x90 mm, with no other abdominal lesions. The patient underwent unilateral adrenalectomy, which resulted in a large, ovoid, firm, whitish-grey mass. Pathological examination with immunohistochemical complement was compatible with adrenocortical carcinoma, a Weiss score of 3. Postoperatively, the patient's blood pressure returned to normal and hypokalemia did not recur.
Discussion
Adrenocortical carcinoma is a rare malignancy. The clinical presentation is variable. Functional or secretory adrenocortical carcinomas cause an endocrine syndrome. In order of frequency, this may be isolated hypercorticism or hypercorticism associated with virilization or feminization, or primary hyperaldosteronism, as in the case of our patient. The literature confirms the rarity of exclusive aldosterone production by adrenocortical carcinoma. The diagnosis is made in the presence of signs of hormonal hypersecretion dependent on the hormone synthesis pathway developed by the tumoral endocrine tissue, or in the presence of a tumoral syndrome. Adrenal CT is the first-line examination for adrenal exploration in cases of hormonal hypersecretion syndrome. Surgery is the first-line treatment, whatever the type of secretion. In cases of recurrence where excision has been incomplete or rejected, the second-line treatment is mitotane alone or combined with chemotherapy. Adjuvant radiotherapy is not systematic, and is mainly used to treat secondary bone or brain damage.
Conclusion
This case illustrates the importance of a comprehensive hormonal evaluation of patients presenting with a picture of primary hyperaldosteronism with or without functional signs of hypercorticism, to diagnose these likely underestimated co-secretions.

When two cancers collide: a case of rectal adenocarcinoma following thyroid cancer

Manar Bari[1], Sana Rafi[1], Sara Ijdda[1], Ghizlane El Mghari Tabib[1] & Nawal El Ansari[1]
[1]Mohamed VI University Hospital Center VI, Department of Endocrinology, Marrakech, Morocco

Introduction
Thyroid cancer survivors, particularly those with papillary carcinoma, have an increased risk of developing a second primary cancer, including colorectal cancers. This heightened risk may be attributed to genetic, environmental factors, or prior treatments such as radioactive iodine therapy. We present the case of a patient who developed a lower rectal adenocarcinoma seven years after undergoing thyroidectomy for papillary carcinoma, highlighting the importance of vigilant surveillance in thyroid cancer survivors.
Case Report
A 43-year-old woman with no family history of cancer was diagnosed with papillary thyroid carcinoma in 2015, for which she underwent a total thyroidectomy followed by radioactive iodine therapy. In 2022, she presented with rectal symptoms, including rectal bleeding and tenesmus, leading to the diagnosis of a lower rectal adenocarcinoma. A colonoscopy confirmed the presence of a rectal tumor, and biopsy results showed a poorly differentiated, infiltrating adenocarcinoma. The patient underwent surgical resection followed by adjuvant chemotherapy and radiotherapy.

Discussion
This case highlights the increased risk of second primary cancers in survivors of thyroid cancer. Numerous studies have shown that patients with papillary thyroid carcinoma are at a higher risk for developing colorectal cancers. For instance, a meta-analysis by Berthe *et al*. reported an elevated risk of second primary cancers, including colorectal cancer, in these patients. Likewise, Rubino *et al*. observed a significant association between thyroid cancer and colorectal cancers. The underlying mechanisms could involve shared genetic mutations, hereditary syndromes, or side effects from radioactive iodine treatment.
Conclusion
Thyroid cancer survivors, particularly those with papillary carcinoma, should undergo close surveillance to detect second primary cancers, especially colorectal ones, at an early stage. Genetic evaluation and regular screening are crucial for these patients to ensure early detection and better outcomes.

Reabilitation of patients who was operate from the thyroid cancer
Yuriy Aleksandrov[1] & Artem Dyakiv[2]
[1]Yaroslavl State Medical Univercity, Surgery, Yaroslavl', Russian Federation; [2]Yaroslavl State Medical Univercity, Surgery, Yaroslavl, Russian Federation

Rehabilitation of patients with thyroid cancer includes medical, instrumental, psychological and social support. It begins with the establishment of a preliminary diagnosis (ultrasound, cytology, laboratory tests) and continues after surgery for the rest of the patient's life. All patients need to be monitored using the necessary studies aimed at detecting relapses and metastases, as well as medical support. We analyzed 1,382 cases (1,194 women, 186 men operated on for thyroid cancer in 1996-2021). The tumor prevalence corresponded to T1 and T2 (54% and 22%, respectively), the common forms - 24%. Metastatic lesion of the neck lymph nodes was observed in 331 (23.9%) patients, including patients with T1. The main type of surgery was thyroidectomy (74%), hemithyroidectomy - in 25% of cases (with T1), thyroid resection – in 1%. The main morphological form was papillary cancer (1272 patients; 92%). 5.8% of patients had postoperative complications. In 504 people (36.5%), radioiodine therapy was included in the complex of postoperative treatment. Repeated surgical intervention was performed in 134 patients (9.7%). All patients were prescribed medication therapy. When prescribing doses of L-thyroxine, the variants of the presence of genetic mutations in patients affecting the metabolism of the drug (the SLCO1B1 Val174Ala gene) were taken into account. After 13-28 years, 734 patients (53.1%) remain under observation. During the follow-up, 415 patients died from other causes (stroke, heart attack, covid-19, and others). 33 patients (2.4%) died of thyroid cancer. Some patients refused medical examination. To assess the effectiveness of suppressive therapy, TSH and thyroglobulin levels were determined in the blood. The group of patients with a good decrease in TSH levels (less than 0.1 IU/ml and thyroglobulin less than 1 ng/ml) was large (78.4%). 11.3% of patients had impaired L-thyroxine intake. Some patients (8.5%) (after hemithyroidectomy) did not undergo medical examination and refused L-thyroxine. In 19.4% of patients who did not take suppressive doses of L-thyroxine, signs of desymination were revealed. Clinical and laboratory manifestations of hypoparathyroidism were observed in 1.4% of patients. Research by psychologists has shown that the first six months after surgery are the most "difficult", it is at this time that "positive training", "life continuation training" is needed. In the future, the level of anxiety and "immersion in the disease" tended to decrease, which ensured good professional and social adaptation for more than 10 years.

Follicular thyroid carcinomas: epidemiological, clinical, and therapeutic profiles
Rachida Bouattay[1], Sabrina Farhani[1], Oumaima Ben Khalifa[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]ENT and Head and Neck Department, University Hospital of Fattouma Bourguiba, Monastir, Tunisia

Objectives
To study the epidemiological, clinical, anatomopathological, and therapeutic particularities of follicular thyroid carcinoma (FTC).
Patients and Methods
This is a retrospective study involving 20 patients treated for FTC over a period of 14 years.
Results
The average age was 49 years, with a female-to-male ratio of 5.66. The mode of discovery was a cervical mass in 17 cases, bone metastasis in 2 cases, and compression signs in 1 case. The average consultation delay was 16 months. Cervical ultrasound performed in all cases revealed thyroid nodules classified as EUTIRADS 3 (80%), EUTIRADS 4 (15%), and EUTIRADS 5 (5%). Fine needle aspiration was performed in 3 patients (15%). Surgery involved thyroid surgery in all cases, with central node dissection in 12 cases (60%) and selective lateral dissection in 1 case (5%). The frozen section examination was conducted for all patients, with benign results in 15 cases (75%) and malignant results in 5 cases (25%). Definitive histological examination confirmed the diagnosis of FTC in all cases. Staging for recurrence risk categorized the patients into 3 groups: low risk in 15 cases, intermediate risk in 1 case, and high risk in 4 cases. Ninety-five percent of patients received radioactive iodine therapy. Whole-body scanning revealed pulmonary metastases in 2 cases and bone metastasis in 2 cases. The average follow-up duration was 49.7 months.
Conclusion
FTC represents 10-15% of all thyroid carcinomas. It tends to metastasize more frequently to distant sites, particularly to the lungs and bones.

Background
Peptide receptor radionuclide therapy (PRRT) has shown promising activity in somatostatin receptor (SSTR)-positive lung neuroendocrine tumors (NETs) in retrospective series. This study aims to compare the efficacy, safety, and patient-reported outcomes of 177Lu-edotreotide versus the standard of care everolimus in patients with advanced lung and thymic NETs.
Methods
The LEVEL trial is a randomized, open-label, phase 3 international (France, Italy, Belgium, and Spain) trial evaluating 177Lu-edotreotide versus everolimus in patients with progressive, advanced, and well/moderately differentiated NETs of lung (typical/atypical) or thymic origin. Patients could be treatment naïve or have progressed (PD) on somatostatin analogues or up to 2 additional systemic treatments. Prior PRRT or mTOR inhibitors are not permitted. Eligible patients are randomly assigned 3:2 to 177Lu-edotreotide or everolimus. 177Lu-edotreotide is administered intravenously at a total dose of 7.5 ± 0.7 GBq per cycle for up to 6 cycles, with a 6-week interval between cycles 1 and 2 and a 8-week interval between cycles afterwards. Everolimus is administered orally 10 mg once daily until PD or unacceptable toxicity. CT or MRI scans are performed every 12 weeks until PD. Blood samples are analyzed at baseline, at 1st tumor assessment, and at PD for pharmacodynamic endpoints. Archival tumor tissue samples will be analyzed for ancillary studies. The primary endpoint is progression-free survival (PFS) according to RECIST v1.1. Secondary endpoints include overall response rate, overall survival, safety, and quality of life (EORTC QLQ-C30). The planned sample size is 120 patients using a two-sided Lan-DeMets with O'Brian-Fleming-like boundaries test to demonstrate a statistical significant reduction of PFS hazard ratio of 0.536 in favor of 177Lu-edotreotide ($\alpha = 0.05$, $\beta = 0.2$). The study includes an interim analysis after 60 PFS events are observed. The final analysis will be conducted after 87 PFS events. Recruitment started in Oct 2023. The study is active in all four countries. Currently, 57 patients have been randomized, and three more patients are in screening. Completion of recruitment is expected by the end of 2025. Clinical trial identification: EU CT: 2022-502154-13-00 / NCT05918302

Family matters! - a rare case of SDHB gene linked metastatic paraganglioma

Zehra Irshad[1], Dominic Oduro-donkor[1], Manoj Dodiya[1] & Martin O. Weickert[1]
[1]University Hospital Coventry and Warwickshire, WISDEM, Coventry, United Kingdom

Background
Paraganglioma is a rare catecholamine secreting neuroendocrine tumour commonly occurring in the head and neck. They are usually slow growing and can be associated with genetic syndromes 35% of the cases. Treatment depends on the size and location of the tumour and if completely excised can have good prognosis. However, once metastasised, rapid progression and poor prognosis are observed. Here, were describe a rare case of germline pathogenic succinate dehydrogenase subunit B (SDHB) gene linked metastatic paraganglioma.
Case
A 42-year-old gentleman came into Emergency Department after he fell from a chair. MRI showed a pathological C3 collapse with tumour infiltration and enlarged jugular chain lymphadenopathy. He also had high blood pressure and upon detailed history complained of multitude of intermittent symptoms which he had ignored in the last 6 months (including chest pain, palpitations, somnolence, feeling sweaty, double vision and pins and needles in left arm). Initial biopsy after anterior C3 corpectomy showed osseous hemangioblastoma. Further biopsy of lymphadenopathy showed strong expression of inhibin and positive chromogranin and synaptophysin. MIBG and 68Ga PET scan revealed extensive metastasis from skull base into the pelvis involving cervical spine, skull base, left scapula, bilateral ribs, pelvis, bilateral para-aortic soft tissue and left liver lobe. Subsequent immunohistochemistry showed- low Ki-67 index, 1-2%. Bloods tests showed low plasma metanephrines (174.2 pmol/l (reference <510pmol/l)) and significantly raised plasma normetanephrines (30,508 pmol/l (reference <1180 pmol/l)). He was thus diagnosed with metastatic paraganglioma and treated under Endocrinology, Oncology, Neurosurgery and Ophthalmology. Genetic testing was positive for SDHB gene which was also positive in five of his other eight siblings. He was treated symptomatically with alpha-blockers and beta blockers, and received palliative surgery (e.g., for skull base/brain involvement), together with systemic treatment including treatment with CAPTEM chemotherapy, radiotherapy, and lutetium PRRT. Unfortunately, he passed away within 4 years of diagnosis.
Discussion
Metastatic paragangliomas are rare and challenging to treat due to often late presentation based on initially non-specific symptoms, often rapid spread, and limited treatment options. Patients with SDHB gene mutations have increased risk of developing metastases and hence require, long-term surveillance. Early diagnosis is crucial to ensure optimum management. Metastatic disease can be managed with options like radiotherapy, radiofrequency, chemotherapy or molecular targeted therapies like PRRT. Multidisciplinary team approach is central to treatment given its complex nature.

Molecular and functional characterisation of the somatostatin system unravels novel vulnerabilities in hepatocellular carcinoma

Antonio García-Estrada[1,2,3], Natalia Hermán-Sánchez[1,2,3], Betsaida Ojeda-Pérez[1,2,3], Víctor J. Fernández-Ramírez[1,2,3], Amelie Lupp[4], Manuel Rodríguez-Perálvarez[1,5,6], Stefan Schulz[4,7], Raul M. Luque[1,2,3], Juan Luis López-Cánovas[1,2,3] & Manuel D. Gahete[1,2,3]
[1]Maimónides Biomedical Research Institute of Córdoba (IMIBIC), Córdoba, Spain; [2]University of Córdoba (UCO), Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]Reina Sofía University Hospital (HURS), Córdoba, Spain; [4]Friedrich-Schiller-University (FSU) Jena, Jena University Hospital, Institute of Pharmacology and Toxicology, Jena, Germany; [5]Reina Sofia University Hospital (HURS), Department of Hepatology and Liver Transplantation, Córdoba, Spain; [6]University of Córdoba (UCO), Department of Medical and Surgical Sciences, Córdoba, Spain; [7]7TM Antibodies GmbH, Jena, Germany

Liver cancer is the sixth most incident and third most lethal cancer type worldwide. Among its subtypes, hepatocellular carcinoma (HCC) is predominant, comprising 90% of the cases. The overall 5-year survival rate of HCC patients is still extremely low (20%), partially due to a high intra- and intertumoral heterogeneity that severely complicates systemic treatment (first line: immunotherapy, second line: tyrosine kinase inhibitors). Despite its known role as a (neuro)endocrine hub, classic (neuro)endocrine tumour profiling and approaches [i.e., somatostatin (SST) system receptor expression and ligand response] have been poorly explored in HCC, with limited and inconclusive results. For this reason, this study aimed to obtain a molecular and functional description of the SST system in HCC. To achieve this, we used 2 internal retrospective cohorts [Retrospective-1 (R1): HCC vs. non-tumoral adjacent tissue (NTAT) ($n = 93$); Retrospective-2 (R2): HCC vs. NTAT ($n = 58$), cirrhotic ($n = 39$) and healthy liver tissue ($n = 5$)], 6 in silico cohorts [GSE6764 ($n = 65$), GSE14323 ($n = 107$), GSE14520 ($n = 247$), GSE164760 ($n = 141$), CPTAC-PDC000198 ($n = 165$), TCGA-LIHC ($n = 369$)] and 4 human liver cell lines [healthy hepatocytes (THLE-2), hepatoblastoma (HepG2) and HCC (Hep3B, SNU-387)]. SST receptor (SSTR1-5) and ligand (SST, CST) expression was assessed by RT-qPCR (all models) and immunohistochemistry [IHC, subset ($n = 25$) of R1]. Cell lines were also employed to evaluate the expression of key neuroendocrine markers and SST receptor (SSTR) downstream effectors, in addition to their functional response to SSTRs natural ligands, classic analogues (octreotide, lanreotide, pasireotide) and novel agonists (BIM-23926, BIM-23120) by different *in vitro* assays (proliferation, colony and hepatosphere formation). HCC patient samples were characterised by a general SST system expression downregulation, which was linked to complex patterns of tumour aggressiveness through clinical variables (e.g., survival, recurrence, microvascular invasion and portal hypertension) and complemented by IHC staining results [positiveness of infiltrating immune cells (SSTR1, SSTR2) and vascular endothelia (SSTR5)]. Cell lines mimicked this expression pattern, where the highest SSTR expression was found in low (HepG2) and intermediate (Hep3B) aggressiveness liver cancer cells. Accordingly, antitumoral effects were observed among the different *in vitro* assays for octreotide, pasireotide, BIM-23926 and BIM-23120 in HepG2; all ligands except

SST in Hep3B and SST and CST in SNU-387. These results could be explained through biased signalling by specific neuroendocrine markers and SSTR-downstream effectors profiles (e.g., CDH1 in Hep3B, AIP in SNU-387). In conclusion, our data suggests that the SST system is an intricate, yet exploitable source of informative biomarkers and individualised therapeutic options in HCC.

JOINT2465

A case of long-standing pituitary macroadenoma leading to panhypopituitarism and visual impairment

Ia Kavtiashvili[1], Natia Margvelashvili[1] & Mariam Bulashvili[1]
[1]Tbilisi Institute of Medicine, Tbilisi, Georgia

Introduction

Internationally, panhypopituitarism has an estimated incidence of 4.2 cases per 100,000 per year. Hypopituitarism may present as a deficiency of individual anterior or posterior pituitary hormones or as a complete deficiency of all pituitary hormones, known as panhypopituitarism. We present a case of a 67-year-old male with a long-standing macroadenoma, previously treated as a prolactinoma, complicated by anterior pituitary hormonal deficiency.

Case report

A 67-year-old male was diagnosed with a prolactinoma nine years ago and was started on cabergoline (0.5 mg, half a pill twice weekly). Upon admission to our hospital in 2024, he presented with progressively worsening blurred vision, fatigue, low energy, and hypotension. Given his deteriorating symptoms, cabergoline was discontinued, and a comprehensive endocrine evaluation, along with magnetic resonance tomography (MRT), was performed. Imaging revealed a 48 mm pituitary macroadenoma compressing the optic chiasm, explaining the patient's worsening vision. Laboratory tests confirmed secondary adrenal insufficiency and secondary hypothyroidism. The patient was started on hydrocortisone and levothyroxine to manage his endocrine deficiencies. Following stabilization, he underwent transsphenoidal pituitary macroadenoma resection in July 2024. Postoperatively, his symptoms significantly improved, except for persistent visual impairment. At a follow-up visit after surgery, the patient reported drowsiness. Laboratory tests revealed that his Free T4 levels were within the lower normal range, prompting an increase in the levothyroxine dosage. Following this adjustment, the patient experienced symptomatic improvement.

Conclusion

This case highlights the importance of regular endocrine reassessment in patients with pituitary adenomas. Early recognition and management of secondary endocrine deficiencies are essential for optimizing patient outcomes, as untreated deficiencies can lead to severe complications and even death. Although surgery successfully resolved most symptoms, persistent visual impairment underscores the need for timely intervention in pituitary macroadenomas.

A case of severe hyponatremia due to SIAD likely caused by uterine sarcoma

Yoshihisa Sugimura[1], Keiko Okamoto[1], Shogo Nakayama[1], Haruki Fujisawa[2], Kaori Ushida[3], Fumi Utsumi[4], Makoto Urano[5], Naoya Asai[3], Kiyosumi Shibata[4] & Atsushi Suzuki[2]
[1]Fujita Health University Bantane Hospital, Department of Endocrinology, Diabetes and Metabolism, Nagoya, Japan; [2]Fujita Health University, Department of Endocrinology, Diabetes and Metabolism, Toyoake, Japan; [3]Fujita Health University, Department of Pathology, Toyoake, Japan; [4]Fujita Health University Bantane Hospital, Department of Obstetrics and Gynecology, Nagoya, Japan; [5]Fujita Health University Bantane Hospital, Department of Pathology, Nagoya, Japan

Case

A 78-year-old woman presented with abnormal uterine bleeding. Endometrial biopsy revealed findings suggestive of a sarcoma. Upon there were no obvious signs of dehydration or edema. Without intravenous fluids, laboratory findings were as follows: serum Na 125 mEq/l, plasma vasopressin concentration 2.4 pg/mL, plasma osmolality 257 mOsm/kg, urine osmolality 354 mOsm/kg, urinary Na 101 mEq/l, plasma renin activity 0.6 ng/mL/hr, and serum uric acid 2.7 mg/dL. Given normal renal and adrenal cortical function, a diagnosis of syndrome of inappropriate antidiuresis (SIAD) was made. Fluid restriction was implemented along with intermittent administration of hypertonic saline. On hospital day 4, treatment was switched to oral NaCl, but even with NaCl administration of 12 g/day, serum Na did not increase sufficiently. Hypertonic saline was continued until serum Na reached 130 mEq/l. By hospital day 8, serum Na improved to 137 mEq/l, and a hysterectomy with bilateral salpingo-oophorectomy was performed while maintaining serum Na levels with a continuous infusion of approximately 1.5% hypertonic saline. Pathological examination revealed undifferentiated uterine sarcoma and endometrioid carcinoma. After surgery, hypertonic saline administration became unnecessary, plasma vasopressin concentration decreased to around 1.0 pg/mL, and serum Na stabilized in the 130 mEq/l range. The patient was discharged on oral NaCl 3 g/day. AVP immunostaining was performed on the tumor tissue, revealing AVP expression in some undifferentiated areas of the uterine sarcoma. AVP was not detected in the endometrioid carcinoma.

Discussion

Based on the clinical course and immunohistochemical findings, this case was considered SIAD caused by an ectopic vasopressin-producing tumor associated with uterine sarcoma. The causes of SIAD include central nervous system disorders, pulmonary diseases, ectopic vasopressin-producing tumors, and medications. Among ectopic vasopressin-producing tumors, small cell lung cancer is the most frequently reported and is well known for secreting AVP. The association between SIAD and gynecologic malignancies is rare. A literature search for cases of uterine sarcoma or endometrioid carcinoma associated with hyponatremia or SIAD identified only case reports of SIAD occurring during cisplatin-based treatment, with no other reported cases.

Conclusion

This case suggests a potential new etiology of SIAD associated with gynecologic malignancies and highlights its clinical significance.

Primary adrenal insufficiency secondary to bilateral adrenal metastasis of a prostatic adenocarcinoma: a case report

Meryam Alahyane[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakesh, Morocco, Marrakesh, Morocco

Introduction and Background

Prostate cancer, a leading malignancy in men, predominantly metastasizes to the bone and lymph nodes. Adrenal metastases are rare, with bilateral involvement being exceptionally uncommon and signaling advanced disease.

Case Report

We report a case of a 62-year-old chronic smoker presented with progressive obstructive urinary symptoms and gross hematuria. His PSA level was 183 ng/mL, and prostate biopsy confirmed adenocarcinoma. He underwent prostatectomy and bilateral castration, revealing moderately differentiated, infiltrative adenocarcinoma (Gleason 8, ISUP grade 4) with perineural invasion. After a three-year lapse in follow-up, he returned with gastrointestinal symptoms, profound asthenia, hypotension, and generalized melanoderma. Acute adrenal insufficiency was diagnosed (cortisol 3.7 µg/dL, hyponatremia 113 mmol/l) and treated with hydrocortisone replacement and rehydration. Imaging identified bilateral adrenal masses (81 × 52 × 72 mm and 79 × 45 × 78 mm) with necrotic centers spontaneous density of 35 HU, and an absolute washout of 66%. Normal urinary metanephrines excluded pheochromocytoma. PSA had risen to 600 ng/mL, and MRI revealed recurrent prostate tumor with seminal vesicle infiltration and bone metastases. Given the advanced disease and imaging findings, adrenal biopsy was avoided, and the adrenal lesions were attributed to metastatic prostate adenocarcinoma.. Management included Docetaxel-based chemotherapy and hydrocortisone replacement (30 mg/day).

Discussion
Adrenal metastases from prostate cancer occur in 17–20% of cases in autopsy studies, with bilateral cases being particularly rare. Prostate cancer's preference for bone and lymph nodes is mediated by adhesion molecules and growth factors favoring these sites, while the adrenal gland's unique microenvironment may deter colonization. Hematogenous spread, however, can involve the adrenal glands in advanced stages. These metastases are often asymptomatic due to the adrenal glands' functional reserve, with insufficiency manifesting only after more than 90% cortical destruction. While bilateral adrenalectomy may be an option in select cases, non-surgical treatments, such as chemotherapy, are generally preferred to reduce both primary and metastatic tumors. Chemotherapy may preserve the potential for adrenal function recovery, though definitive evidence on reversibility is limited.
Conclusion
Bilateral adrenal metastases in prostate cancer highlight the complexity of metastatic behavior in advanced disease. Comprehensive imaging and biochemical evaluations are essential in symptomatic cases. Research into adrenal microenvironment interactions and steroid biosynthesis pathways in prostate cancer may improve our understanding of metastatic patterns and guide innovative therapies.

When secondary localizations reveal papillary thyroid carcinoma: a case report

Ghita Khamel[1], Nada Aitkassi[1], Ghizlane Sabbar[1], Kawtar Rifai[1], Hind Iraqi[1] & Mohamed Hassan Gharbi[1]
[1]CHU Ibn Sina, Rabat, Morocco

Introduction
Papillary thyroid carcinoma is the most common histological type of thyroid cancer. Its spread is essentially lymphatic. Its prognosis is generally very good, and metastases are rare. We will illustrate a case of a patient with papillary carcinoma revealed by metastatic localization.
Observation
This 86-year-old patient presented with an altered general condition and persistent cough. A cervico-thoracic CT scan was performed, revealing multiple secondary pulmonary balloon lesions and a suspicious hepatic nodule. Clinical examination revealed a fixed, hard 2 cm cervical swelling. Cervical ultrasound revealed several eutirad nodules 3 and 5 associated with a highly suspicious laterocervical adenopathy. A total thyroidectomy with lymph node dissection was performed, and pathological examination revealed an infiltrating papillary carcinoma with vascular emboli.
Discussion
Papillary thyroid carcinoma (PTC) is the most common type of thyroid cancer, accounting for around 70-80% of cases. This cancer is generally well-differentiated and has a good prognosis, with high long-term survival. However, in some cases, it may be discovered atypically. Differentiated thyroid carcinomas rarely metastasize. Papillary thyroid carcinoma has a well-known tendency to spread to cervical lymph nodes, particularly in the jugular and supraclavicular areas. However, distant dissemination to other organs is less frequent. Distant localization is mainly to the lungs and bones. The standard treatment for distant metastases remains surgery, particularly if the metastases are limited and accessible. However, chemotherapy or radiotherapy may be necessary for more advanced cases or those where surgery is not possible. Treatment consists of total thyroidectomy with lymph node dissection. Adjuvant treatments, such as radioactive iodine (I-131), are also used in cases where the cancer remains differentiated and can accumulate iodine. The prognosis of patients with metastatic disease from papillary thyroid carcinoma is generally favourable, especially if the metastases are limited and accessible. However, in the most aggressive forms with diffuse metastases, the prognosis is less favourable.
Conclusions
Papillary thyroid carcinomas revealed by metastases are rare but present a major diagnostic and therapeutic challenge.

Gastrinoma and zollinger ellison syndrome: a management roadmap

Alexandra Balasa[1], Ramona Dobre[1,2], Iulia Burcea[1,2], Andreea Brinzan[1], Madalina Sorohan[1,2] & Catalina Poiana[1,2]
[1]Ci "Parhon" National Institute of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background
The terms gastrinoma and Zollinger-Ellison syndrome (ZES) have been frequently used as synonymous. However, gastrinomas are neuroendocrine tumors that secrete gastrin, whereas ZES refers to the clinical manifestations produced by hypergastrinemia.
Material and methods
We aimed to analyze the characteristics of patients diagnosed with gastrinomas. Between 2018 and 2024, 6 patients were diagnosed with gastrinomas in our center. They were evaluated based on clinically significant symptoms, serum gastrin level, neuroendocrine markers and with the aid of imaging such as abdominal CT or MRI, EUS, Tektrotyd scintigraphy and had genetic counseling and were tested for inherited genetic syndromes. Surgery was performed according to the localization of the tumors.
Results
Six patients with a gastrinoma diagnosis were included, four out of which had ZES. The patients had a mean age of 59 years, 50% were women, with an average BMI of 30.51 kg/m2. At diagnosis, the median level of gastrin was 292 pg/ml and all of the patients had abdominal pain, 66.67% weight loss, 50% diarrhea and one had upper gastrointestinal bleed. Most common sites of lesion were gastric and duodenal (33% each) followed by pancreatic site and one patient had no evidence of primary tumor. Five patients underwent surgical treatment with histological confirmation and had controlled neuroendocrine markers and gastrin levels after surgical treatment, while the sixth had an unknown primary lesion. Two patients (33%) have metastasis: mesenteric and pancreatic and no patient has an inherited genetic syndrome. All patients were controlled with long-acting somatostatin analogues and proton pump inhibitors.
Conclusions
Gastrinoma diagnosis is quite challenging as its symptoms can frequently be nonspecific. Two thirds of the patients evaluated in our center with a diagnosis of gastrinoma had ZES. Weight loss and other gastrointestinal manifestations were almost as frequent and a third had metastasis.

Anatomopathological characteristics of papillary thyroid carcinomas associated with autoimmune thyroid disease

Amira Bouchenna[1], Abdelghani Tibouk[1], Brahim Ghennam[1], Katia Benabdelatif[1], Ali Haddadi[1], Medjaher Meriem[1] & Meriem Bensalah[1]
[1]Central Hospital of Army Algiers, Algiers, Algeria

Introduction
The association between papillary thyroid carcinoma and thyroiditis was first reported in 1955 by Daily, in 2023 if this association is well established, it still continues to be talked about. Does cancer associated with thyroiditis have a better prognosis?
Material and Methods
We report a prospective study carried out in a hospital center in Algeria between 2020 and 2023 which included 267 papillary thyroid cancers, of which 97 (36.3%) patients had thyroiditis. 85 (87.6%) of the patients who had an association with thyroiditis were women with a sex ratio of 3.29; their mean age was 42.79 $\pm$ 1.16 years. In thyroiditis, tumor size was smaller (OR 0.51), with less vascular invasion (OR 0.39) but more multifocality (OR 1.75), with no statistically significant difference in thyroid invasion and lymph node metastases compared to patients without thyroiditis.
Discussion
The association of papillary thyroid cancer with thyroiditis has generated many studies worldwide, but it is difficult to make comparisons because of their heterogeneity; however, our study seems to be in agreement with the results obtained by a majority of studies already published.

Conclusion
The association of papillary thyroid cancer with thyroiditis seems to be a factor of better prognosis.

JOINT728

Effective treatment of metastatic insulinoma in MEN-1 syndrom with pasireotide

Pavel Cee[1], Jan Drugda[1], Jan Cap[1] & Filip Gabalec[1]
[1]University Hospital Hradec Kralove, 4th Department of Internal Medicine–Hematology, Hradec Kralove, Czech Republic

Introduction
Insulinoma is a rare endocrine tumor originating from the beta cells of the pancreas, characterized by excessive insulin secretion and resultant hypoglycemia. While most insulinomas are benign and localized, approximately 10% progress to metastatic disease. The management of insulinoma often involves a multimodal approach. Surgical resection remains the first-line treatment, however, for metastatic cases, somatostatin analogs such as lanreotide and pasireotide are increasingly employed to control insulin secretion and tumor progression
Case
We present a case of a 58-year-old woman with MEN1 syndrome, diagnosed in 1994. The patient underwent repeated parathyroidectomy for parathyroid hyperplasia. In 1994, two-thirds of the pancreas were resected, and in 2012, an adenoma in the head of pancreas was enucleated due to the discovery of an insulinoma. The prolactinoma of the pituitary gland was managed with conservative treatment. In 2020, multiple liver lesions were found, along with recurring episodes of hypoglycemia. The presumed diagnosis was insulinoma metastases, but the lesions were not detected on the Octreoscan, which seemed to contradict the presumed diagnosis. Histological analysis of a biopsy from the dominant liver lesion confirmed a neuroendocrine tumor. Receptor testing revealed positivity for SSTR5 but negativity for SSTR2, explaining the negative Octreoscan findings. In 2022, microwave ablation was performed on the largest liver lesion. After that, the treatment with somatostatin analogues was initiated. The patient was first treated with lanreotide (pasireotide was not approved by insurance company). However, it did not adequately control the insulin secretion and episodes of hypoglycemia still occurred. Subsequently, therapy was switched to pasireotide, which effectively resolved the hypoglycemia. Pasireotide, with its high affinity for SSTR5, exerts potent antisecretory and antiproliferative effects, aligning well with the tumor's receptor profile.
Conclusion
This case highlights the complexities of managing metastatic insulinoma in the context of MEN1 syndrome. It underscores the importance of individualized treatment strategies, including receptor profiling, to guide therapy selection. While lanreotide proved ineffective, the use of pasireotide successfully controlled the patient's hypoglycemia, emphasizing the value of alternative somatostatin analogs for SSTR5-positive tumors. The multidisciplinary approach, including surgical interventions, receptor testing, and tailored medical therapy, was crucial in achieving symptom control and improving the patient's quality of life.

Late endocrine disorders in surviving children with acute lymphoblastic leukemia: single center study in Egypt

Doaa Khater[1,2], Farah Ahmed[1] & Shaimaa Raafat[2]
[1]Alexandria University, Alexandria, Egypt; [2]Alexandria University Egypt, Alexandria, Egypt

Background
Acute lymphoblastic leukemia (ALL) is the most prevalent cancer diagnosed in pediatric population. After treatment and subsequent follow- up, most children and adolescents affected by ALL are able to resume their normal routines. However, survivors of childhood cancer require careful ongoing monitoring, as the side effects of cancer therapies may emerge years following the treatment especially the endocrine disorders and its effect on growth, puberty, thyroid gland and gonadal development.
Aim
To estimate the probability of late endocrine disorders in children who received chemotherapy during their treatment for ALL at Borg El-Arab University Pediatric Oncology Hospital, Egypt & to assess the anthropometric measurements and pubertal staging and determine the risk factors for development of endocrine disorders in these children
Results
The study included 146 participants, with 73 survivors of ALL and 73 healthy controls. According to height, survivors exhibited a significantly reduced mean height (129.5 $\pm$ 18.31 cm) compared to controls (136.2 $\pm$ 22.51 cm; $t=1.974$, $P=0.050$). The majority of patients had normal TSH levels with elevated TSH observed in 7.7% of cases indicating subclinical hypothyroidism. Elevated TSH was more prevalent in the short stature group (33.3%) compared to the overweight and obese group (7.4%), 89.7% of patients had normal glucose level, while 10.3% were classified as prediabetic, who were overweight/obese group. Both groups demonstrated normal ACTH and cortisol levels Conclusion: Endocrine disorders are very common among ALL survivors and need close monitoring and prompt treatment if detected early.

Unveiling hidden hyperparathyroidism: the critical role of calcium and PTH measurement in early diagnosis

Tamar Peshkova[1], Koba Kamashidze[2], Liana Jashi[3] & Irina Nakashidze[1]
[1]Batumi Shota Rustaveli State University, Batumi, Georgia; [2]University of Georgia, Tbilisi, Georgia; [3]Avicenna - Batumi Medical University, Batumi, Georgia

Background
Primary hyperparathyroidism (PHPT) is an underdiagnosed condition with systemic consequences, including cardiovascular disease, nephrolithiasis, and osteoporosis. Routine calcium and parathyroid hormone (PTH) measurement is crucial for early detection. Additionally, ultrasonography plays a key role in localizing parathyroid adenomas. We present three cases highlighting the consequences of delayed diagnosis and the importance of endocrine evaluation.
Case Presentation: Case 1
A 64-year-old female presented for levothyroxine dose adjustment. Neck ultrasound revealed a suspicious adenoma, confirmed by scintigraphy. Laboratory findings showed elevated PTH (310 pg/mL), hypercalcemia, and vitamin D deficiency (18 ng/mL). She had osteoporosis and a significant cardiovascular history, including an aortocoronary bypass and cryoablation for arrhythmias eight years prior. Despite these events, hyperparathyroidism was never suspected, highlighting the potential cardiovascular impact of undiagnosed PHPT.
Case 2
A 57-year-old female with recurrent nephrocalcinosis and multiple ureteral stents due to complications over five years was diagnosed with PHPT. PTH was 160 pg/mL, calcium was elevated, and scintigraphy confirmed an adenoma. She also had osteoporosis, previously misattributed to aging. Earlier diagnosis could have prevented renal and skeletal complications.
Case 3
A female with newly diagnosed Graves' disease underwent ultrasound, which incidentally revealed a suspicious parathyroid adenoma. Biochemical workup confirmed PHPT with hypercalcemia, and scintigraphy validated the diagnosis. The coexistence of Graves' disease and PHPT highlights the need for careful endocrine assessment. All patients underwent successful parathyroidectomy, leading to normalization of PTH levels and resolution of hypercalcemia.
Discussion
These cases emphasize PHPT's systemic effects and its frequent underrecognition in patients with cardiovascular disease, nephrolithiasis, and osteoporosis. The first case underscores PHPT's potential role in cardiovascular pathology, while the first two cases highlight its impact on bone health. The third case illustrates the importance of evaluating parathyroid glands during thyroid ultrasound. Routine screening for hyperparathyroidism in high-risk patients can prevent severe complications.
Conclusion
PHPT should be considered in patients with unexplained cardiovascular disease, recurrent nephrolithiasis, and osteoporosis. Routine calcium and PTH measurement, alongside careful ultrasound evaluation, is crucial for early detection. Recognizing PHPT at an early stage can significantly improve patient outcomes.

The impact of metabolic syndrome on survival outcomes in urothelial carcinoma: a retrospective cohort study

Aspasia Manta[1], Afroditi Roumpou[1], Maria Gerogianni[1], Roubini Zakopoulou[2], Kimon Tzannis[2], Areti Mamali[2], Vasiliki Malamatini[2], Konstantina Kakogianni[2], Aristotelis Bamias[2] & Melpomeni Peppa[1,3]
[1]Attikon University Hospital, Endocrine Unit, Second Propaedeutic Department of Internal Medicine, Research Institute and Diabetes Center, Athens, Greece; [2]Attikon University Hospital, Second Propaedeutic Department of Internal Medicine, Research Institute and Diabetes Center, Athens, Greece; [3]Sotiria General Hospital for Chest Diseases, Third Department of Internal Medicine, Athens, Greece

Urothelial carcinoma (UC) is a prevalent malignancy of the urinary system. Muscle-invasive UC is associated with significant morbidity and mortality. Metabolic syndrome (MetS), characterized by a combination of obesity, hypertension, dyslipidemia, and insulin resistance, has been implicated in various cancers, including UC. However, its impact on UC prognosis remains underexplored. This study aims to assess the association between MetS and survival outcomes in UC patients. A single-center retrospective study was conducted, analyzing 112 patients with histologically confirmed UC, diagnosed between January 2018 and February 2024. Patients were categorized based on the presence of MetS ($\geq$ 3 criteria) or its individual components. Survival outcomes, including overall survival (OS) and progression-free survival (PFS), were evaluated using Kaplan–Meier estimates and Cox proportional hazard regression models, adjusting for disease stage and other covariates. Of the 112 patients (82.1% males, with a median age at diagnosis of 71.9 years [IQR 65.8-79]), 49 (43.8%) met the criteria for MetS. In a multivariable analysis, patients with MetS exhibited significantly worse OS and PFS compared to those without MetS (HR: 2.04, 95% CI 1.13-3.68, $P = .018$; HR: 2.13, 95% CI 1.11-4.1, $P = .024$, respectively), after adjusting for disease stage and other covariates. Among individual MetS components, diabetes had the strongest association with reduced survival (HR: 3.33, 95% CI 1.59-6.98, $P = .001$ for OS). Hypertension also emerged as an independent predictor of poor OS (HR: 1.96, 95% CI 1.04-3.73, $P = .039$). MetS and its components, particularly diabetes and hypertension, are associated with poorer survival outcomes in UC patients. These findings highlight the need for integrating metabolic health management into UC treatment strategies to improve patient outcomes.

JOINT1888

Asymptomatic insulinoma diagnosed following a motor vehicle accident: a case report

Arowa Abdelgadir[1] & Jimmy Li Voon Chong[2]
[1]Royal Hampshire County Hospital, Endocrine and Diabetes, Winchester, United Kingdom; [2]Royal Hampshire County Hospital, Diabetes and Endocrinology, Winchester, United Kingdom

Insulinomas are rare pancreatic neuroendocrine tumors characterized by excessive insulin production, which leads to recurrent episodes of hypoglycemia. While most patients exhibit typical symptoms such as confusion and diaphoresis, a subset may experience hypoglycemia unawareness. This condition arises when repeated episodes of low blood glucose levels impair the body's autonomic responses, hindering the patient's ability to recognize early warning signs of impending hypoglycemia. Consequently, this can lead to delayed diagnoses and heightened risk of severe complications, including seizures, coma, or accidents. We present the case of a 69-year-old male diagnosed with insulinoma following a motor vehicle accident that revealed an alarming blood glucose level of 2.8 mmol/l, despite the patient reporting no symptoms. Subsequent investigations, including a supervised 72-hour fast, demonstrated inappropriately elevated C-peptide levels (1350 pmol/l) and insulin levels (14 mU/l) with a lab glucose reading of 2.2 mmol/l. A CT scan of the pancreas identified a 1.25 cm enhancing lesion in the proximal body, consistent with insulinoma. The patient successfully underwent a Whipple procedure, and his postoperative recovery was uneventful. This case highlights the diagnostic challenges associated with insulinomas, particularly in patients who exhibit hypoglycemia unawareness. It emphasizes the importance of considering insulinoma in the differential diagnosis for patients presenting with hypoglycemia unawareness. Early recognition and intervention are crucial to prevent serious complications associated with this condition.

A lung cancer patient presenting with gynecomastia and mastodynia secondary to paraneoplastic hyperestrogenism

Najoua Lassoued[1], Adem Kheder[1], Nada Hassairi[1], Houcem Elomma Mrabet[1], Alaya Wafa[1] & Zantour Baha[1]
[1]Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Introduction
Gynecomastia is a common clinical phenomenon that can result from various etiologies. Although it is generally linked to hormonal imbalances, gynecomastia can sometimes be associated with less obvious causes, such as paraneoplastic disorders. We report the case of a patient who presented with painful gynecomastia related to paraneoplastic hyperestrogenism.
Case presentation
A 68-year-old male patient was referred to the Endocrinology Department for painful gynecomastia that had been evolving for one year. He gives a history of lung adenocarcinoma, classified as T4N0M0, and he was undergoing chemotherapy with four cycles of Navelbine and Cisplatin. Hormonal testing showed marked hyperestrogenism, with normal levels of FSH, LH, testosterone, prolactin and β-HCG. The course of the condition was marked by the persistence of painful gynecomastia and persistent hyperestrogenism despite analgesic treatment and cessation of chemotherapy.
Discussion and conclusions
This case highlights the importance of investigating all possible causes of gynecomastia, including drug-related causes such as chemotherapy agents. Our patient had received Cisplatin and Navelbine, the adverse effect of which could be painful gynecomastia, but the symptoms persisted even after stopping chemotherapy. Patients with lung cancer and gynecomastia as a paraneoplastic syndrome have a frequency of approximately 2.4%. Gynecomastia is usually caused by an increased estrogen/androgen ratio, elevated serum levels of b-HCG, or an elevated level of prolactin. Our patient had a normal b HCG, a normal prolactin level, and a very high estrogen level which argues in favor of paraneoplastic hyperestrogenism.

Humeral metastasis of papillary thyroid carcinoma: a rare localisation in a case report

Doaa El Bazi[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Chadli Asma[1]
[1]UHC Ibn Rochd, Department of Endocrinology, Metabolic Diseases and Nutrition, Casablanca, Morocco

Introduction
Papillary thyroid cancer accounts for over 85% of thyroid cancers. About 3.9% of these cancers develop bone metastases. Humeral metastases are rare and exceptional.
Observation
A 57-year-old female patient underwent total thyroidectomy in 2022. Histopathological examination revealed a 9cm, poorly defined, left toto-lobar papillary carcinoma with vascular emboli and no capsular effraction. Post operative iratherapy at a dose of 100mCi was indicated, with a huge cervical residue on whole-body scan. The extension work-up revealed bone metastases at C6 and D1, with pulmonary metastases in the form of scattered pulmonary nodules, the largest of which was 19mm mediobasal on the left and 13mm posterobasal on the right. The patient underwent external radiotherapy (8Gy) for decompressive purposes, followed by sorafenib 800mg/day. Three months later, the patient presented with mechanical pain in the left humerus radiating to the left shoulder. A CT scan showed a heterogeneous hypodense mass measuring 61x56x80mm in the neck and proximal third of the humeral diaphysis, with necrotic aeras containing fluid. Bone scintigraphy confirmed metastatic lesions in the left humerus. The patient benefited from placement of a centromedullary nail with simple postoperative follow-up.
Discussion and conclusion
Bone metastases secondary to thyroid cancer are uncommon, but a rigorous clinical history and careful examination are essential for their early detection. The humerus is one of the extremely rare sites of metastatic spread. Conventional surgical approaches for humeral metastases include the use of centromedullary nails, our patient's case, plate fixation and augmentation with cement to reconstruct large bone defects.

Phenotypic diversity in patients carrying the Y791F RET proto-oncogene mutation

Dusan Ilic[1], Sanja Ognjanovic[1], Valentina Elezovic Kovacevic[1], Bojana Popovic[1], Milica Opalic Palibrk[1], Lena Radic[1], Katarina Krstic[1] & Djuro Macut[1]
[1]Clinic for endocrinology diabetes and metabolic diseses, University Clinical centre of Serbia, Belgrade, Serbia

The Y791F mutation of the *RET* proto-oncogene is a well-documented genetic alteration associated with familial medullary thyroid carcinoma (FMTC), multiple endocrine neoplasia type 2A (MEN2A), and familial pheochromocytoma. This mutation activates the *RET* receptor in its monomeric form. Here, we present an analysis of 15 unrelated families carrying the Y791F mutation, exhibiting diverse phenotypic expressions.

Patients and Methods

Over the past 35 years, we have evaluated 406 patients with medullary thyroid carcinoma (MTC) (age range: 2–80 years, mean age: 49 years). Genetic testing for *RET* proto-oncogene mutations was performed using direct double-strand sequencing of PCR-amplified genomic DNA.

Results

Of the 406 MTC cases, 128 (32%) were familial. Germline Y791F mutations (C791) were identified in eight patients with MTC (age at diagnosis: 33–62 years, mean: 48 years), all of whom were index cases within their families. Among these, four patients were diagnosed, surgically treated, and cured at ages 33, 42, 54, and 55, while four others presented with metastatic MTC at ages 47, 53, 54, and 62. One patient diagnosed at 53 years of age succumbed to the disease at 63. None exhibited associated disorders. The same mutation was identified in 33 family members. Prophylactic thyroidectomy was performed in five individuals, with histopathological confirmation of C-cell hyperplasia in three cases (ages 13, 16, and 29). One patient had concurrent kidney hypoplasia and primary hyperparathyroidism (PHPT), though MEN1 mutations were not detected. Two mutation carriers showed no clinical or histological evidence of thyroid disease. Additionally, six patients exhibited congenital urogenital anomalies without other associated conditions. The L769L polymorphism was detected in five individuals, including four with MTC.

Conclusion

The prevalence of inherited MTC in our cohort aligns with previous reports; however, the frequency of the Y791F mutation appears higher than in other studies. Phenotypic expression varies widely, ranging from asymptomatic carriers to overt malignancy. Notably, a more aggressive disease course was observed in patients harboring the coexistent L769L polymorphism. The presence of renal malformations suggests that despite its oncogenic potential, insufficient *RET* protein expression during embryogenesis may contribute to developmental anomalies or indicate the involvement of additional genetic factors.

Association of schmidt syndrome with papillary thyroid carcinoma

Imen Mhiri[1], Yesmine Elloumi[2], Fatma Chaltout[1], Ghada Mani[1], Mohamed Maaloul[1], Salma Charfeddine[1], Issam Jardak[1], Fatma Hamza[1] & Khalil Chtourou[1]
[1]Habib Bourguiba Univesity Hospital, Nulcear Medicine Department, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background

Papillary thyroid carcinoma (PTC) is the most common endocrine malignancy. The occurrence of PTC in patients with Hashimoto's thyroiditis (HT) has been reported and a debatable explanation of the association was some common dysregulated non-immune-linked genes involved in DNA damage and repair. However, the link between PTC and autoimmune polyglandular syndromes, such as Schmidt syndrome, has been rarely described, making it an intriguing subject for further investigation.

Case report

We report the case of a 47-year-old female with a history of Addison's disease who presented with a cervical nodule that appeared suspicious on ultrasound. Fine-needle aspiration biopsy confirmed the presence of papillary thyroid carcinoma. Histopathological examination not only validated the diagnosis of differentiated thyroid carcinoma but also revealed lymphocytic thyroiditis. Laboratory investigations showed elevated anti-thyroglobulin antibodies (56 IU/mL; normal <30 IU/mL) and elevated anti-thyroid peroxidase (TPO) antibodies, with undetectable thyroglobulin levels (<0.04 ng/mL) and high TSH levels. The patient underwent total thyroidectomy, followed by radioactive iodine therapy.

Conclusion

This case highlights the rare association between Schmidt syndrome and papillary thyroid carcinoma, emphasizing the need for increased awareness of thyroid malignancies in patients with autoimmune polyglandular syndromes as underlying autoimmune conditions may influence cancer progression and therapeutic strategies.

Parathyroid carcinoma on secondary hyperpara-thyroidism: a case report

Rachida Bouattay[1], May Ferjani[1], Sabrina Farhani[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]ENT and Head and Neck Department, University Hospital of Fattouma Bourguiba, Monastir, Tunisia

Introduction

Parathyroid carcinoma is a rare endocrine malignant tumor accounting for less than 1% of all cases of primary hyperpara¬thyroidism. Preoperative diagnosis and management stills a real challenge. Here we report an unusual case of parathyroid carcinoma developing on secondary hyperparathyroidism and we identify diagnostic and management challenges of parathyroid carci-noma.

Observation

A 53-year-old man, with a chronic renal insufficiency on hemodialysis, operated 10 years ago of subtotal parathyroidectomy for secondary hy¬perparathyroidism with favorable outcome, was hospital¬ized for bone pain with hypocalcaemia and elevated serum Para Thyroid Hormone (PTH). Explorations showed hyper¬plasia of lower right parathyroid gland. Surgical exploration revealed polylobulated mass of 4 cm adherent firmly to the oesophagus and to recurrent nerve. Lower right para¬thyroidectomy was so performed. Histological examination concluded to parathyroid carcinoma. Patient normalized calcium and PTH levels. No recurrence was observed after 48 months of follow up.

Conclusion

Para¬thyroid carcinoma described in patients with secondary and ter¬tiary hyperparathyroidism caused by chronic renal failure, such as the case of our patient are rare. Parathyroid carcinoma is a rare malignant tumor which still presents challenges in diagnosis and treatment. Surgery with en-block resection of the tumor and involved surrounding structures is the principal modality of treatment. The prognosis is variable due to frequent recurrences.

Primary hyperparathyroidism and papillary carcinoma of the thyroid: about a case

Nawres Bouaziz[1], Nour Bziouech[1], Rachida Bouatay[1], Sabrine Farhani[1], Mehdi Ferjaoui[1], Amal El Korbi[1], Nawrez Kolsi[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]Fattouma Bourguiba University Hospital, ENT Department, Monastir, Tunisia

Introduction

Primary hyperparathyroidism (PHPT) is a frequently encountered endocrine disorder characterized by dysregulated parathyroid hormone (PTH) secretion, most commonly due to a parathyroid adenoma. The coexistence of PHPT and papillary thyroid carcinoma (PTC) is rare, with an estimated prevalence of 2.3–4.3%. This report presents a case of incidentally discovered PTC during the evaluation of PHPT.

Case Presentation

A 47-year-old female was admitted for the management of PHPT, initially detected during the investigation of persistent lumbosciatalgia. Laboratory findings revealed hypercalcemia (2.89 mmol/l) and significantly elevated PTH levels (1087 pg/mL). Morphological assessment included cervical ultrasound, which identified a 45 mm hypoechoic nodule in the retro-inferior thyroid region, highly suggestive of a parathyroid adenoma, along with bilateral thyroid nodules classified as EU-TIRADS 3. Cervical computed tomography (CT) confirmed a retrothyroidal tissue mass on the left side, with enhancement kinetics consistent with a parathyroid adenoma. SPECT-CT further supported the diagnosis by demonstrating an MIBI-avid tissue mass in the lower left pole, indicative of parathyroid origin. The patient underwent a left inferior parathyroidectomy and left thyroid lobectomy. Intraoperative frozen section analysis

confirmed parathyroid tissue and unexpectedly revealed a papillary thyroid carcinoma, necessitating completion thyroidectomy. The final histopathological examination identified an encapsulated papillary thyroid carcinoma in the left lobe measuring 1.4 cm, with lymph node involvement (1N+/N), classifying the tumor as pT1aN1aMx. Consequently, the patient was referred to the nuclear medicine department for adjuvant radioactive iodine therapy.
Discussion/Conclusion
The concurrent occurrence of PHPT and PTC remains an uncommon finding, with its underlying pathophysiology not yet fully elucidated. Several hypotheses suggest a potential link, including shared embryological origins and common genetic mutations. This dual pathology poses significant diagnostic and therapeutic challenges, particularly when thyroid cancer remains unrecognized preoperatively. A meticulous preoperative evaluation, including intraoperative frozen section analysis, is crucial to prevent the need for reoperation and to optimize patient outcomes.

Primary thyroid lymphoma: About 2 cases
Amira Bouchenna[1], Faycal Bendjebour[1], Wafia Mokhtari[1], Brahim Ghennam[1], Meriem Medjaher[1] & Meriem Bensalah[1]
[1]Central Hospital of Army Algiers, Algiers, Algeria

Introduction
Primary thyroid lymphomas are rare (2-5% of thyroid cancers and less than 5% of extra-ganglionic lymphomas). The most frequent types are B-cell lymphoma and MALT lymphoma. Posing a diagnosis problem, including differential diagnosis with anaplastic cancer. We report two different cases of thyroid lymphoma.
Observation
Case 1: 44-year-old patient, with no particular history, who consulted for a rapidly increasing goiter, cervical ultrasound found a mass classified as Eutirads 4 of 83x47mm at the expense of the right lobe on thyroiditis; thoracic CT scan confirmed the tumor which was expansive, infiltrative and compressive, plunging into the mediastinum. In view of dyspnea, a tracheotomy was performed. A biopsy returned in favor of a diffuse large cell lymphoma BCD20+, BCL6- chemotherapy Rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone (RCHOP) was initiated. After 6 courses, the PET-SCAN found a Deauville score of 3 in complete metabolic response. Case 2: 62-year-old patient who presented 3 months previously with a pathological fracture of the right leg on an osteolytic mass, the anatomopathological study returned in favor of a large B-cell lymphoma. The extension assessment found a large goiter at the expense of the left lobe with a large left totolobar nodule Eutirads 5 with adenopathies of which the biopsy found a diffuse large B-cell lymphoma, i.e. a second location, chemotherapy (RCHOP) was initiated.
Discussion
The risk of developing thyroid lymphoma is multiplied by 67 in case of lymphocytic thyroiditis. Because of their rarity and their clinical polymorphism, thyroid lymphomas have revealed diagnostic difficulties. Therapeutic conduct is currently well codified. Their prognosis, depending on the histology and stage of the disease, was favorable with a 5-year survival rate of 70 to 80%.
Conclusion
Due to the different therapeutic management, thyroid lymphoma is a diagnosis that must be mentioned in front of any cervical mass with rapid evolution, especially if there is a history of thyroiditis

Hypercalcemia as a first manifestation of metastatic neuroendocrine tumour
Barbora Havlinova[1,2,3], Alzbeta Ondrejkova[1] & Vaclav Stejskal[4]
[1]University Hospital Hradec Králové, The 3rd Department of Internal Medicine – Metabolic Care and Gerontology, Hradec Králové, Czech Republic; [2]Charles University, Faculty of Medicine in Hradec Králové, Hradec Králové, Czech Republic; [3]University Hospital Hradec Králové, The 3rd Department of Internal Medicine – Metabolic Care and Gerontology, Hradec Králové, Czech Republic; [4]University Hospital Hradec Králové, The Fingerland department of Pathology, Hradec Králové, Czech Republic

Neuroendocrine tumours are a rare, heterogeneous group of tumours arising from neuroendocrine cells, whose common feature is the production, accumulation and release of a biologically active hormone-like substance. They are dispersed in various tissues with the highest incidence in the gastrointestinal system. Most of the tumours grow slowly. They have a varied clinical symptomatology dependent on hormonal activity. Their occurrence is familial and sporadic. We present a case report of an 84-year-old biologically younger man with asymptomatic mild hypercalcaemia (3 mmol/l), which was a secondary finding on examination after a bicycle accident. CT scan of the abdomen revealed a bulky inhomogeneous lesion with a diameter of 8 cm with central disintegration in the right lobe of the liver, which was suspicious for metastasis. The patient's current personal history includes chronic heart failure with preserved left ventricular ejection fraction in atrial fibrillation, moderate aortic stenosis, arterial hypertension, and multinodular goitre with laboratory signs of hyperthyroidism. Endoscopic sonography and FNAB confirmed a neuroendocrine tumour grade 1–2. The tumour cells were immunopositive for creatine kinase, chromogranin, synaptophysin and insulinoma-associated protein 1. In particular, the proliferative activity assessed by Ki67 in hot-spots was around 5%. As a part of staging, whole-body scintigraphy was added. SPECT/low dose CT scintigraphy with ^{99m}Tc-Tektrotyd showed tumorous lesion with high somatostatin receptor expression in the caudate region of the pancreas and a disseminated lesion with marginally slightly increased somatostatin receptor expression in the right lobe of the liver. Paraneoplastic hypercalcemia (low PTH levels) was corrected with bisphosphonates. Considering the patient's age, comorbidities and asymptomatic course of the disease, the multidisciplinary team indicated palliative hormone therapy with Somatuline.

Endocrine status on glucose, thyroid and calcium metabolism after treatment for breast cancer in postmenopausal women
Kristian Buch-Larsen[1], Simone Diedrichsen Marstrand[1], Djordje Marina[1], Valdemar Mendez[1], Michael Andersson[2], Caroline Kistorp[1] & Peter Schwarz[1]
[1]Rigshospitalet, Department of Nephrology and Endocrinolgy, Copenhagen, Denmark; [2]Rigshospitalet, Department of Oncology, Copenhagen, Denmark

Introduction
Endocrine side effects to breast cancer treatment become more prevalent as survival rates increase making it relevant to know if, when and how to treat. Previously studies described a negative effect of chemotherapy on metabolism such as weight gain and an increased incidence of the diagnosis of type 2 diabetes.
Materials and Methods
We aimed to exploratively describe selected endocrine areas in postmenopausal women with non-metastatic breast cancer focusing on glucose, thyroid and calcium metabolism. Relevant blood samples were collected at baseline immediately before chemotherapy and after completing chemotherapy. Patients were compared to healthy controls at baseline.
Results
95 patients of which 64 were fasting had higher BMI before chemotherapy, higher fasting plasma glucose, fasting C-peptide and higher HOMA-IR compared to controls. Fasting plasma glucose and fasting C-peptide were still significantly higher in patients when adjusted for BMI. After chemotherapy patients had lower ionized calcium and free T4 and higher levels of parathyroid hormone and 25-OH-Vitamin-D. No significant change was seen in blood test relevant for the glucose metabolism.
Conclusions
At baseline patients already show signs of impaired glucose metabolism compared to controls. Chemotherapy doesn't appear to change parameters of glucose metabolism. After chemotherapy changes are seen in thyroid and calcium metabolism though changes are interpreted as having no clinical significance.

JOINT3901
Treatment of a catecholamine-secreting vagal paraganglioma with fractionated stereotactic radiotherapy
Sandra Keller[1], Andrea Wiedmann[1] & Stefan Bilz[1]
[1]Kantonsspital St. Gallen, Endocrinology and Diabetology, St. Gallen, Switzerland

Background
Glomus vagale tumors are rare neuroendocrine tumors belonging to the group of head and neck paragangliomas (HNPGLs). The most common symptom is a neck

mass, followed by cranial nerve palsies. In very rare instances, vagal paragangliomas (VPGLs) secrete catecholamines. The management of HNPGLs has changed dramatically in recent decades. Surgery was historically the first-line treatment for all HNPGLs and remains the primary approach for functional HNPGLs. While potentially curative, surgery carries a high risk of morbidity, including cranial nerve deficits and vascular injury. In VPGLs, a postoperative vagal deficit is almost inevitable. Fractionated stereotactic radiotherapy (FSRT) has emerged as a viable treatment option for non-secreting HNPGLs, offering excellent long-term tumor control with a low complication rate. However, data on FSRT for functional HNPGLs/VPGLs remain limited.
Case Presentation
A 65-year-old patient presented to the emergency department with syncope. A CT scan revealed a neck mass suspicious for a paraganglioma, prompting further evaluation. There was no evidence of cranial nerve palsy. His past medical history was notable for a 10-year history of hypertension, well controlled with Candesartan and Amlodipine. There were no additional signs or symptoms of catecholamine excess. Biochemical testing revealed significantly elevated plasma-free normetanephrine (6.38 nmol [0.04–1.39 nmol/l]) and methoxytyramine (0.22 nmol/l [$<$ 0.06 nmol/l]). MRI demonstrated a VPGL in loco typico, measuring 41 $\times$ 20 $\times$ 43 mm. Whole-body MRI and DOTATATE-PET/CT showed no evidence of multicentric disease, metastases, or synchronous pheochromocytoma/sympathetic PGL. Genetic testing did not detect pathogenic variants in PGL susceptibility genes. Surgical and radiotherapeutic options were discussed. The patient opted for FSRT. A total dose of 25 Gy in five fractions was administered. Prior to radiotherapy, the patient was started on phenoxybenzamine. During a 11-month follow-up, the patient developed no new symptoms of catecholamine excess. His blood pressure remained well-controlled. On MRI, the VPGL remained stable in size. Plasma metanephrine levels dropped significantly six months post-treatment (normetanephrine: 3.84 nmol/l, methoxytyramine: 0.13 nmol/l) and remained stable at 11 months (normetanephrine: 4.26 nmol/l, methoxytyramine: 0.20 nmol/l), but normalization has not yet been achieved.
Conclusion
Our case demonstrates that FSRT can reduce catecholamine secretion from functional VPGL within a short follow-up period. However, a longer follow-up is necessary to assess the further trajectory of metanephrine levels and to better evaluate the appropriateness of FSRT for managing functional VPGLs. The long-term efficacy and durability of response of FSRT may only become fully apparent over several years.

Unexpected evolution of an ACTH secreting pitnet

Samir Mkaouer[1], Elyes Kamoun[1], Meriem Yazidi[1], Awatef Mekaouer[1], Nadia Khessairi[1], Ibtissem Oueslati[1], Fatma Chaker[1], Sonia Nagi[2] & melika Chihaoui[1]
[1]CHU La Rabta, Endocrinology Department, Tunis, Tunisia; [2]Neurology Institute of Tunisia, Radiology Department, Tunis, Tunisia

Introduction
Pituitary carcinoma (PC) is a rare tumor and represents only 0,1 - 0,2% of all pituitary tumors. Early diagnosis of PC is often challenging and requires the presence of metastases.
Observation
A 59-Year-old diabetic patient was referred to our clinic. A Cushing syndrom was suspected due to hypercatabolic signs and was confirmed by elevated urinary free cortisol (UFC) = 800µg/24h [22-110]. Due to elevated ACTH levels (95pg/ml [10-50]), a pituitary MRI was performed and showed a 7mm pituitary adenoma. The patient underwent a complete transsphenoidal resection. Pathology examination showed a Corticotrop benign pitnet with a Ki67 = 1%. After surgery, diabetes and hypertension have improved, and the patient had a corticotropin deficiency. Three months after surgery, due to worsening of blood pressure and diabetes, dexamethasone suppression test was performed with cortisol levels at 1,9 µg/dL, suggesting the relapse of the Cushing disease with a normal pituitary MRI. The patient went through Radiotherapy (54 Gy) and was put on Ketoconazole 400mg per day for two years with normal UFC levels. After withdrowal of ketoconazole and increase of UFC levels, the patient underwent bilateral adrenalectomy and was under hydrocortisone and fludrocortisone replacement. After six months, she developped hyperpigmentation with ACTH levels of 1890pg/ml suggesting Nelson's syndrom, later associated with ptosis and mydriasis. A pituitrary MRI showed a 25*21*13mm macroadenoma with cavernous and optic chiasma extension. She went a second Transsphenoidal Surgery followed by gamma night radiotherapy. Pathological examination showed an atypic pitnet with Ki67 = 10% $>$ 3%, complicated by dural metastases after two years. She was treated by temozolomide for 15 months.
Conclusion
Although ACTH pitnet is a disease with frequent relapse, the Transformation of a benign pitnet to a PC is rare. A review showed that the mean time interval from initial diagnosis to diagnosis of PC was 10.7 years. This suggests to be careful and repeat MRIs if there are signs of aggressivity.

Calcium as a tumour marker in PTHrP-secreting pancreatic neuroendocrine tumour: a case of multimodal management

Alexandra Zueva[1], Jonathan Wadsley[2], Shamiso Masuka[3] & Alia Munir[3]
[1]University of Sheffield, Sheffield, United Kingdom; [2]Weston Park Cancer Centre, Sheffield, United Kingdom; [3]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Introduction
Pancreatic neuroendocrine tumours (PNETs) have an annual incidence of less than 1 case per 100,000 people, with the majority being nonfunctional. PTHrP-secreting PNETs are particularly rare, with few cases reported globally. Hypercalcemia caused by PTHrPoma can be life-threatening and requires a multimodal and multidisciplinary approach for effective management. In such cases, calcium levels may serve as a reliable tumour marker, particularly when PTHrP assays are unavailable.
Case presentation
A55-year-old woman was diagnosed with an 8 cm pancreatic tumour, secreting PTHrP (2.2 pmol/l, normal range 0-1.8), with multiple liver and spleen metastases. The patient presented with cough and hypercalcemia (2.85 mmol/l) with a fully suppressed PTH. Imaging revealed a large pancreatic mass, and histology confirmed a neuroendocrine tumour (ENETS Grade 2, Ki67 7%). Initial treatment with somatostatin analogue (SSA) Sandostatin® LAR® led to excellent response and subsequent normocalcaemia. However, a side effect of extreme insomnia prompted a switch to Somatuline® Autogel®. Progression then led to treatment combination with Peptide Receptor Radionuclide Therapy (PRRT) with Lutathera®. After 4 cycles of PRRT, tumour shrinkage was observed and normalisation of calcium and PTH levels was achieved, although PTHrP assay was no longer available. The patient continued to experience insomnia with SSA, including during a trial of subcutaneous short-acting octreotide. Given her favourable response to PRRT, SSA therapy was eventually discontinued to improve her quality of life. Subsequent hypercalcaemia was poorly controlled with zoledronate and denosumab, leading to the rapid development of bilateral hip osteoarthrosis, requiring joint replacements. As the disease and hypercalcaemia progressed despite a re-trial of Somatuline® Autogel®, chemotherapy was initiated. The patient received 2 cycles of Capecitabine/Temozolomide by 8 years after her original presentation, resulting in a reduction of the primary tumour and liver metastases, along with normocalcaemia. Severe depression ensued, which was managed with citalopram and required a treatment break.
Conclusion
PTHrP-secreting PNETs are extremely rare and are associated with hypercalcaemia and increased mortality. Successful management often requires a combination of therapies, including SSAs, PRRT and chemotherapy, conferring tumour and calcium levels control and ultimately prolonging survival. This case highlights the importance of personalised management strategies for NETs, with calcium serving as a reliable tumour marker for disease monitoring and treatment assessment.

Hypoglycemia secondary to metastatic solitary fibrous tumor: doege-potter syndrome. importance of the IGF-II/IGF-I ratio

Miguel-Angel Ruiz-Gines[1], Juan-Antonio Ruiz-Gines[2], Macarena Dubert-Perez[1], Mercedes Agudo-Macazaga[1], Laura Cervera-Palou[1], Miguel Lopez Abechuco-Ruiz[1], Maria Zurdo-Lopez[1], Miguel Juan-Asperilla[1], Laura Morell-Jurado[1], Maria Ruiz-Ancos[3], Belen-Maria Martinez-Mulero[3], Elvira Villarrubia-Martin[1], Vanessa Portillo-Maestre[1] & Susana Vicente-Pantoja[1]
[1]Hospital Universitario de Toledo, Laboratory Medicine, Toledo, Spain; [2]Hospital Clínico Universitario Lozano-Blesa, Neurosurgery, Toledo, Spain; [3]Hospital Universitario de Toledo, Endocrinology, Toledo, Spain

Introduction
Doege-Potter syndrome is a rare clinical entity characterized by recurrent hypoglycemic events caused by non-pancreatic tumors secreting an incompletely

processed high-molecular-weight form of Insulin-like Growth factor-II (IGF-II). Usually caused by a solitary fibrous tumor (SFT) and mediated by the binding of IGF-II precursors to insulin receptors. They have a benign behavior in most cases and rarely produce metastasis, although up to 12% present malignant behavior. They are more frequent in men, between the sixth and eighth decade of life and predominate in the right hemithorax. The treatment of choice is surgery, but in unresectable cases, although glucocorticoids (GC) play a major role, the approach is controversial. Our aim is to present a case of Doege-Potter syndrome and the importance of the IGF-II/IGF-I ratio in individuals with hypoglycemia secondary to IGF-II-producing STF.

Case report

A 65-year-old male diagnosed with pleural SFT. He was admitted to the Emergency Department due to massive pleural effusion secondary to a large mass in the left hemithorax (> 20 cm) and extrapulmonary extension. Clinical signs of IGF-II-mediated hypoglycemia (<20 mg/dL): C-peptide 0.19 ng/mL, insulin <0.2 uU/mL, IGF-I 53.3 ng/mL (93-224), IGF-II 941 ng/mL (350-1000), IGF-II/IGF-I 17.6 (VN <10). Treatment with GC was started, requiring escalation to 1.5 mg/kg/day and glucagon to prevent hypoglycemia, so diazoxide was added to reduce the GC dose. Continuous interstitial glucose monitoring (CGM) and selective radiotherapy (SR) were started which facilitated management and subsequent surgical resection.

Discussion and conclusions

Hypoglycemia secondary to large IGF-II-producing STF is a therapeutic challenge. CGM is an aid in management, as well as a response to diazoxide and SR described in the literature to achieve tumor control and hypoglycemia that allows curative surgical treatment. However, a recurrence rate of up to 15% is estimated according to described series. These are slow-growing tumors with few initial respiratory symptoms and in which hypoglycemia may be the initial symptom, so emphasis should be placed on the evaluation of thoracic imaging studies in the event of persistent hypoglycemia. The plasma IGF-II/IGF-I ratio better indicates the Doege-Potter syndrome's metabolic impairment than isolated measurements of circulating IGF-II or IGF-I levels.

An unusual evolution of a malignant metastatic pheochromocytoma: A case report

Ghada Sabbagh[1], Hajer Kandara[1], Marwa Chiboub[1], Manel Jemel[1] & Ines Kammoun[1]

[1]National Institute of Nutrition, Endocrinology, Tunis, Tunisia

Introduction

Malignant metastatic pheochromocytoma is a rare neuroendocrine tumor that originates from chromaffin cells in the adrenal medulla, distant metastases confirm its malignancy. We present a case of a malignant metastatic pheochromocytoma, emphasizing its uncommon evolution.

Case presentation

A 45 year old patient with history of congenital ictyosis presented with decreased visual acuity and headaches dating to one month. Ophthalmic examination showed stage 3 papillary edema, a cerebral MRI showed an expansive intrasellar process bulging into the sphenoid sinus encompassing the cavernous carotid artery. A TAP CT showed left latero-aortic retroperitoneal tissue mass measuring 12.5*12 cm at the expense of the adrenal gland. The diagnosis of pheochromocytoma was mentioned in the face of blood pressure peaks with hypertensive emergency and the Menard triad and confirmed with Urinary methoxyl derivatives > 20 times the upper limit of normal and Plasma methoxyl derivatives > 10 times the upper limit of normal. MIBG scintigraphy showed: left adrenal pheochromocytoma with bone metastases and at the level of the sella turcica. Our patient was operated two years after diagnosis, Left adrenalectomy with left nephrectomy were performed while bone metastases were left untreated, the operative consequences were simple. The anatomopathological examination showed Morphological appearance and immunological profile compatible with pheochromocytoma. The postoperative evolution was marked by the normalization of blood pressure figures objectified by a blood pressure Holter, no menard triad and normalization of plasma metanephrine (Normetanephrine = 1.57 (< 1.07nmol/l), Metanephrine <0.1nmol/l (<0.33)). Seven years after diagnosis our patient presents with a conserved general state.

Conclusion

Five year survival rates after surgery for malignant pheochromocytoma vary between 34 and 60% with high risk of recurrence. The particularity of our patient is conserved general state, normalization of metanephrines and stable metastases up to 5 years after surgery. This case highlights the diagnostic and therapeutic complexity and severe systemic implications of malignant pheochromocytoma. While surgical resection of metastases is an option in oligometastatic cases, it was not feasible for this patient. Novel therapeutic strategies, including internal radiotherapy (I131-MIBG), hepatic chemoembolization, systemic chemotherapy, and targeted therapies such as anti-angiogenics (Sunitinib), offer promising alternatives for managing metastatic disease.

Thyroid metastasis of pulmonary choriocarcinoma: a rare and challenging diagnosis

Jaweher Kechiche[1], Abir Meherzi[1], Taieb Ach[2], Habiba Ben Sghaier[1], Mouna Bellakhdher[1], Jihen Houas[1], Malika El Omri[1], Ghada Saad[2], Monia Ghammem[1], Yosra Hasni El Abed[2], Wassin Kermani[1] & Mohamed Abdelkefi[1]

[1]Farhat Hached University Hospital, ENT Head and Neck Surgery, Sousse, Tunisia; [2]Farhat Hached University Hospital, Endocrinology Departement, Sousse, Tunisia

Introduction

Metastatic disease to the thyroid is an uncommon but welldocumented event and accounts for 1–9 % of all thyroid malignancies. The three most common neoplasms to metastasize to the thyroid were from the kidney, lung, gastrointestinal tract and breast, respectively. The treatment options in patients with metastatic disease to the thyroid gland should be made based upon the condition of the patient, extent of the disease, stage, and volume The aim of this report is to present this case and discuss the diagnostic difficulties of an unusual presentations of thyroid metastasis of choriocarcinoma

Materiel and methods

We report a rare case of thyroid metastasis from lung choriocarcinoma.

Observation

A 55 year-old male patient, with a history of Hodgkin's lymphoma treated with radiochemotherapy in 1998, complained of a cervical mass for 4 month. He was referred for exploration and management of the mass. On examination, a 10-cm growth was palpable on the right paramedian anterior neck, in favour of a heterogenous thyroid goiter. β -hCG was elevated. CT scan showed a suspicious excavated mass in the posteroinferior segment of the left inferior lobe of the lung, along with solid nodules and confluent mediastinal and hilar enlarged nodes. Cervical lymphadenopathies, adrenal and cerebral nodules indicative of metastasis, were also observed, and heterogeneous thyroid goiter. A primary pulmonary malignancy was suspected. Fine needle aspiration showed anaplastic malignant cellsA thyroid biopsy was performed, indicating the presence of trophoblastic cells characteristic of a choriocarcinoma metastasis in the thyroid gland. These findings were corroborated by the presence of the same malignant cells in the bronchial biopsy. β -hCG was elevated. The multidisciplinary team decision was to start chemotherapy. Unfortunately, the patient passed away before he could be started on chemotherapy.

Conclusions

Metastasis to the thyroid gland is a rare condition that may pose a diagnostic challenge. the overall prognosis is poor.

A rare combination of three endocrine neoplasms and cervical adenocarcinoma

Nino Turashvili[1,2]

[1]SSU and Ingorokva's University Clinic of High Medical Technologies'', Tbilisi, Georgia; [2]New Vision University'', Tbilisi, Georgia

Introduction

Papillary thyroid carcinoma, prolactinoma and nonfunctioning adrenal adenoma are relatively common endocrine tumors. However, their occurrence alongside cervical adenocarcinoma in a single patient is extremely rare. When such a combination is present, it is crucial to evaluate the nature of the multiple tumors—whether they are primary, metastatic or syndromic.

Case Report

A 45-year-old woman visited the clinic in 2023 with galactorrhea. Several years prior, she had been diagnosed with hyperprolactinemia at a local hospital and had been periodically treated with cabergoline. Her past medical history also revealed a nontoxic multinodular goiter. In 2022, she underwent a hysterectomy with bilateral salpingo-oophorectomy due to cervical adenocarcinoma, followed by

radiation therapy. Subsequent studies, including a computed tomography (CT) scan (recommended by an oncologist), revealed a right adrenal incidentaloma—a 25 mm homogeneous, lipid-rich adrenal mass with unenhanced HU of -10. Adrenal hormonal tests were normal. Additional laboratory tests revealed normal levels of TSH, FT4, creatinine, ALT, AST, calcium, PTH, HbA1c, glucose and C-peptide. Serum prolactin was again elevated. The breast examination showed no abnormalities. A cranial MRI revealed a rounded 7×8×8 mm pituitary mass, with no compression of the optic chiasm. Additional pituitary hormonal tests were normal. All other causes of hyperprolactinemia were ruled out and cabergoline was restarted. A repeated ultrasound examination of the thyroid gland revealed multiple small, non-oval, markedly hypoechoic nodules with microcalcifications in the left lobe and isthmus. Cytological examination of the dominant nodule (9×6×8 mm) revealed papillary carcinoma. Thyroidectomy with lymphadenectomy was performed. Histological examination confirmed multifocal papillary microcarcinomas with microscopic invasion into the perithyroidal soft tissue. A multidisciplinary team recommended radioiodine therapy. Follow-up studies after 1 year showed an excellent response. After 1 year, the pituitary microadenoma remained unchanged. The patient feels better and continues taking levothyroxine and cabergoline.

Discussion

When two or more endocrine tumors are detected, it is essential to exclude multiple endocrine neoplasia (MEN) syndrome. According to current data, our patient does not have primary hyperparathyroidism (the most common and early manifestation in MEN-1 and MEN-4) or any enteropancreatic tumors. The family history is unremarkable. The patient was informed about genetic testing, which was not performed yet.

Conclusion

The combination of three primary endocrine tumors with concomitant non-endocrine cancer in a single patient is a rare occurrence that requires a multidisciplinary approach and regular follow-up.

Successful management of papillary thyroid microcarcinoma with distant metastases: a case report

Aiste Stonyte[1], Emilija Tumenaite[1] & Raimonda Klimaite[1,2,3]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Endocrinology, Kaunas, Lithuania

Introduction

Papillary thyroid carcinoma (PTC), a subtype of differentiated thyroid carcinoma (DTC), is classified as papillary thyroid microcarcinoma (PTMC) when ≤1.0 cm. Distant metastases from PTMC are rare (0-2.8 %). Therefore, long-term assessment of patients receiving surgical treatment and radioactive iodine is essential, since approximately 50% of DTC patients with distant metastases are classified as radioiodine-refractory, influencing survival rates.

Case

A 51-year-old female presented with a two-year history of a right neck mass.

Neck ultrasound

Revealed a 0.9×0.6 cm lymph node with hyperechoic foci in the right level IV region.

Thyroid ultrasound

Identified a ~0.2 cm hypoechoic nodule with ill-defined margins near the capsule on the right lobe (EU-TIRADS 5).

Fine-needle aspiration biopsy

Confirmed metastasis of PTC.

Laboratory tests

TSH, FT4, FT3, anti-TPO, anti-Tg within reference ranges.

Surgery

Subsequently, in April 2024 the patient underwent thyroidectomy and lymphadenectomy. TSH suppression (<0.1 mIU/l) is maintained with L-thyroxine 175 mg/day.

Microscopic examination

A 0.3 cm poorly defined, non-encapsulated tumor with papillae and pleomorphic cells, not invading the capsule; the pathological neck lymph node was not identified or removed.

SPECT/CT

Whole-body SPECT/CT revealed lung foci and I-131 uptake in the thyroid lodge and a level VI lymph node. The patient was diagnosed with stage II PTC, pT1aN1M1, and bilateral lung metastasis.

Radioiodine therapy

A cumulative dose of 6,1 GBq of iodine-I31 treatment was administered. SPECT/CT showed resolved lung I-131 uptake and faint residual thyroid and lymph node uptake. On November 2024, laboratory results: TSH at 0.01 mIU/l (n.r. 0.4-3.6), thyroglobulin at 0.2 mg/l, and anti-TG at 6.1 kU/l (n.r. <13.6). On January, 2025, thyroglobulin was <0.2 mg/l, and anti-TG was <1.3 kU/l. Concurrently, whole-body scintigraphy was performed. Laboratory and scintigraphy results proved an excellent biochemical and radiological response.

Discussion

A 0.3 cm PTMC, histologically benign in nature, caused metastases in the cervical lymph nodes and lungs. Nevertheless, I-131 therapy was effective in treating patient's condition. Although active surveillance is becoming the standard approach for PTMC, the potential for metastasis in some cases highlights the need for prompt surgical intervention.

Medullary thyroid cancer and infiltrating ductal carcinoma of the breast: a rare association

Ghita Khamel[1], Meriem Benrkia[1], Zineb Habbadi[1], Kaoutar Rifai[1], Hind Iraqi[1] & Mohamed Hassan Gharbi[1]
[1]CHU Ibn Sina, Rabat, Morocco

Introduction

Thyroid and breast cancers are among the most common cancers, but their coexistence, in particular the association of medullary thyroid carcinoma (MTC) and breast cancer, remains relatively unexplored. This case report illustrates a medullary thyroid carcinoma revealed during the post-therapeutic follow-up of an operated ductal carcinoma of the breast.

Observation

This is a 57-year-old female patient with a history of breast cancer in her sister. She was operated on 10 years ago for ductal carcinoma of the left breast treated by total mastectomy, adjuvant chemotherapy and radiotherapy. The patient was declared in remission, and annual surveillance was initiated. The evolution was marked by the observation of a cervical mass 2 years ago during a post-treatment follow-up consultation. Cervical ultrasound revealed a 22 mm right totolar nodule classified as eutirads 3. A cytopunction was performed and found to be cytologically suspicious of malignancy. The patient underwent total thyroidectomy, the anatomopathology was in favour of a 2.8 cm medullary carcinoma with, on immunohistochemical study, a low-grade MTC with positive calcitonin and negative thyroglobulin. A calcitonin and CEA assay at 6 MONTHS post-op were negative. There were no other components of NME 2

Discussion

The links between CMT and breast cancer are not yet fully understood, but several hypotheses are being explored Although RET mutations have been widely studied in the context of thyroid cancers, several recent studies have suggested that this gene may also play a role in the development of certain types of cancer, including breast cancer. However, the involvement of the RET gene in breast cancer is still in the exploratory phase. It has been suggested that abnormal activation of the RET signaling pathway may contribute to the initiation or progression of certain breast cancers, although this link is less direct than for endocrine cancers. The mechanisms by which RET might contribute to breast cancer probably involve complex interactions with hormone receptors (such as estrogen receptors)

Conclusion

The association between medullary thyroid carcinoma and breast cancer is rare, but deserves special attention in cases where common risk factors, such as genetic mutations, are present

Papillary thyroid carcinoma associated with primary hyperparathyroidism: a rare occurrence

Afrah El Kaissi[1], Meriem Benrkia[1], Hajar Srifi[2], Jade Issouani[2] & Ahmed Anas Guerboub[2]
[1]CHU Ibn Sina - Rabat, Endocrinology, Rabat, Morocco; [2]Hôpital Militaire d'Instruction Mohamed V - Rabat, Endocrinology, Rabat, Morocco

Introduction

Primary hyperparathyroidism (PHPT) is a common endocrine disorder characterized by excessive parathyroid hormone secretion. While it is often associated with medullary thyroid carcinoma (MTC) in the context of multiple

endocrine neoplasia type 2 (MEN2), its association with papillary thyroid carcinoma (PTC) remains rare (1,2). Here, we report an exceptional case of this coexistence.
Case Report
A 67-year-old woman with type 2 diabetes complicated by chronic kidney disease was referred to endocrinology for hypercalcemia. Biological investigations confirmed PHPT. Cervical ultrasound showed multiple thyroid nodules, with the most concerning located in the right mediolobar region, measuring 5.4 × 4.6 × 4 mm and classified as EU-TIRADS V. It also revealed a hypoechoic lesion beneath the thyroid, suggestive of a parathyroid adenoma with a maximum diameter of 13 mm. This finding was confirmed by parathyroid scintigraphy, which identified a subisthmic parathyroid adenoma. Calcitonin levels were negative. A total thyroidectomy and parathyroidectomy were performed. Histopathological examination revealed an invasive micropapillary thyroid carcinoma (0.5 cm) in the right lobe, associated with a parathyroid adenoma. Postoperative assessment showed normalization of serum calcium and PTH levels, with complete remission achieved after a course of radioiodine (I-131) therapy.
Discussion & Conclusion
The co-occurrence of PTC and PHPT has been reported in 2.3–4.3% of patients undergoing surgery for PHPT (3). The underlying pathological mechanism linking these two conditions remains poorly understood and has not yet been fully elucidated. Current hypotheses point to the involvement of embryological factors and shared genetic pathways (1). Although this association is considered rare, recognizing it in clinical practice is essential to ensure an optimal management strategy for both conditions and improve patient outcomes (4).

A case of ectopic ACTH secretion caused by thymic neuroendocrine tumor (typical carcinoid) with metastasis to the breast after long-term remission

Aleksandra Zdrojowy-Welna[1], Marek Bolanowski[1], Aleksandra Jawiarczyk-Przybyłowska[1], Anna Brona[1], Joanna Syrycka[2], Konrad Pawełczyk[3] & Justyna Kuliczkowska-Płaksej[1]
[1]Wroclaw Medical University, Department and Clinic of Endocrinology and Internal Medicine, Wrocław, Poland; [2]Affidea PET/CT Diagnostic Center, Wrocław, Poland; [3]Lower Silesian Center of Oncology, Pulmonology and Hematology, Wrocław, Poland

Ectopic adrenocorticotropic hormone secretion (EAS) remains one of the most difficult challenges in endocrinology, representing between 9 and 18% of ACTH-dependent Cushing̲s syndrome (CS) cases. Thymic neuroendocrine tumors (NETTs) are rare, mostly aggressive tumors, that are responsible for about 5-16% of EAS in recent series. We present a unique case of 34-year old female with EAS caused by NETT - typical carcinoid. First disease manifestation occurred in April 2016, when patient presented with severe hypercortisolism, diagnosed as EAS. First-line cross-sectional imaging studies were inconclusive, only ^{68}Ga DOTA-TATE PET/CT revealed an oval lesion in the anterior mediastinum (1.9 x 1.3 cm) with subtle overexpression of somatostatin receptors (SUV max. 2.8). After initial treatment with steroid inhibitor (ketoconazole) the patient was sent to thoracoscopic removal of mediastinal tumor, in histopathological examination typical carcinoid without lymph node metastases was diagnosed. Postoperatively, transient adrenal insufficiency was observed with resolution of all symptoms. There was a diseases recurrence after 5 years of observation caused by a metastasis to the breast, shown in ^{68}Ga DOTA-TATE PET/CT and confirmed with breast biopsy. Again, treatment with steroid inhibitor (metyrapone) and tumor resection were curative. Last disease relapse appeared 7 years after initial treatment (January 2023), with severe hypercortisolism treated with osilodrostat. There was a local recurrence in the mediastinum and a thoracoscopic surgery was performed with good clinical and biochemical effect. The patients remains under a careful follow-up. In conclusion, our case proves that NETTs with EAS might present in young patients with well-differentiated tumor in histopathological examination and severe, life-threatening hypercortisolism despite small size of the primary lesion. ^{68}Ga-DOTATATE PET/CT is a very helpful tool to localize the tumor. There are only few descriptions of breast metastases from NETTs associated with EAS, our case was confirmed in biopsy and hormonally active. Finally, lifelong follow up should be performed despite complete remission after surgery.

Cervical lymph nodes metastasis revealing occult papillary thyroid carcinoma

Rachida Bouattay[1], Linda Misbah[1], May Ferjani[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]ENT and Head and Neck Department, University Hospital of Fattouma Bourguiba, Monastir, Tunisia

Introduction
Cervical lymph node metastasis revealing occult papillary thyroid carcinoma (PTC) is uncommon. This clinical situation raises double problem: problem of diagnosis, in the presence of a chronic lymphadenopathy without known primitive and on the other hand its impact on the prognosis of these micro carcinomas.
Patients and Methods
A Descriptive retrospective study including 6 cases of cervical node metastasis revealing PTMCs.
Results
The average age in our series was 60 years (40-84 years). The sex ratio was 0,5. All our patients presented with latero-cervical tumefaction. The topography was the sector II in 1 case, sector III in 3 cases and sector IV in two cases. The thyroid was not palpable in all patients. The fine needle biopsy performed in five cases, suggests the diagnosis of a lymph node metastasis of papillary carcinoma of the thyroid. Total thyroidectomy was performed with central and lateral neck dissection in all cases. All patients were referred for radioactive iodine (RAI) ablation therapy. The mean follow-up was 5 years.
Conclusion
A laterocervical mass may be the only presentation of a clinically occult thyroid microcarcinoma. The treatment is that of any thyroid carcinoma and provides a good oncological result despite the possibility of locoregional recurrence.

An unusual case of cervical mass.a case report

Jonay Rodríguez Morales[1], Maria Elena Jerez Arzola[1], Yolanda Zambrano Huerta[1], Ricardo Moya Medina[1], Pablo Delgado Moya[1], Virginia Collantes Alcalá[1], Carlos Lopez Sarmiento[1], Diego García Gonzalez[1], Bárbara Alonso Moreno[1], Ana Cerezales Calviño[1] & Covadonga Rodríguez Mangas[1]
[1]Hospital Universitario Doctor José Molina Orosa, Arrecife, Spain

Primary thyroid sarcoma is a rare tumor. It confers a poor prognosis due to its metastatic capacity. Differential diagnosis is a challenge due to its low prevalence. We present the case of a primary thyroid sarcoma in a 71-year-old female patient admitted for upper airway obstruction related to a voluminous mass dependent on the left thyroid lobe with thrombosis of the internal jugular vein. In addition, the CT scan shows two nodules in the right lung. She required admission to the intensive care unit requiring tracheostomy due to the unresectability of the tumor. The results of the incisional biopsy showed data compatible with primary high-grade thyroid sarcoma. During hospitalization she had two episodes of airway obstruction with admission to the ICU for poor secretion management. In addition she had an urinary tract infection by *Klebsiella pneumoniae ESBL* and febrile neutropenia after oncological treatment was started. She was discharged after speech therapy rehabilitation and after receiving adequate nutritional support. She is currently being treated with doxorubicin. According to epidemiology, only 142 cases of primary thyroid sarcoma have been described in the medical literature. Given its rarity, there are no imaging techniques to differentiate it from other common thyroid tumors. The differential diagnosis should be made with thyroid lymphoma and anaplastic thyroid cancer. Its treatment is based on the pillars of surgery, chemotherapy and radiotherapy,

although there is still no defined line. The clinical manifestations consisting of a rapid increase of a painless mass in the neck with obstruction of the airway should make us consider this extremely rare and aggressive entity.

Incidental detection of papillary thyroid carcinoma on 18F-FDG PET/CT: a case report

Fatma Chaltout[1], Imen Mhiri[1], Ghada Mani[1], Yesmine Elloumi[2], Issam Jardak[1], Salma Charfeddine[1], Mohamed Maaloul[1], Fatma Hamza[1] & Khalil Chtourou[1]
[1]Habib Bourguiba University Hospital, Nuclear Medicine Department, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Sfax, Tunisia

18F-FDG PET/CT is widely used in oncology for staging and monitoring various malignancies, but it can also reveal unexpected findings, including thyroid nodules. Incidental detection of papillary thyroid carcinoma (PTC) on PET imaging is uncommon and often requires further evaluation. We report the case of a 50-year-old woman undergoing treatment for follicular lymphoma. As part of the initial staging workup, an 18F-FDG PET/CT was performed, revealing a hypermetabolic nodule in the upper right thyroid lobe. A cervical ultrasound confirmed the presence of a suspicious thyroid nodule, and a fine-needle aspiration biopsy was performed. Cytological analysis was suggestive of papillary thyroid carcinoma (Bethesda V). Given these findings, the patient underwent total thyroidectomy with bilateral recurrent lymph node dissection. Histopathological analysis confirmed a 1.3 cm papillary thyroid carcinoma with focal capsular invasion and clear surgical margins. Lymph node dissection was positive on the left side. Consequently, the patient was scheduled for radioactive iodine therapy. This case highlights the role of 18F-FDG PET/CT in detecting incidental thyroid malignancies in patients with other primary cancers. It underscores the importance of further evaluation of hypermetabolic thyroid nodules to ensure timely diagnosis and appropriate management.

Unusual skeletal muscle metastasis from poorly differentiated thyroid carcinoma: a rare presentation

Fatma Chaltout[1], Ghada Mani[1], Imen Mhiri[1], Yesmine Elloumi[2], Issam Jardak[1], Salma Charfeddine[1], Mohamed Maaloul[1], Fatma Hamza[1] & Khalil Chtourou[1]
[1]Habib Bourguiba University Hospital, Nuclear Medicine Department, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Sfax, Tunisia

Poorly differentiated thyroid carcinoma (PDTC) is a rare and aggressive form of thyroid cancer, with metastases typically involving the lungs, bones, and lymph nodes. However, skeletal muscle involvement remains an exceptional occurrence. We report the case of a 51-year-old woman who initially underwent total thyroidectomy with bilateral mediastino-recurrential lymph node dissection for a poorly differentiated carcinoma arising from an invasive follicular thyroid carcinoma. Histopathological examination revealed the presence of vascular emboli and associated chronic lymphocytic thyroiditis. The patient received two courses of radioactive iodine therapy, resulting in complete clinical, biological, and isotopic remission. Four years later, the patient presented with two palpable subcutaneous nodules in the right sternocleidomastoid muscle, measuring 10 mm and 11 mm on ultrasound. A suspicious right submandibular lymphadenopathy was also noted. Serum thyroglobulin levels under TSH suppression showed a mild elevation from 0.1 to 0.46 ng/mL. 18F-FDG PET/CT revealed metabolically active involvement of the right sternocleidomastoid muscle, associated with bilateral subcentimetric cervical lymph nodes with low metabolic activity. Theses findings were suggestive of muscle metastasis from the known primary thyroid carcinoma. As a result, the patient was considered for surgical excision. This case highlights a rare presentation of PDTC with isolated skeletal muscle metastasis, underscoring the importance of considering atypical metastatic sites in recurrent thyroid cancer to guide appropriate therapeutic decisions.

Adrenocortical carcinoma: a deadly challenge

Nada Ait Kassi[1], Dounia Talbi[2], Habbadi Zineb[1], Fatima Toulali[1], Ghizlane Sabbar[1], Kaoutar Rifai[1], Hinde Iraqi[1] & Mohamed El Hassan Gharbi[1]
[1]Ibn Sina Hospital Mohamed V University, Endocrinology, Rabat, Morocco; [2]Ibn Sina Hospital Mohamed V University, Endocrinology, Rabat, Morocco

Background
Malignant adrenocortical carcinoma (ACC) is a rare, aggressive endocrine malignancy with a poor prognosis, even with therapeutic intervention. Tumor size and metastatic spread significantly influence the disease's clinical course. Despite advancements in diagnostic and treatment approaches, managing ACC remains challenging, necessitating a multidisciplinary strategy.
Case Presentation
We report the case of a patient presenting initially with nonspecific abdominal pain managed with symptomatic treatment. Persistent symptoms led to further imaging, revealing a large right adrenal mass measuring 105 × 107 × 71 mm, accompanied by pulmonary, lymph node, and retroperitoneal metastases. Clinical examination showed hypercorticism, hyperandrogenism, and signs of virilization. Laboratory investigations confirmed elevated urinary free cortisol (8 times normal), testosterone (0.53 ng/ml), and SDHEA (84.82 µg/dl), alongside hypokalemia (2.5 mmol/l), which required correction. Negative plasma methoxylated derivatives excluded pheochromocytoma. Pathological confirmation of malignant ACC was obtained via biopsy. Despite initiating a chemotherapy protocol, the patient succumbed shortly after admission to the oncology unit.
Discussion
ACC's clinical presentation often varies, ranging from asymptomatic incidentalomas to severe hormonal dysregulation and metastatic disease. In this case, the constellation of virilization and hypercortisolism highlights the functional nature of the tumor. Imaging and biochemical workup were pivotal in rapid diagnosis—unfortunately, the advanced stage at presentation limited therapeutic options. Current recommendations emphasize the importance of early detection through vigilant monitoring of incidental adrenal masses and hormonal assessment. Treatment modalities include surgery for localized disease, systemic therapies such as mitotane, and palliative measures for advanced cases. The poor prognosis in advanced ACC underscores the need for novel therapeutic approaches and inclusion in clinical trials.
Conclusion
This case highlights the aggressive nature of ACC and the importance of a comprehensive, multidisciplinary approach in management. The rapid progression from diagnosis to mortality underlines the critical need for earlier detection and innovative therapeutic strategies to improve patient outcomes. Future research should focus on early biomarkers, targeted therapies, and optimizing systemic treatments to better address this devastating malignancy.

The hidden complexity of adrenal tumors: six cases that challenge diagnosis and treatment

Jelena Malinovic Pancic[1,2], Tamara Dojčinović[1,2], Bojana Caric[1,2] & Aleksandra Marković[1,2]
[1]University Clinical Centre of Republic of Srpska, Endocrinology, Banja Luka, Bosnia and Herzegovina; [2]Medical Faculty of University Banja Luka, Banja Luka, Bosnia and Herzegovina

Background
The detection of adrenal tumors has become increasingly common due to advances in imaging technologies, particularly computed tomography (CT). Adrenal tumors, which occur in 4-10% of the general population, are often found incidentally and tend to be asymptomatic. However, certain tumors can present significant clinical challenges, especially those with malignant potential or associated endocrine dysfunction. These tumors vary widely in histopathological types, from benign adenomas to more aggressive conditions like adrenocortical carcinoma and metastatic lesions.
Case Presentation
This report discusses six cases of adrenal tumors in Caucasian patients, including five females and one male. The tumors included ganglioneuroma, traumatic adrenal hematoma with fibrosis, pheochromocytoma, and adrenocortical carcinoma. Clinical presentations varied, with some patients experiencing hormone overproduction symptoms, while others were asymptomatic and discovered incidentally during imaging for unrelated reasons. Surgical intervention was performed in all cases, and diagnoses were confirmed via histopathological examination postoperatively. These cases underscore the clinical diversity of adrenal tumors and the complexities involved in their diagnosis and management.

Conclusions
The rising incidence of adrenal tumor detection, particularly incidentalomas, highlights the importance of comprehensive evaluation to differentiate between benign and malignant tumors. Hormonal imbalances caused by adrenal tumors can lead to significant endocrine disorders, while malignant tumors present serious health risks. A multidisciplinary approach that includes imaging, clinical evaluation, and histological analysis is critical for effective management and improved patient outcomes. Early diagnosis and treatment are essential, especially considering the potential for malignancy and endocrine complications. These cases also emphasize the need for a tailored approach in treating diverse patient populations, including Caucasians.

Parathyroid carcinoma synchronous with multifocal papillary thyroid microcarcinoma presenting as recurrent retropharyngeal hematoma in 45 years old woman
Magdalena Matejkova Behanova[1], Petr Lastuvka[1], Josef Vcelak[2], Kamila Vesela[2], Renata Chmelova[1], Jiri Oskar Zmek[1] & Jan Plzak[1]
[1]Motol University Hospital, Clinic of Nuclear Medicine and Endocrinology, Prague, Czech Republic; [2]Institute of Endocrinology, Prague, Czech Republic

Introduction
Spontaneous retropharyngeal hematoma is a rare entity that can be caused, among others, by the rupture of enlarged parathyroid gland. Only about 40 cases of spontaneous parathyroid hemorrhage have been reported in the literature. Most of them were parathyroid adenomas, with only a few cases of carcinoma described. Parathyroid carcinoma is very rare disease with incidence 3-10 cases/10 million annually. Synchronous parathyroid carcinoma and thyroid carcinoma are extremely uncommon and the cause of its coexistence is unknown.
Case Report
45 years old woman was referred to emergency for sore throat and dysphagia. She had a history of similar event two years ago, which was diagnosed as retropharyngeal hematoma, managed conservatively without further investigation (serum calcium not tested). Actual CT from 4/2024 showed a neck mass 42x36x20mm compressing and deviating the right lobe of the thyroid gland. Laboratory: calcium 2,93 mmol/l (normal range 2,15 - 2,55), PTH 35,45 pmol/l (normal range 1,3 - 7,6), thyroid function normal. Neck ultrasound showed the same mass as CT and multinodular enlarged right thyroid lobe. Resection of the cervical mass and right hemithyroidectomy were provided in 6/2024. Histopathology: parathyroid carcinoma and two papillary thyroid carcinomas (PTC) 3 and 1 mm. The left hemithyroidectomy followed in 9/2024 with finding of another PTC 3 mm. Due to the presence of two cancers genetic testing was indicated. The patient was found to have a likely pathogenic germline frameshift variant in the tumour suppressor gene *POT 1* Lys384ValfsTer15 in a heterozygous state by whole-exome sequencing. It is known from the literature that loss of the tumour suppressor telomere shortening mechanism caused by autosomal dominant disruption of the *POT1* gene leads to clonal population expansion and genomic instability, which predisposes to a higher risk of cancer. Molecular genetic testing of the resected cancers will follow.
Conclusion
We present a case of recurrent retropharyngeal hematoma of the parathyroid origin. The diagnosis was established after the disease relapsed two years later. Laboratory analysis of serum calcium should be considered as a part of investigation in nontraumatic cervical hemorrhage. The germline mutation in the tumour suppressor gene *POT 1* in a heterozygous state predisposes to a higher risk of cancer and probably caused both parathyroid carcinoma and multifocal papillary thyroid carcinoma in this patient. Supported by Ministry of Health Czech Republic - DRO (Institute of Endocrinology - EÚ, 00023761).

JOINT1345
Effects of osilodrostat and metyrapone on 2D and 3D models of adrenocortical carcinoma cell lines viability: preliminary results
Mattia Biondo[1], Laura Tomasello[2], Giuseppe Pizzolanti[2,3], Giorgio Arnaldi[2] & Valentina Guarnotta[2]
[1]University of Palermo, Department of Biological, Chemical and Pharmaceutical Sciences and Technologies (STEBICEF), Palermo, Italy; [2]University of Palermo, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (PROMISE), Palermo, Italy; [3]ATeN Center, Palermo, Italy

Adrenocortical carcinoma (ACC) is a rare but aggressive malignancy, with a poor overall survival. It can present itself in different ways, but most of the patients display symptoms of hormonal excess. Mitotane is a treatment option as an adjuvant therapy after surgery or for unresectable/advanced ACC, also combined in a platinum-based therapy. It is an adrenolytic drug that affects adrenal steroidogenesis and interferes with mitochondrial function reducing cell viability. Other therapeutics are used to relieve the symptoms of ACC with hypercortisolism, such as metyrapone and osilodrostat, both steroidogenesis inhibitors. Specifically, osilodrostat is a drug that inhibits adrenal 11β-hydroxylase and blocks aldosterone synthase, which are enzymes acting in the final step of cortisol and aldosterone synthesis. The main objective of this research consists of the comparison of effects of mitotane, metyrapone and osilodrostat on adrenocortical carcinoma cell lines, such as SW-13 and NCI-H295R: the first is a non-secreting cell line, the second is a glucocorticoids-, mineralocorticoids-, and adrenal androgen-secreting line, often used as a model in experiments on human steroidogenesis. While the effects of metyrapone and osilodrostat on ACC hypercortisolism have been proven in the last few years, there is no specific data about their effects on tumoral cells viability and how they can influence them. In this view, a study involving both cell lines could be an effective method to assess valuable information from an *in vitro* model. Both for SW-13 and NCI-H295R cells, the experiments were performed with 2D cultures and then 3D models (e.g. spheroids) to reproduce the complex structure of an *in vivo* environment. The cultures were treated with different concentrations of mitotane, metyrapone and osilodrostat. Moreover, a combination of mitotane and osilodrostat and of mitotane and metyrapone were tested on ACC cell cultures. 2D models were cultured in DMEM-F12 medium supplemented with 10% of fetal bovine serum (SW13 cells) or with DMEM-F12 medium supplemented with 2.5% of Nu-Serum and ITS + Premix supplement (NCI-H295R). Cell viability was assessed with MTS assay. 3D models were obtained using specific microwell plates to be evaluated via a physical cytometer establishing information about spheroids features and indirectly to cell death extent. Although the study is currently in a preliminary phase, we evaluated changes in cell viability and in steroidogenesis in 2D models. The next step will consist of a deeper characterization and evaluation of 3D models.

Two unusual calcitonin negative medullary thyroid carcinomas
Cecilia Sanchez-Ragnarsson[1], Edelmiro Luis Menendez Torre[1] & Luis Fernandez[2]
[1]Hospital Universitario Central de Asturias (HUCA), Instituto de Investigación Sanitaria del Principado de Asturias, Endocrinology, Oviedo, Spain; [2]Hospital Universitario Central de Asturias (HUCA), Pathology, Oviedo, Spain

Medullary thyroid carcinoma (MTC) is a neuroendocrine tumor(NET) arising from parafolicular cells. It accounts for less than 5% of all thyroid tumors. The most characteristic feature of MTC is the production of calcitonin by tumor cells, turning it into a valuable tumor marker for diagnosis and follow up. Rare cases of calcitonin negative neuroendocrine tumors of the thyroid have been reported, and they represent a clinical challenge. We present 2 cases of unusual calcitonin negative MTC (CNMTC) First case is a 65 year old male, complaining with hoarseness and a neck mass, with suspicious lynph nodes in the neck and mediastinum, plus a vertebral T1 lesion on CT and PET scans sugestive of metastasis. FNA of the thyroid nodule was suspicious por MTC. Total thyroidcetomy plus neck and mediastinum disection was performed. T4aN1b M1 MTC was confirmed. Inmunohistochemistry (IHC) in the tumor was strongly possitive (+) for calcitonin, synaptophysin, CEA and TTF-1. No blood test for calcitonin was collected until three days after surgery, being undetectable at that point, and has remained so for the next 12 years of follow up, with also normal blood CEA levels, despite the bone lesion and a 2 cm suspicious mediastinum lymph node that persisted after surgery. Two years later, a pancreatic node newly appeared in scans and was finnally removed some after slowly growing on follow up with diagnosis of pancreatic NET G1PT2N0. Both the spine lesion and the neck were treated with radiotherapy after surgery and have remained stable, during follow up, without apperance of new lesions on multiple imaging tests performed. RET genetic testing in blood sample was inicially performed and negative and more recently NGS on tumor tissue showed no RET somatic mutations but a Gln61Arg mutation in HRAS gene. Case 2 is a 75 year old woman with an incidentally discovered thyroid nodule. Inicial FNA was suspicious for MTC, but her calcitonin serum levels were undetectable. A total thyroidectomy was performed and biopsy revealed a NET: IHC + for synaptophysin, TTF-1 and Cromogranin but negative for calcitonin, calcitonin related gen peptide and CEA. KI-67 index was 0,5%. Differential diagnosis was CNMTC or, less likely a thyroid metastases from another NET. A Galium PET scan showed no other lessions. Genetic testing in the tunor cells showed no mutations in RET nor in other genes tested (Oncomine panel).

Lymph node metastasis revealing a thyroid microcarcinoma in a patient monitored for laryngeal cancer

Doaa El Bazi[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]UHC Ibn Rochd, Department of Endocrinology, Metabolic Diseases and Nutrition, Casablanca, Morocco

Introduction
The cervical region is a frequent site of neoplastic pathologies, including primary cancer and secondary lesions. The incidental discovery of thyroid carcinoma during surgery for upper airway pathology is rare.
Observation
We report the case of a 69-year-old male patient, a chronic smoker weaned 30 years ago, who underwent total laryngectomy with cervical lymph node curage. Histopathological examination revealed a moderately differentiated keratinizing squamous cell carcinoma classified as pT4aN0Mx. The Lymph node dissection revealed a metastatic lymph node without capsular rupture from a papillary thyroid carcinoma in the right IIa territory. Two months later, the patient underwent total thyroidectomy, with histopathological examination of a 7mm infiltrating vesicular variant papillary microcarcinoma of the right lobe with vascular emboli classified as pT1aN1bMx, at high risk of recurrence. The patient was scheduled for radioiodine therapy.
Discussion and conclusion
The association of thyroid carcinoma with laryngeal cancer is rare. There is no standardized therapeutic protocol for the simultaneous treatment of laryngeal and thyroid cancer. Hence the importance of a thorough examination of the cervico-facial region during surgical treatment of cervical neoplasia.

Background
Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma, characterized by its aggressive nature and diverse clinical presentations. While DLBCL primarily affects lymphoid tissues, extranodal involvement can occur in various organs, including the pancreas. Pancreatic involvement in DLBCL is rare and poses unique diagnostic and therapeutic challenges.
Case report
We present the case of a 44-year-old female with no prior history of diabetes or endocrine disorders, who initially presented with an inguinal adenopathy. A biopsy of the inguinal lymph node revealed giant cell lymphoma, characterized by CD20+ positivity and a high Ki-67 proliferative index of 90%. Subsequent imaging, including a PET-FDG scan, revealed extensive involvement of the entire pancreas by the lymphoma. Notably, despite the widespread pancreatic infiltration, there was an absence of any pancreatic endocrine dysfunction, including diabetes or hypoglycemia.
Conclusion
This case highlights the unusual presentation of lymphoma with significant pancreatic involvement and without the typical endocrine disturbance emphasizing the need for careful monitoring and underscoring the variability in clinical presentations of pancreatic lymphoma.

Osilodrostat is an 11β-hydroxylase inhibitor indicated for treatment of Cushing's syndrome in adult patients. Transient use of osilodrostat may lead to prolonged adrenal insufficiency, a rare adverse event worth noting. We report here the case of an 81-year-old woman who was treated with osilodrostat (20 mg/day) for five months for severe hypercortisolism secondary to ectopic ACTH secretion [midnight cortisol at 81.7 µg/dL (2–7), with ACTH at 137 pg/mL, and urinary free cortisol at 5972.1 µg/24h (20–65)]. CT scan revealed a bronchial tumour located at the lower right pulmonary lobe and enlarged adrenals. Following tumour resection (well differentiated neuroendocrine histology), osilodrostat was discontinued. One month postoperatively, basal cortisol at 8h00 was low at 2.2 µg/dL (9–22) with inadequate ACTH secretion at 40 pg/mL (<46.0) supposedly linked to previously suppressed corticotropic cells by excessive cortisol production. The patient was given accordingly a physiological replacement dose of hydrocortisone. ^{68}Ga-DOTATOC PET/CT performed six months post-surgery ruled out residual or recurrent neuroendocrine tumor and an abdominal CT scan demonstrated normal appearance of adrenals. Ten months after discontinuation of osilodrostat, the patient exhibited persistent adrenal insufficiency. Basal hormone analysis revealed markedly elevated ACTH levels (175 pg/mL) and undetectable cortisol levels this time in favor of a residual iatrogenic effect of osilodrostat. Prolonged primary adrenal insufficiency after transient use of osilodrostat is a rare but serious side effect. Only few cases have been documented in the past two years. The underlying pathophysiological mechanism remains unclear and quite unexpected, considering the short half-life of the drug. Clinical follow up and continued adrenal function monitoring are advisable following osilodrostat discontinuation to prevent adrenal crisis in those rare at-risk patients.

Persistent virilization in a woman with CAH under medical treatment: a hidden culprit

Francesco Padovano Sorrentino[1], Antonella Giampietro[1], Sabrina Chiloiro[1], Laura De Marinis[1], Antonio Bianchi[1] & Alfredo Pontecorvi[1]
[1]Fondazione Policlinico Universitario A. Gemelli IRCCS, Endocrinolgy, Rome, Italy

Introduction
Congenital adrenal hyperplasia (CAH) is due to enzyme deficiencies, most frequently of the enzyme 21-hydroxylase, leading to increased synthesis of adrenal androgens associated, in severe forms, with adrenal insufficiency. In women, this condition manifests clinically with signs of virilization or hyperandrogenism. Leydig cell tumors of the ovary are extremely rare androgen-secreting tumors, and there are very few cases described in the literature of women with CAH who developed this tumor.
Case report
We present the case of a 59-year-old woman who came to our attention for effluvium capillorum. In remote pathological history she had post-surgical hypothyroidism for benign multinodular goiter on levothyroxine replacement therapy. Menopause since 2017. Nulliparous. On hormonal examinations she presented: 17-OH-progesterone 87 ng/ml, testosterone 1.78 ng/ml, ACTH 33 pg/ml, cortisol 205 ng/ml, DHEA-S 0.7 ng/ml, 17-beta-estradiol 30 pg/ml. In light of 17-OH-progesterone values a standard ACTH stimulation test was performed with findings of: basal 17OH progesterone 15.4 ng/ml, at 30 minutes 66.9 ng/ml, at 60 minutes 85.8 ng/ml; basal DHEAS 1266 ng/ml, at 30 minutes 1224 ng/ml, at 60 minutes 1302 ng/ml. An MRI of the abdomen was also requested, which showed no findings suspected for adrenal adenomas. Genetic testing was then requested, which led to the diagnosis of 21-hydroxylase deficiency by compound heterozygosity in the CYP21A2 gene: for the classical mutation in one allele (p.Arg357Trp), for the nonclassical one in the other (p.Val282Leu). After that, the patient started suppressive corticosteroid therapy with

modified-release hydrocortisone 10 mg in the evening and 5 mg in the morning resulting at control after 4 months in: ACTH <5 pg/ml, cortisol 162 ng/ml, 17-OH progesterone 6.9 ng/ml, testosterone 1.78 ng/ml, 17-beta-estradiol 44 pg/ml, DHEA-S 231 ng/ml, androstenedione 10.2 ng/ml. Due to persistence of elevated testosterone values despite optimized medical therapy, the situation was further investigated by transvaginal pelvic ultrasound, which showed a 27x25x15mm cystic formation at the right ovary. After consultation with the gynecologist and collecting the patient's consent, hystero-annessiectomy surgery was performed: histological examination on surgical piece then revealed a stage IA ovarian Leydig cell tumor. At the last follow-up, 2 months after surgery, the patient presented a hormonal picture of normalization of testosterone levels.
Conclusions
The present case highlights the difficult differential diagnosis of hyperandrogenism in women. Moreover, although there is limited literature to support it, it lays the foundation for the association between CYP21A2 mutations and the augmented incidence of germ cell tumors.

Peroperatory isotopic detection and mini invasive surgery, what prospects?

Redhouane Longo[1] & Mourad Benrabah[1]
[1]Regional University Military Hospital, Oran, Algeria

Introduction
The interest of minimally invasive surgery is that it is selective with significant reduction in operating time. The contribution of the peroperative detection in this case is equivalent to the contribution of a torch in a black tunnel.
Objective
Demonstrate the value of intraoperative detection in minimally invasive surgery. The scope of application of intraoperative detection in nuclear medicine:On the technical level, intraoperative detection requires the localization by an isotope of the mass to be operated, then in intraoperative use a sensor probe that allows selective resection. Nuclear medicine has several applications in this field:
*Parathyroid adenoma
*sentinel lymph nodes
*para ganglioma
*osteoid osteoarthritis
*Metastatic adenopathy of thyroid papillary carcinoma.
Discussion
The added value of this isotopic technique compared to conventional surgery alone: Surgery is an essential pillar of the treatment of focused tumors, but its success depends on the complete depletion of tumor cells during surgery. The intraoperative detection of tumor cells is therefore a means to significantly improve the results of surgery in post-operative simple surgical suites or reduce hospitalization. Intraoperative detection should have a wider role, in particular through the promulgation of nuclear medicine techniques and the training of trained teams, what will have an impact on the quality of Management of patients in terms of aesthetics with a reduction in operating time and especially the complications related to an enlarged surgical gesture.
Conclusion
In Algeria, intraoperative detection has been used for about twenty years, it has demonstrated its contribution and its usefulness in association with surgery, especially at the major senology centers of Algiers (CPMC) Nevertheless, it is difficult to find its place in daily life in association with surgery.

Bilateral gynecomastia unveiling an adrenal cortical tumor

Fatma Ben Abdessalem[1], Hamza Elfekih[1], Imen Halloul[1], Wiem Saafi[1], Sawssen Mrad[2], Younes Derbel[1], Taieb Ach[2], Salima Ferchichi[2], Ghada Saad[1] & Yosra Hasni[1]
[1]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Endocrinology Diabetology Department, 4000, Sousse, Tunisia, Sousse, Tunisia; [2]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Biochemistry Department, 4000, Sousse, Tunisia, Sousse, Tunisia

Introduction
Adrenocortical carcinoma (ACC) is an exceptionally rare malignancy. It may be classified into functioning and non-functioning types. Estrogen-secreting ACC is exceedingly rare, representing 1% to 2% of all ACCs. In men, estrogen excess manifests as gynecomastia, decreased libido, and hypogonadotropic hypogonadism. This report describes a rare case of estrogen-secreting ACC in which bilateral gynecomastia was the predominant clinical feature.
Case Presentation
A 45-year-old male presented to our department with bilateral gynecomastia, accompanied by a 6 kg weight loss, fatigue, anorexia, abdominal pain, erectile dysfunction, and decreased libido over three months. Physical examination revealed facial erythema, bilateral grade II gynecomastia, and a palpable 20 cm abdominal mass located in the left flank and extending to the epigastric and umbilical regions. Laboratory findings included testosterone at 2.97 ng/mL associated with elevated estradiol (169 pg/mL), suppressed FSH (0.3 mIU/mL), and elevated lactate dehydrogenase. TSH, FT4, prolactin and hCG levels were in the normal range. Abdominopelvic CT-scan identified a large (23×20×13 cm) left retroperitoneal mass with heterogeneous enhancement, necrosis, and calcifications, closely associated with the stomach, duodenum (D4), left kidney, and left renal vein. A low-dose dexamethasone suppression test confirmed ACTH-independent Cushing's syndrome with non-suppressed cortisol at 103.68 ng/mL and low ACTH level at 0.87 pg/mL. The patient was referred for extensive adrenalectomy with lymph node dissection.
Discussion
Feminizing adrenal tumors are rare, and hyperestrogenemia typically arises from peripheral androgen conversion. However, in this case, it is suggested that estradiol is directly secreted by the tumor. Histopathology remains the gold standard for ACC diagnosis, and surgical resection is the primary curative treatment. Adjuvant therapies are tailored to tumor grade, stage, and patient-specific factors. This case underscores the importance of considering ACC in males presenting with gynecomastia and highlights the need for prompt diagnostic evaluation and multidisciplinary management.

A diagnostic dilemma: revisiting the utility of selective arterial calcium stimulation testing for localization of occult insulinoma

Carlo Casipit[1], Bruce Casipit[1] & Maxim Barnett[1]
[1]Jefferson-Einstein Hospital, Philadelphia, United States

Background
Insulinoma is a rare neuroendocrine tumor with an incidence of one to four per million per year and its rarity can be partially attributed to diagnostic difficulties that even experienced physicians can face.
Case presentation
A 22-year-old nondiabetic male with a history of recurrent hypoglycemia with unknown etiology was brought to the hospital after being found down. At the scene, he was found to have a glucose level of 20 mg/dL by EMT and was given intravenous Dextrose 50% with improvement of mentation. He is nonalcoholic, has no known Liver or kidney disease, has no family history of diabetes, and is not on any medications. In the hospital, vital signs were normal. Physical examination was unremarkable. Laboratory tests were normal except for recurrent episodes of hypoglycemia confirmed with 72-hour fasting associated with diaphoresis and tremors relieved by glucose intake. Endocrinology was consulted and hypoglycemia testing showed elevated C-peptide 2.61 ng/mL (ref 0.5-2 ng/mL) and insulin level 31.2 uIU/mL (ref <15 uIU/mL), with normal Beta-hydroxybutyrate 0.08mmol/l (ref <0.49 mmol/l), Insulin antibody <0.4 nU/mL (ref <95 nU/mL), IGF-2 406 ng/mL (ref 265-616 ng/mL), IGF-1 209 ng/mL (ref 115-307 ng/mL), morning cortisol 18.5 mg/dL (ref 14-20 mg/dL), and negative Sulfonylurea test. Abdominal MRI and Endoscopic Ultrasound showed no pancreatic mass. A Selective Arterial Calcium Gluconate Stimulation Test (SACST) was done, which showed a fourfold increase in insulin level in the Gastroduodenal and Superior mesenteric arteries, indicating a tumor in the head or neck of the pancreas. He was started on diazoxide which improved his glucose, and he was discharged with outpatient planning for surgical exploration of the pancreas.
Discussion
Preoperative localization of insulinoma is vital since it dictates surgical success. However, current radiographic methods have low sensitivity which can have deleterious implications. SACST is 95-100% sensitive in diagnosing insulinoma as small as 2cm. Kam *et al* showed that out of forty-five biopsy-proven insulinomas, SACST definitively localized thirty-eight cases. This was concordant with Won *et al* where SACST definitively localized nine out of ten cases of insulinoma. It is also safe with no significant adverse events aside from mild nausea and skin flushing.
Conclusion
SACTS can be considered a safe and sensitive diagnostic procedure for localizing insulinomas when conventional imaging is nondiagnostic and can potentially improve clinical and surgical outcomes.

Sporadic medullary carcinoma: case report

Tamara Dojcinovic[1], Jelena Malinovic Pancic[1] & Aleksandra Markovic[1]
[1]University Clinical center of the Republic of Srpska, Medical faculty, University of Banja Luka, Banja Luka, Bosnia and Herzegovina

Medullary thyroid carcinoma is a rare tumor derived from parafollicular cells. Sporadic medullary carcinoma is usually diagnosed as advanced disease because most patients present as a solitary nodule without other signs and symptoms. 70% of patients present with neck metastases, whereas 10% of patients have distant metastases. We will present the case of a 72-year-old female with medullary carcinoma who was initially referred for operative treatment due to multinodous goiter. Upon admission to our institution, in laboratory results we found calcitonin 55810 pg/ml, CEA 1346,1 ng/ml, with normal values of parathyroid and thyroid hormones. A CT scan of the neck was performed, and the voluminous right lobe of the thyroid with hypodensity and calcifications in the lower aspects, sized 38x26x71 mm, was found, as well as conglomerates of pathologically altered lymph nodes. Total thyroidectomy with extended neck dissection was performed. Postoperative PET/CT with 18F DOPA showed secondary deposits localized supra and retroclavicular. Control calcitonin 3 months after the operation was 653 pg/ml, CEA 62 ng/ml, with normal PTH and normal catecholamines in 24h urine. The patient was reoperated on and altered lymph nodes were extirpated. In the further course, high calcitonin and CEA values were maintained, while PET/CT 18F DOPA one year after operative treatment indicated infracm pathological lymphatics. Although patient presented in older age and with exceptionally high calcitonin and CEA values, this is locoregional disease without clinical features of MEN syndrome, only active surveillance is indicated in futher follow up.

Unusual case of prolactinoma mimicking stroke

Mariam Orjonikidze[1], Natia Margvelashvili[1] & Nino Kraveishvili[1]
[1]Tbilisi institute of medicine, David Tvildiani medical university, tbilisi, Georgia

Introduction
Pituitary tumors more specifically prolactinomas, causing elevated serum prolactin, can lead to symptoms like galactorrhea, menstrual irregularities, and neurological issues, sometimes increasing the risk of stroke. This case demonstrates a patient with elevated prolactin levels and stroke mimics (non-vascular conditions that present with symptoms similar to stroke.)
Case report
A 62-year-old male has been hospitalized for dizziness, loss of coordination, motor aphasia, right-sided weakness and numbness in the face. The healthcare professionals diagnosed acute stroke: determined patient eligibility for Intravenous thrombolysis, included a contrast-enhanced CT angiography (CTA), which showed no signs of ischemic or hemorrhagic stroke and alteplase was administered intravenously. The patient's neurological impairment has not improved. An MRI of the brain revealed only a 1.6 cm hypophysial incidentaloma, prompting further investigation of prolactin levels. The patient's prolactin level was found to be 18 times above the normal range. Based on these findings, a diagnosis of prolactinoma was made. The patient was started on cabergoline therapy (0.5 mg twice weekly), which resulted in a complete resolution of his neurological symptoms within several months. After initiation of treatment prolactin level normalized.
Conclusions
This case highlights the importance of considering prolactinomas in the list of stroke mimics. This case demonstrates that elevated prolactin levels can cause neurological manifestations independently. Although prolactinomas can be a risk factor for stroke.

Great response to mitotane in advanced adrenocortical carcinoma

Maria Elena Aloini[1], Roberta Maggio[1], Pina Lardo[1], Iolanda Matarazzo[2] & Antonio Stigliano[1]
[1]Sapienza University of Rome, Rome, Italy; [2]Sant'Andrea University Hospital, Rome, Italy

Adrenocortical carcinoma (ACC) is an aggressive tumor. 5-year overall survival (OS) for advance disease is $<15\%$. However, cases of long-term disease stabilization have been reported. Mitotane monotherapy is usually reserved for biologically less aggressive tumors. A partial response (PR) rate to mitotane monotherapy of 13-31% has been reported. Typically, responses are observed when mitotane plasma levels are >14 mg/l, but sometimes PR and complete responses have been reached with lower levels. Currently, we cannot precisely define the biological characteristics of the disease and accurately predict the prognosis. In particular, no clinical or pathological factor has been validated to predict the response to mitotane monotherapy. We describe the case of a 45-year-old patient had an abdominal CT scan revealing a left adrenal mass of 15x16 cm, encompassing the ipsilateral kidney. Forty days later, the lesion measured 20 cm and extended into the contralateral adrenal lodge with para-aortic lymphadenopathy, pulmonary embolism, and multiple bilateral pulmonary nodules compatible with an aggressive metastatic ACC. A PET-FDG scan confirmed increased uptake in the left adrenal glands (SUV 12). After only 4 months, after mitotane treatment, a 45% reduction of the primary tumor and regression of lung metastases was observed, despite plasmatic drug levels of 5 mg/l. Subsequently, a further reduction in the size of the pulmonary nodules and the left adrenal mass (8x6 cm; 60%) was observed making surgical resection of the primary tumor feasible. Histology confirmed the ACC diagnosis. Mitotane represents an extremely effective therapy, also for aggressive tumors and despite plasma levels <14 mg/l.

A bilateral vestibular schwannoma in neurofibromatosis type 2

Nawres Bouaziz, Sabrine Farhani, Rachida Bouatay, Nour Kraiem, Mehdi Ferjaoui, Amel Elkorbi, Naourez Kolsi, Harrathi Khaled & Jamel Koubaa[1]
[1]ENT Department Fattouma Bourguiba Hospital, Monastir, Tunisia

Introduction
Neurofibromatosis 2 (NF2) is a dominantly inherited tumor predisposition syndrome caused by mutations in the *NF2* gene on chromosome 22, with a family history. Affected individuals inevitably develop schwannomas typically affecting both vestibular nerves leading to deafness. Schwannomas also occur on other cranial nerves, on spinal nerve roots, and on peripheral nerves. Meningiomas and ependymomas are other tumor features. Our objective is to report a rare case of a bilateral vestibular schwannoma associated with neurofibromatosis type 2.
Case Report
The patient was a 38-year-old male with no previous pathological family history of note. He presented with bilateral deafness for 5 years associated with tinnitus without neurological signs. The ENT examination was normal. Audiometric examinations and the Brainstem Evoked Response (BER) test showed right cophosis and sensorineural deafness at 70 dB on the left side. The patient was diagnosed on Magnetic Resonance Imaging (MRI) with a bilateral vestibular schwannoma measuring 14x10 mm on the right side grade 2 and 22x15 mm on the left side grade 3, filling the pontocerebellar cisterns and presenting an intrameatal extension, associated with six extra-axial expansive processes corresponding to supratentorial neurofibromas. A genetic investigation was performed and the diagnosis of neurofibromatosis type 2 was made. The patient was proposed for Gamma Knife radiosurgery.
Discussion/Conclusion
The NF2 is a rare disease characterized by bilateral acoustic neuromas or central nervous system tumors. This syndrome should be known because it can cause rare

endocrine manifestations linked to hormonal disorders or tumors that affect the endocrine glands. NF2 represents a difficult management problem. Surgery remains the focus of current management, although watchful waiting and occasionally radiation treatment have a role. In the future, the development of tailored drug therapies aimed at the genetic level are likely to provide huge improvements for this devastating, life limiting condition.

An atypical presentation of a patient with neuroendocrine tumor

Irida Kecaj[1], Ergita Nelaj[1], Athina Papadhopullo[2], Ilir Gjermeni[1], Kei Xhixhabesi[1] & Ina Refatllari[3]
[1]University Hospital Center "Mother Teresa", Internal Medicine, Tirana, Albania; [2]University Hospital Center "Mother Teresa", Department of Oncology, Tirana, Albania; [3]University Hospital Center "Mother Teresa", Department of Cardiology, Tirana, Albania

Introduction
Most neuroendocrine neoplasms are indolent and slow-growing tumors, and given the rather slow progress, some lesions are incidentally discovered as metastatic deposits rather than primary masses. Neuroendocrine tumors of unknown primary site are not so uncommon in the clinical practice and may constitute 12–22% of NEN patients. In these cases, a biopsy is often taken to allow the pathologist to identify the tumor type and possibly the primary tumor site via microscopic examination. Neuroendocrine tumors are classified according to histologic differentiation and grading system, with low-grade, well-differentiated tumors having a more indolent course, while high-grade, poorly differentiated neoplasms are rapidly growing and aggressive, which are closely related to clinical presentation and prognosis.
Case presentation
A 74-year old female hospitalized at internal medicine service due to difficulty in breathing during minor physical exertion, thoracic-abdominal discomfort, edema of the inferior sides, after exclusion of pulmonary thromboembolism with pulmonary angio-CT and acute coronary syndrome in emergency department. Abdominal echo raised the suspicion of cholecystic tumor with multiple hepatic metastases. Subsequent examinations with contrast CT and MRI abdomen, EGD and colonoscopy result in multiple secondary hepatic lesions and cholecystic calculi. CT-guided biopsy and immunohistochemical stain of the liver mass showed poorly differentiated small cell carcinoma with stain positive for PanCK+, Chromogranin+, Ki67 70%, CD56+. Since all the performed examinations were not able to identify a primary source of the tumor, after the oncological evaluation chemotherapy treatment with cisplatinium and etoposide for stage IV small cell NET of unknown primary site with metastasis to liver was recommended. Given the extent of the disease, the patient chose palliative treatment
Conclusions
In cases of neuroendocrine tumors with well-differentiated cells, more detailed diagnostic examinations are performed to find the primary site, with the goal of performing surgical intervention or starting systemic therapy depending on location. Location of primary site is also important in determining the prognosis of neoplasia. In the case of poorly differentiated neoplasms, detailed diagnostic investigations to identify the primary source do not affect the prognosis of the disease. Poorly differentiated neuroendocrine neoplasms, including small cell NET, are treated with platinum based agents regardless of where the primary site is located. In the case of poorly differentiated neoplasms.

Risk factors and malnutrition in colorectal cancer patients: identification and clinical implications

Rezgui Mohamed Amine [1], Rym Ben Othman[1], Ramla Mizouri[1], Berriche Olfa[1], Rachdi Rim[1], Jamoussi Henda[1], Mahjoub Faten[1], Belguith Jihed[1] & Mansour Sabrine[1]
[1]National Institute of Nutrition and Food Technologies, Tunisia

Introduction
Colorectal cancer (CRC) is a public health problem. The aim of this study is to determine the relationship between nutritional and environmental risk factors and the onset of CRC.
Methods
This was a retrospective study conducted among 50 CRC patients recruited from the gastroenterology and surgery departments of La Rabta Hospital in Tunisia, as well as 50 randomly selected controls. The two groups were matched for age and gender. A questionnaire was used to collect data on personal and family medical history, clinical data regarding CRC and its treatment, as well as anthropometric measurements and biological tests. A frequency questionnaire and a 24-hour recall were performed.
Results
There was a female predominance among our patients ($n=$ 26, 52%). The age of the patients ranged from 29 to 84 years, with a mean of 56.06 $\pm$ 14.24 years. Tobacco and alcohol consumption were higher among patients than controls, but this difference was not statistically significant ($P = 0.1$ and $P = 0.18$, respectively). Significant risk factors included obesity ($P = 0.02$), menopause ($P = 0.006$), as well as high consumption of red meat ($P = 0.002$), processed meat ($P = 0.002$), fried foods ($P = 0.0001$), and sugar ($P = 0.0001$). Consumption of green tea ($P = 0.003$), fruits ($P = 0.001$), and cereals ($P = 0.0001$) was higher among controls. Anorexia was nearly constant. Malnutrition was common, measured by BMI, percentage of weight loss (42%), albumin levels (60%), and various nutritional scores (NRI, MUST, MNA, and SGA). Energy and protein intake were below recommended needs for 94% and 92% of patients, respectively. Deficiencies in minerals, vitamins, and trace elements were observed.
Conclusion
A sedentary lifestyle and inappropriate dietary choices were higher in CRC group. Malnutrition was frequent in cancer patients. We suggest a screening for malnutrition in all CRC patients.

Lung neuroendocrine tumours: clinical aspects and methods of investigation

Redhouane Longo[1], Mourad Benrabah[1], Mohamed El Horri[2] & Mounia Gharnouti[1]
[1]Regional University Military Hospital, Oran, Algeria; [2]Military University Hospital Specialized in Orthopedic Surgery Rehabilitation and Orthoprosthetics, Algiers, Algeria

Introduction
Neuroendocrine tumours (NETs) are tumours that can occur throughout the body, generally affecting the digestive tract and lungs, and are characterised by their ability to secrete hormones. Rare tumours; their annual incidence is estimated at 2 to 5 new cases per 100,000 people per year, with the most affected age group being between 40 and 60. In this presentation, we report the case of a small cell lung cancer revealed by hepatalgia.
Observation
This 73-year-old patient, a 30-year smoking cessation, and type 2 diabetes mellitus on oral anti-diabetic, was admitted to our clinic for an etiological diagnosis of a NET objectified by abdominal MRI following 03 months of abdominal pain which revealed the presence of a suspicious hepatic nodule. Anapathological examination of a biopsy was consistent with a small cell NET hepatic metastasis. Immunohistochemistry was positive for anti-CgA antibodies, anti-Synaptophusin antibodies and 80% anti-Ki67 antibodies. A thoraco-abdominal CT scan revealed a pulmonary condensation systematised in the right middle lobe, with multiple secondary hepatic and mediastinal localisations. An octreoscan performed revealed a somatostatin receptor expressing lung neoplasia at the stage of lymph node and liver metastases. The patient had undergone bronchial fibroscopy with biopsy of the right middle and lower lobes, the results of which were in favour of a histopathological appearance and immunohistochemical profile of a small cell lung cancer.
Discussion-Conclusion
The NETs diversity of symptoms and their rarity present a major challenge for healthcare professionals. between the main types of lung cancer, 4 major histological types alone account for 95% of cases: [squamous cell carcinomas, adenocarcinomas, large cell carcinomas (classified as non-small cell carcinomas)] , and small cell carcinomas. The therapeutic approach depends on the nature of the tumour, ranging from chemotherapy to specific management: targeted therapy.

Molecular docking analysis of endocrine disruptors at the androgen receptor's ligand-binding domain

Reinaldo Röpke Junior[1,2], Sunday Amos Onikanni[2,3], Pedro de Sena Murteira Pinheiro[3,4] & Leandro Miranda-Alves[1,2,3]
[1]Federal University of Rio de Janeiro, Faculty of Medicine, Postgraduate Program in Endocrinology, Rio de Janeiro, Brazil; [2]Federal University of Rio de Janeiro, Institute of Biomedical Sciences, Laboratory of Environmental Endocrinology (LEEx), Rio de Janeiro, Brazil; [3]Federal University of Rio de Janeiro, Institute of Biomedical Sciences, Postgraduate Program in Pharmacology and Medicinal Chemistry, Rio de Janeiro, Brazil; [4]Federal University of Rio de Janeiro, Institute of Biomedical Sciences, Laboratory for the Evaluation and Synthesis of Bioactive Substances (LASSBio), Rio de Janeiro, Brazil

Introduction
Androgen hormones play a central role in the development and maintenance of male reproductive functions by interacting with the androgen receptor (AR). The AR regulates the transcription of genes associated with sexual differentiation, development of secondary characteristics, and tissue homeostasis. This protein comprises four main domains: the amino-terminal domain, DNA-binding domain, hinge region, and ligand-binding domain (LBD). The LBD is responsible for interactions with steroid hormones, drugs, and xenobiotic molecules, such as endocrine disruptors (EDs). EDs are environmental compounds capable of mimicking or antagonizing natural hormones, thereby affecting endocrine pathways. Some EDs, such as Bisphenol A, Tributyltin, MEHP, and Atrazine, have been shown to interact with the AR's LBD, modulating its function and altering physiological processes involving androgens. However, further exploration of the molecular interactions between EDs and the AR's LBD is still required. Molecular docking models represent a promising approach to investigate the extent of these interactions and establish correlations with the disruptive potential of various EDs on reproductive functions.
Objective
To evaluate the type and affinity of interactions between different EDs and the amino acids of the AR's LBD using molecular modeling tools.
Methodology
Ten EDs and ten known agonists with androgenic or anti-androgenic activity were selected. The three-dimensional structures were obtained in mol2 format from the PubChem and ChEMBL databases. The three-dimensional model of the AR's LBD was derived from crystallographic structures available in the PDB. Molecular docking studies were conducted using the GOLD software, employing the GoldScore scoring algorithm for result validation. The stability of the complexes was assessed by measuring hydrophobic interactions, hydrogen bonds, and dipole-dipole interactions using PyMOL and Discovery Studio.
Results
The most relevant amino acids for the stabilization of the reference agonists identified were T877, N705, R752, and Q711. Certain EDs, such as DBP, MEHP, BPS, and BPA, showed strong similarities in their interactions with these polar residues. In contrast, Irgarol, Tributyltin, and DDT demonstrated stabilization through predominantly nonpolar interactions involving M745, L704, L873, and W741. Although these interactions are less frequently described in the literature, the resulting conformations were structurally stable, suggesting an alternative modulation potential for the receptor.
Conclusion
This study contributes to the understanding of the interactions between EDs and the AR's LBD. Docking analysis indicated that different classes of EDs may exhibit varied interaction profiles with LBD amino acids, highlighting the need for further studies to evaluate their functional and toxicological impacts.

Exposure to endocrine disruptors in the NICU: the chemical footprint in premature newborns

Paula Sol Ventura Wichner[1], Marta Ocaña[1,2], Sandra Callejas[3], Roser Porta[2], Anna Carbo[3] & Ethel Eljarrat[3]
[1]Institute for Health Science Research Germans Trias i Pujol (IGTP), Pediatrics Department, Badalona, Spain; [2]Germans Trias i Pujol Hospital, Pediatrics Department, Badalona, Spain; [3]Consejo Superior de Investigaciones Científicas (CSIC), Barcelona, Spain

Introduction
Endocrine disruptors (EDCs) are chemical compounds capable of altering hormonal balance, which can lead to adverse health effects. Within this group, phthalates, organophosphate esters (OPEs), and parabens are widely used in medical devices and personal care products. The European Chemicals Agency (ECHA) has identified them as substances with endocrine-disrupting potential, either confirmed or under evaluation. Due to their biological immaturity and rapid development, premature newborns are particularly susceptible to exposure to these chemicals, which could have short- and long-term health implications.
Objectives
The aim of this study is to determine the presence of phthalates, OPEs, and parabens in urine samples from preterm newborns admitted to a Neonatal Intensive Care Unit (NICU). To achieve this, highly precise analytical methodologies are employed to assess potential exposure risks and their relationship with environmental factors within the hospital setting.
Methodology
Urine samples were collected from premature patients throughout their hospitalization in the NICU and analyzed using high-resolution liquid chromatography coupled with time-of-flight mass spectrometry (LC-QTOF). Sample preparation was carried out using the QuEChERS protocol, designed for the extraction, identification, and quantification of EDCs in biological matrices.
Results
A total of 48 urine samples from 24 neonates (8 girls and 16 boys) were analyzed, with a mean gestational age of 31.5 weeks ($\pm$2.8) and a birth weight of 1518 g ($\pm$393), corresponding to a z-score of -0.45 ($\pm$1.07). Among the evaluated compounds, OPEs showed the highest concentrations (25.9 $\pm$ 31.5 µg/l), followed by phthalates (24.9 $\pm$ 19.9 µg/l), whereas parabens, despite being detected more frequently, were found at lower concentrations (1.91 $\pm$ 3.48 µg/l). This finding aligns with NICU policies restricting the use of topical products such as creams or gels during the first three weeks of life. Additionally, an inverse relationship was identified between gestational age and the levels of these compounds, suggesting that exposure may be influenced by the hospital environment and the types of materials used at different stages of neonatal care.
Conclusions
Although the detected levels of phthalates, OPEs, and parabens in hospitalized newborns do not appear to pose an immediate health risk, it is crucial to establish continuous monitoring strategies and exposure reduction measures in hospital settings such as the NICU. Identifying additional risk factors, such as the composition of medical materials used, could help minimize associated adverse effects. These findings emphasize the need to develop stricter regulations regarding the use of chemical additives in medical and hospital environments.

Tracking endocrine disruptor effects of chlorobenzenes in AVP and OT mediated processes in Wistar? rat models

Krisztian Sepp[1], Anna László[2], Zsuzsanna Valkusz[3], Marianna Radács[4], Marta Galfi[4] & Zsolt Molnár[4]
[1]Deparment of Internal Medicine, University of Szeged, Szeged, Hungary; [2]Department of Applied Statistics, Institute of Mathematics and Basic Science, Hungarian University of Agriculture and Life Sciences, Budapest, Hungary; [3]Department of Internal Medicine, University of Szeged, Szeged, Hungary; [4]Institute of Applied Health Sciences and Environmental Education, Department of Environmental Biology and Education, Juhász Gyula Faculty of Education, University of Szeged, Szeged, Hungary

It has been experimentally demonstrated that exposure to endocrine disruptor chlorobenzenes (ClB) alter behaviour by increasing anxiety and aggression in male Wistar rats. Little is known about the effects of chlorobenzene on females, but research showing strong maternal aggression towards offspring is of particular interest. Our group aimed to investigate the background of this evidence by studying the effects of dietary route ClB exposure in animal models of neurotransmitter/hormone relapse. Our work was aimed to investigate noradrenergic and serotonergic coupled vasopressin (AVP) and oxytocin (OT) release induced by ClB exposures. In our experiments, we administered subtoxic doses of ClB mixtures (hexaClB + 1,2,4-triClB = 1:1, mixed chlorobenzenes: mClB) at doses of 0.1; 1.0; and 10.0 µg/bw.kg to Wistar ♀ rats *in vivo* via a stomach tube; 0, 30, 60, 90 days. Subtoxicity of the doses was confirmed by liver enzyme assays. AVP and OT, liver enzymes and other parameters required for assay were determined from blood samples taken according to experimental time windows. Primary monolayer cell cultures (NH) were prepared from neurohypophyseal sterile tissue samples at the end of the treatment periods. The AVP and OT separation kinetics of the resulting *in vitro* models were determined for mClB-treated and untreated NH cultures. We then followed the effects of adrenergic (norepinephrine: NE 10^{-6}M) and serotonergic (serotonin: 5HT 10^{-6}M) receptor activation on AVP and OT secretion. The results were expressed as mg protein content of the cultures. RIA procedures were used for hormone measurements.

Protein contents were measured by the modified Lowry method. Serum toxicity enzymes were measured by enzyme kinetic assays. Our results showed that mClB enhanced AVP and OT clearance in relation to treatment doses and durations. Activation of NE and 5HT neurohypophyseal receptors significantly increased AVP and OT release. Since the role of these two neurotransmitters is dominant in aggression and anxiety, the strong behavioural disturbances induced by mClB in ♀ Wistar rats may be due to NE and 5HT mediated AVP and OT secretion.

Perceptions and concerns about endocrine disruptors in the real-life of Italian family pediatricians: preliminary data of a national survey. (On behalf of ISPED Endocrine Disruptors Study Group)

Patrizia Bruzzi[1], Laura Lucaccioni[2], Viola Trevisani[2], Anna Insalaco[2], Simona Filomena Madeo[1], Barbara Predieri[2] & Lorenzo Iughetti[2]
[1]Azienda Opedaliero-Universitaria di Modena, Policlinico, University of Modena and Reggio Emilia, Modena, Italy, Department of Medical and Surgical Sciences of the Mother, Children and Adults, Modena, Italy; [2]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of the Mother, Children and Adults, Modena, Italy

Background
Endocrine disruptors (EDs) are ubiquitous pollutants, contained in common materials, from plastics to detergents. They mimic hormonal activity and interfere in the normal functionality of the endocrine system. Pregnancy and childhood are considered periods of major susceptibility. Informing families about EDs risks is now an international public health challenge and, considering the Italian health system organization, we consider family pediatricians as favored in playing this role. Therefore, this study aims to assess the current knowledge and concerns about EDs of familial pediatric healthcare professionals in Italy.
Methods
We invited family pediatricians to voluntarily respond to a short online survey on EDs (17 items) available on the website of one of the major Italian family pediatric societies (Federazione Italiana Medici Pediatri, FIMP) in August 2024.
Results
Out of more than 5300 FIMP members, only 90 completed the survey (72% working in an industrialized area). Even if 96% of interviewed pediatricians declared to be well-informed about EDs, only 33% knew specifically the materials/objects where EDs are located and the potential derived damages. Moreover, only 57% were already used to inform families about EDs and how to prevent their exposure during pregnancy, breastfeeding and childhood. When education is performed, only 10% of family pediatricians utilized predefined tools as paper and/or online information materials (e.g. brochures). The main sources of medical information were professional meeting (69% optional and 31% mandatory) and media (18%).
Conclusions
Even if preliminary, our data underline the gap of knowledge and the extreme need of specific training of the Italian familial pediatricians on this challenging topic. More effort should be directed to provide scientific information and tools to family pediatricians in order to simplify and standardize communication about the risks associated with EDs to families.

Survey of attitudes and knowledge about endocrine disruptors among the student population of the republic of Serbia

Đurica Marić[1], Katarina Baralić[1], Marijana Ćurčić[1], Danijela Đukić-Ćosić[1], Zorica Bulat[1], Biljana Antonijević[1] & Aleksandra Buha Djordjevic[1]
[1]Faculty of Pharmacy, University of Belgrade, Department of Toxicology "Akademik Danilo Soldatović", Belgrade, Serbia

Numerous studies have shown that most people lack sufficient awareness and knowledge of endocrine disrupting chemicals (EDCs) and their sources. This is primarily due to the limited information available about the chemicals in products and materials they are exposed to daily, as well as a general lack of awareness regarding the harmful effects of endocrine disruptor exposure. Being a young population that can contribute to improving the general state of awareness about these chemicals, the students' awareness of this topic is of special importance. Additionally, this population is in the reproduction phase, so their awareness and knowledge in this area can have beneficial effects on their general health as well. This study aimed to explore the awareness of the student population in the field of EDCs, their attitudes, and risk perception, as well as to assess their possible exposure to bisphenol A (BPA). Data were collected using two surveys distributed via social media. The first survey, related to knowledge and attitudes about EDCs, was completed by 352 respondents, while the second survey, related to possible exposure to BPA, was completed by 248 respondents. The largest number of respondents were between 22 and 25 years old, while the largest number of responses was received from students from medical group faculties. A statistically significant difference in the results based on gender and type of study was shown. General awareness of EDCs was low (18.4% of surveyed students had never heard of the term). Furthermore, it has been shown that student habits and behaviors can lead to potential exposure to BPA, with more than 78% of those surveyed not knowing how to reduce exposure. It has been revealed that the highest percentage of information is expected from health professionals, including pharmacists. The results of this study may help develop strategies for public education and raise awareness about EDCs and their effects on human health.

[1]Hospital Universitario Central de Asturias, Oviedo, Spain; [2]SEEP Endocrine Disruptors Working Group, Madrid, Spain; [3]Hospital del Mar, Barcelona, Spain; [4]Hospital Materno-Infantil Teresa Herrera, A Coruña, Spain; [5]Hospital Universitario San Juan de Alicante, Alicante, Spain; [6]Hospital General Universitario Dr. Balmis, Alicante, Spain; [7]Parc Taulí Hospital Universitario I3PT-CERCA, Sabadell, Spain; [8]Hospital Infanta Cristina, Parla, Spain; [9]Hospital Universitario de Cruces, Barakaldo, Spain; [10]Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain; [11]Hospital Universitario Arnau de Vilanova, Lleida, Spain; [12]Instituto de Investigación Germans i Pujol, Badalona, Spain

Introduction
Exposure to Endocrine Disrupting Chemicals (EDCs) is becoming increasingly relevant in in paediatrics due to their potential to interfere with the hormonal system and their potential effects on child development, including endocrine and neurological disorders as well as cancer risk. This study evaluates the level of knowledge about EDCs among physicians specialising in paediatrics or those whose professional activity involves paediatric care in Spain, identifying gaps in knowledge and assessing the need for continuing education on this topic.
Objectives
To evaluate the level of knowledge on EDCs among paediatricians and other specialists, identifying areas of strength and deficiency. A comprehensive understanding of this topic is essential for addressing long-term consequences and developing effective preventive strategies.
Material and methods
An observational, descriptive, cross-sectional study was conducted using a self-administered survey of physicians in Spain. The survey included questions on knowledge, exposure assessment and preventive measures related to EDCs. It was distributed through medical society newsletters, WhatsApp and social media.
Results
A total of 921 responses were obtained. According to the results, 94.7% of respondents were familiar with the term EDC and 58% consider it relevant to their clinical practice. However, 39.2% did not routinely inquire about exposure and 41.6% did not provide preventive recommendations, mainly due to a lack of training (88%). The clinical conditions that most frequently prompted recommendations to reduce exposure included pubertal disorders, obesity,

thyroid dysfunction and hyperandrogenism. The most commonly explored sources of exposure were cosmetics, drugs and food.
Conclusions
Although knowledge of the term EDC is high, its integration into clinical practice remains limited. Training and updated and consensus-based recommendations are necessary to promote the inclusion of exposure-related inquiries and preventive measures in clinical management.

Chronotypes of medical residents and their association with career choice

Mariem Souissi[1], Boubaker Fadia[1], Houcem Elomma Mrabet[1] & Oumaima Dimassi[1]
[1]Taher Sfar University Hospital, Endocrinology-Diabetology and Internal Medicine Department, Mahdia, Tunisia

Introduction
Specialty selection is a crucial step in a physician's career, influencing professional, familial, and social fulfillment. This decision is likely associated with proper synchronization with professional demands. Chronotype, defined as an individual's preference for activity and rest periods over a 24-hour cycle, may influence career choice. This study aims to explore the potential relationship between chronotypes and the specialty choices of medical residents in Tunisia.
Methods
We conducted a cross-sectional, descriptive, and analytical study in August 2024 among medical residents from Tunisian university hospitals. Participants completed an online questionnaire that collected demographic data, assessed chronotype using the Morningness-Eveningness Questionnaire (MEQ), and included questions on specialty choices and professional satisfaction.
Results
Of the 100 residents contacted, 60 completed the questionnaire, with a mean age of 27 years ($\pm$ 1.5 years). Among them, 83.3% were in medical specialties, while 16.7% pursued surgical specialties. The majority of residents (38.3%) belonged to the intermediate chronotype group, followed closely by morning-type residents (35%), while evening-type residents accounted for 26.7% of the sample. A significant correlation was observed between chronotype and specialty choice: 82% of morning-type residents opted for medical specialties, likely as a deliberate choice, compared to only 30% of evening-type residents ($P = 0.002$).
Discussion and Conclusion
Our study demonstrates that chronotype influences the specialty preferences of medical residents. Evening-type residents tend to choose specialties with flexible or predominantly nocturnal schedules, whereas morning-type residents favor disciplines with regular working hours. These findings highlight the importance of considering both biological and sociocultural preferences to better guide future physicians and improve their work-life balance.

Vitamin D deficiency during pregnancy in the presence of prenatal maternal stress and their association with the development of attention-deficit/hyperactivity disorder like symptoms in toddlers

Tamar Kacharava[1], Ketevan Nemsadze[1] & Ketevan Inasaridze[2]
[1]David Tvildiani Medical University, Tbilisi, Georgia; [2]Georgian State Teaching University of Physical Education and Sports, Tbilisi, Georgia

Introduction
Attention deficit hyperactivity disorder (ADHD) is the most common neurodevelopmental disorder in children, characterized by age-inappropriate inattention, hyperactivity, and impulsivity, which can cause extensive damage to children's academic, occupational, and social skills. Although the exact cause of ADHD remains unidentified, most researchers contend that it is a result of a combination of hereditary and environmental factors. Environmental risk factors, which mostly include psychosocial variables, pregnancy, and perinatal risk factors, are directly linked to the development of ADHD. Some studies have investigated the association between vitamin D concentrations during pregnancy and neurodevelopmental outcomes, such as behavioral problems and social competence, in the offspring. It has been proposed that vitamin D deficiency could be a risk factor for developing ADHD.
Aim
To investigate the hypothesis, that presence of prenatal maternal stress and low level of D3 vitamin in pregnancy is associated with the development of the ADHD like symptoms in toddlers ($<$ 2 years).
Materials and Methods
the study group is presented by 53 pregnant women and 53 infants of these pregnancies. A population cohort of 53 pregnant women was recruited at their 35 to 37th week of pregnancy and investigated prospectively. The participants were selected through targeted selection. Maternal experience of stressful life events was assessed by stress standardized questionnaires and maternal plasma D vitamin was measured using ECLIA method, during pregnancy. When offspring age was 6 month and then less than 2 years, mothers completed the child behavior and temperament checklist.
Results
Statistically significant relationship was identified between D3 vitamin deficit and stress level; between D3 vitamin deficit and impulsivity symptoms; between stress level and hyperactivity as well as impulsivity symptoms. But using multiple regression analysis showed that maternal stressful events during pregnancy significantly predicted ADHD behaviors in offspring and the level of D3 vitamin in this model was statistically insignificant.
Conclusion
The study don't supported the hypothesis that low level of D3 vitamin during pregnancy increases the risk of development of ADHD like symptoms in toddlers, but provides some evidence to date linking developmental vitamin D deficiency and offspring ADHD, and, if its findings are replicated, could have serious public health implications in regards to vitamin D supplementation and lifestyle behaviors during pregnancy. Although, the obtained results support the hypothesis that the influence of prenatal maternal stress causes offspring ADHD like symptoms through a programming effect.

Impact of lyposomal PC5 on rats behavioral activity

Mukhammadjon Mustafakulov[1], Tokhir Ishanhodjaev[1], Talat Saatov[1], Gulnora Artykbaeva[1], Elvira Ibragimova[1] & Zulaykho Shamansurova[1,2]
[1]Institute of Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan; [2]Central Asian University, Endocrinology, School of Medicine, Tashkent, Uzbekistan

Introduction
Oxidative stress shown as a main trigger factor of neurodegeneration in Altzheimer diseases (AD). We studied how antioxidant Liposomal-associated protein transmembrane 5 (PC5) can prevent brain neurodegeneration in rats models of AD by investigating behavioral activity.
Materials and methods
Experimental model of AD were created by intranasal injection of of $AlCl_3$ in dosage 50 mg/kg to adult rats during 7 days (AD group). Treatment group after 2h of each $AlCl_3$ injection received PC5 in dosage of 32 mg/kg were delivered in the same way (AD + PC5). Standard behavioral tests were performed in 3, 6, 9 days after treatment in AD, AD + PC5 and in control rats. Rats were sacrificed in the 10 days after experiment and tissue samples were taken flash frosen for further biochemical analysis.
Results
Rats with experimental AD presents with emotional and motosensor activity, postural instability, decreasing of walking distance, decreasing of quadrants crossing, decreasing of mink reflexes, also elongation of new labirints searching time. Decreasing of percentages of active and passive avoidance, also decreased learning coefficient for conditional reflexes. In brain tissue rats with AD content of peroxides were increased in 95%, activity of oxidative enzymes catalase, superoxide dismutase, glutation peroxide were decreased and malone dealdehyde were increased. In rats AD + PC5 group emotional and motosensor activity, quadrant crossing, new labirint searching time, also active and passive avoidance percentages were not differ from control group were not differ than in control group, except walking distance and mink reflexes. In brain tissue oxidative enzymes activity were higher, malone dealdehyde lower in compare with AD group.
Conclusion
Results suggested that PC5 significantly prevented $AlCl_{3\ \text{induced}}$ neurodegeneration in experimental AD rats evaluated by improving brain behavioural activity tests and oxidative stress enzymes activity.

Big data tools for assessing the nutritional situation of a pediatric population: did the prevalence of obesity change pre- and post-pandemic?

Ignacio Diez-Lopez[1], Sandra Maeso Mendez[2], Ioar Casado Tellechea[3], Jose A. Lozano[3] & Aritz Pérez[3]

[1]Department of Pediatrics. UPV-EHU. UD of Vitoria. Child and adolescent endocrinology. OSI Araba, Vitoria, Spain; [2]Child and adolescent endocrinology. OSI Araba, Vitoria, Spain; [3]Basque Center for Applied Mathematics, Bilbao, Spain

Introduction

To date, knowledge of population dynamics and its repercussions on health required complex, long and expensive field studies. Big data tools are nowadays postulated as a tool of first magnitude for weighted population changes observed in real time if reliable sources of collection and adequate mathematical and computer tools for their assessment are available.

Main objective

To evaluate, using big data tools, whether there have been significant changes in our pediatric population in the variables determining nutritional status (overweight) by comparing the situation before and after the pandemic, confinement and restrictions due to COVID 2019.

Material and Methods

Data collected from episodes of computerized medical records, studying the variables sex, age, weight, height, place of residence (PC, health center, neighborhood) of our population between 01/01/2020-03/31/2020 vs 01 / 01/2022-03/31/2022 To calculate the curves and percentile tables we have used the Cole-Green LMS algorithm with penalized likelihood, implemented in the RefCurv 0.4.2 (2020) software, which allows managing large amounts of data. The hyperparameters have been selected using the BIC (Bayesian information criterion). To calculate population deviations from the reference, being above 1.5 standard deviations from the mean according to age has been taken as a reference.

Results

66,975 computerized episodes of children under 16 years of age and a total of 1,205,000 variables studied are collected. Although data is available, individuals $>16^a$ are excluded due to low N. The graphs of our population are represented with respect to the standards, observing that there are differences with Orbegozo 2011 and Spain 2010. We present the data and percentages of overweight/obesity by age and sex in the two periods studied. An increase in overweight compared to the reference population is evident in the entire 2022 vs 2020 sample. But these differences are more evident in the sample of adolescent individuals and "obesity trigger" ages: 2-3 years and 6-7 years.

Conclusions

There is a significant difference in our population in the variables associated with childhood overweight if we compare the pre- and post-pandemic period, perhaps associated with confinement, less physical activity and overeating. Knowing in which areas of the population these changes have occurred, age groups, sexes or neighborhoods, will allow investing socio-health resources more efficiently. NOTE: CEIC OSI ARABA Approval Expte 2022-058

Teplizumab for type 1 diabetes in children: a paradigm shift in treatment

Husham Bayazed[1]

[1]College of Medicine University of Zakho -Kurdistan, Biomedical Science, Zakho Kurdistan, Iraq

Background and Aims

Type 1 diabetes mellitus (TIDM) in children is an autoimmune disease characterized by progressive destruction of the β cells of the pancreas and lifelong dependency on exogenous insulin. This presentation sheds light on the unique immune mechanisms of newly approved immunotherapy teplizumab and unveiling its breakthrough benefit for children with established T1DM and its impressing role in delaying the onset of the disease among high-risk relatives.

Methods

Retrieved recently published data and documented studies and trials from PubMed, Google Scholar, and the Web of Science using "TIDM and Teplizumab."

Results

Teplizumab is a newly approved humanized IgG1 kappa CD3-directed monoclonal antibody. Its exceptional design as an Fc-non-binding antibody helps to ameliorate and reduce the cytokine release syndrome associated with the adverse autoimmune destruction of pancreatic β cells in children with TIDM. It effectively stops the autoimmune destruction of insulin-producing pancreatic cells by turning off pancreatic-cell autoreactive effector CD8+ T-lymphocytes and making the cells inactive. Therefore, its mechanism seems to enhance regulatory T-cell activity and promote immune tolerance. Compared with controls, the teplizumab clinical trial was found to be an effective strategy to maintain β-cell function, reduce C-peptide decline, preserve insulin production, and reduce exogenous insulin need in children age 8 and older with new-onset T1DM for up to 2 years. More recent clinical trials concluded that the 14-day full dose of teplizumab delays the progression to clinical T1DM in high-risk individuals, resulting in reduced insulin usage and hospital visits.

Discussion

Teplizumab's unique design and its peculiar immune mechanism to enhance regulatory T-cell activity and promote immune tolerance with its recent trials for children with TIDM are intriguing and herald the start of a new and exciting era of hope in diabetes research and clinical management. Interestingly, trials in different phases revealed that teplizumab stopped β cell destruction in established TIDM and reduced exogenous insulin, delayed the disease onset among high-risk relatives, and significantly slowed progression to clinical TIDM.

Conclusion

Teplizumab is the first FDA-approved breakthrough disease-modifying immunotherapy therapy for children with TID with impressing role in delaying the onset of the disease among high-risk relatives. Despite the approval of teplizumab, the main challenges remain the need for widespread screening programs for early-stage T1DM diagnosis in children and the identification of individuals at high risk within the general population.

Keywords

TIDM, children, Teplizumab immunotherapy

Clinical features of hypercalcemic crisis due to primary hyperparathyroidism

Jaweher Kechiche[1], Abir Meherzi[1], Taieb Ach[2], Heyfa Bel Hadjmiled[1], Ghada Saad[2], Jihen Houas[1], Malika El Omri[1], Mouna Bellakhdher[1], Monia Ghammem[1], Yosra Hasni El Abed[2], Wassin Kermani[1] & Mohamed Abdelkefi[1]

[1]Farhat Hached University Hospital, ENT Head and Neck Surgery, Sousse, Tunisia; [2]Farhat Hached University Hospital, Endocrinology Departement, Sousse, Tunisia

Introduction

Primary hyperparathyroidism is a hypercalcemic metabolic disorder related to high or inappropriately normal levels of PTH. A hypercalcemic crisis. Hypercalcemic crisis, also known as parathyrotoxicosis, hyperparathyroid crisis, or parathyroid storm, is a rare but serious complication of primary hyperparathyroidism, occurring in approximately 1.6–6.7% of cases. It may have a potentially fatal course, with a mortality rate reaching up to 7%. The only cutrative treatment was the surgical removal of the parathyroid lesion. Medical management, consisting of aggressive hydration, diuretics, bisphosphonates, and calcitonin, can be used as a bridge therapy for surgery. The aim of this study was to assess clinical features of hypercalcemic crisis in primary hyperparathyroidism.

Materials and methods

This is a retrospective study conducted from January 2010 to December 2023, including all patients admitted and treated for primary hyperparathyroidism. Patients were divided into two groups: those with primary hyperparathyroidism associated with critical hypercalcemic crisis and those without hypercalcemic crisis

Results

During the study period, 80 patients were hosaitlized for primary hyperparathyroidism. Among them, 7 patients had calcium levels exceeding 3.5 mmol/dL, and 5 of these patients had critical symptoms of hypercalcmic crisis (6.25%). Polyuria and polydipsia occurred in three patients, one had acute renal injury, needed hemodialysis. Confusion or lethargy occurred in two patients, while nausea and vomiting affected all patients. One patient had acue pancreatitis (balthazar stage c). Their mean calcium level was 4.43 mmol/dL was statistically higher than the rest of cohort. Mean intact PTH value was 905.8 ng/mL. There was no differnce in preoperative imaging thechniques carried out for localization. they were treated with hydration, diuretics, and bisphosphonates. Four of them responded well to the medication. The remaining patient showed no clinical or laboratory improvement and underwent prompt parathyroidectomy. Based on the histopathological exams, the mean hyper-functional parathyroid gland size was 30,36 mm. adenoma wa observed in 4 patients and double adenoma in one case.

Conclusions
Hypercalcemic crisis is a rare but life-threatening complication of primary hyperparathyroidism that requires prompt diagnosis and management. Medical treatment, including hydration, diuretics, bisphosphonates, and calcitonin, can stabilize patients temporarily, but surgical resection remains the definitive treatment. Early identification of hypercalcemic crisis and the appropriate surgical intervention can significantly improve patient outcomes.

Parental perception and knowledge of childhood obesity: descriptive study in tunisia

Mariem Mejri[1], Asma Marzouk[1], Altaf Garbaa[1], Rahma Thabti[1], Leila Jallouli[1], Ahlem Elkefi[1], Farida Friha[1] & Asma Bouaziz[1]
[1]Ben Arous Regional Hospital, Paediatric Department, Ben Arous, Tunisia

Childhood obesity is experiencing a significant increase in developing countries, yet it is not consistently recognized as a pathological condition by parents. This study aims to assess the knowledge of Tunisian parents regarding the definition and risk factors of childhood obesity. A descriptive survey was conducted in December 2024 among 100 parents who visited the pediatric emergency department at the Regional Hospital of Ben Arous (Tunisia) with their children aged 5 to 15 years. The body mass index (BMI) of both children and their parents was evaluated using the World Health Organization (WHO) growth charts. The results revealed a prevalence of overweight and obesity in children of 13% and 2%, respectively. Among mothers, 62% were overweight or obese, with 19% having an overweight or obese child. Among fathers, 43% were overweight or obese, of whom 23% had an overweight or obese child. Alarmingly, 66% of parents did not recognize their child's overweight or obese status. Additionally, 54% of overweight or obese children belonged to low to middle socioeconomic backgrounds, and 40% of fathers and 53% of mothers had a university-level education. The majority of parents (91%) considered childhood obesity as a condition requiring medical management. However, the definition of obesity varied: 58% of parents based it on body weight, 27% on BMI, and 15% on body fat percentage. The most frequently cited risk factors were poor dietary habits (90%) and physical inactivity (89%). Nevertheless, 58% of parents underestimated the impact of maternal obesity, and 63% minimized the influence of parental obesity on their child's risk of developing obesity. This study highlights an incomplete perception of childhood obesity among Tunisian parents, underscoring the need for a targeted health education program to improve awareness of riskfactors and promote healthy lifestyle habits from an early age.

Patient preference for gender of treating endocrinologist

Eleni Kouroglou[1], Dimitra Ragia[1], Konstantinos Belis[1], Stella Proikaki[1] & Ioannis Ilias[1]
[1]Hippokration General Hospital, Department of Endocrinology, Athens, Greece

Background
There are a few studies available on patient preferences regarding physician gender. Evidence suggests that overall, both male and female patients prefer physicians of their own gender. Specific research focusing on endocrinologists is not available. This is important, since Endocrinology is predicted to become the most female-predominant subspecialty of internal medicine.
Aim
To assess whether patients have a gender preference when choosing an endocrinologist.
Methods
A survey was conducted among patients at a single endocrinology clinic. A total of 651 subjects (137 men, 514 women) had booked appointments for a consultation with endocrinologists (two women and two men) over 6 working weeks. The primary outcome was the percentage of men or women patients preferring a male or female endocrinologist. Statistical analysis was done with the Chi square test, assuming theoretical ratios of endocrine disease of 1:1 to 5:1 for women to men.
Results
According to theoretical patient ratios ranging from 1:1 to 1:5 (men to women), 12% to 34% more male patients prefer male endocrinologists compared to those who seek female endocrinologists. Conversely, 7% to 12% fewer female patients choose female endocrinologists compared to those who opt for male endocrinologists, based on a theoretical patient ratio of 1:5 to 1:1. Overall, male patients exhibit a significantly stronger preference for male endocrinologists ($P < 0.001$).
Conclusion
Medical literature indicates that both male and female patients generally prefer physicians of their own gender, a trend also observed in our Endocrinology study. Endocrinology is expected to become the most female-dominated specialty. Understanding these gender preferences is key to optimizing patient satisfaction, particularly in sensitive areas such as reproductive health and sexual development. However, addressing physician gender bias is essential and requires a cultural shift. Achieving gender equity in the medical profession will improve physician well-being, enhance retention of women physicians, and ultimately improve access to and quality of care.

Primary hyperparathyroidism and pancreatitis: a rare and multi-faceted association

Jaweher Kechiche[1], Taieb Ach[2], Abir Meherzi[1], Mouna Bellakhdher[1], Ghada Saad[2], Jihen Houas[1], Malika El Omri[1], Wassin Kermani[1], Yosra Hasni El Abed[2] & Mohamed Abdelkefi[1]
[1]Farhat Hached University Hospital, ENT Head and Neck Surgery, Sousse, Tunisia; [2]Farhat Hached University Hospital, Endocrinology Departement, Sousse, Tunisia

Introduction
The relationship between primary hyperparathyroidism and acute or chronic pancreatitis remains controversial it has been debated for decades. Hypercalcemia secondary to parathyroid hormone secretion plays a key role in the pathogenesis, although other mechanisms may also be involved. The aim of this study is to assess the prevalence, clinical presentation, and outcomes of pancreatitis associated with PHPT, emphasizing the importance of early diagnosis and management.
Materials and methods
This is a retrospective and descriptive study from January 2010 to December 2023, including all patients admitted and treated for primary hyperparathyoidism associated with pancreatitis
Results
During the study period, 80 patients were hosaitlized for primary hyperparathyroidism. Among them, 3 patients has pancreatitis revealing the disease (3.75%) with 1 recurrent acute panreatitis and 2 chronic calcifying pancreatitis. The male to female ration was ½ with mean age 57 years (54-59 years). 2 patients were diabetics. Revealing clinical symptoms were abdominal pain in all cases associated with vomiting in 1 case. Serum amylase and lipase levels were elevated. Abdominal CT scans were performed for all patients, revealing acute pancreatitis (Balthazar stage C) in one case and chronic calcifying pancreatitis in two cases. Serum calcium levels were elevated in all cases, with an average of 3.35 mmol/l(range: 2.9-3,86mmol/l). The diagnosis of PHPT was confirmed by elevated PTH levels in all cases, with a mean value of 799 pg/mL (range: 197–1920 pg/mL). Parathyroid SPECT with 99m Technetium-MIBI and ultrasound were performed for all patients, identifying a right inferior parathyroid adenoma in two cases and a left inferior parathyroid adenoma in one case. PHPT was diagnosed, and surgical treatment was planned. Surgical resection of the parathyroid adenoma was performed. The outcome was favorable in all three operated patients, with normalization of PTH and serum calcium levels. However, one patient with chronic pancreatitis experienced recurrent episodes of pancreatitis despite successful parathyroidectomy.
Conclusions
The occurrence of pancreatitis during a hyperparathyroidism is rare but it can be the only pesenting symptoms of primary hyperparathyroidism. elevated calcemia during acute or chronic pancreatitis should always get attention.

Primary hyperparathyroidism due to ectopic parathyroid lesions: our experience

Jaweher Kechiche[1], Abir Meherzi[1], Taieb Ach[2], Habiba Ben Sghaier[1], Jihen Houas[1], Ghada Saad[2], Malika El Omri[1], Monia Ghammem[1], Mouna Bellakhdher[1], Yosra Hasni El Abed[2], Wassin Kermani[1] & Mohamed Abdelkefi[1]

[1]Farhat Hached University Hospital, ENT Head and Neck Surgery, Sousse, Tunisia; [2]Farhat Hached University Hospital, Endocrinology Departement, Sousse, Tunisia

Introduction
Primary hyperparathyroidism (PHPT) is a common endocrine disorder with a prevalence of 1to 7cases per 1000 adults. In PHPT, the incidence of ectopic parathyroid glands ranges from 10% to 20%. Ectopic parathyroid adenomas arise due to abnormal migration of the parathyroid glands during embryonic development. Although ectopic parathyroid adenomas are relatively rare, they pose a significant diagnostic and surgical challenge. The atypical location of these adenomas can lead to delayed diagnosis and persistent or recurrent hyperparathyroidism following unsuccessful surgery. Standard imaging techniques such as ultrasound, SPECT-CT with 99mTc-sestamibi, and MRI. The aim of this study was to assess clinicopathological features and the effectiveness of radiological tools in localizing ectopic parathyroid adenomas in patients with primary hyperparathyroidism.
Materials and methods
This is a retrospective study conducted from January 2010 to December 2023, including all patients underwent surgery for PHPT. PHPT with ectopic parathyroid adenoma were included in this study.
Results
During the study period, 80 patients underwent surgery for primary hyperparathyroidism. Among them, 10 patients (12,5%) were diagnosed with ectopic parathyroid adenomas. The mean age of patients with ectopic adenomas was 59 years (range: 42–72 years), with a male-to-female ratio of 1:4. The most common clinical symptoms included fatigue (75%), bone pain (50%), nephrolithiasis (41%). Preoperative serum calcium levels ranged from 2.95 to 3.85 mmol/l, with a mean level of 3.42 mmol/l. PTH levels were significantly elevated, with **a**mean value of 423 ng/l (range: 180–1200 ng/l). All patients underwent ultrasound and SPECT with 99mTc-sestamibi for preoperative localization. SPECT-CT was performed in 6 cases. SPECT-CT successfully identified ectopic adenomas in 5 cases (90%). Ultrasound detected ectopic adenomas in 7 cases (70%). MRI was performed in 2 cases and successfully localized the adenoma in all. The most common ectopic locations included: Mediastinum (2 cases, 20%), Intrathyroidal (2 cases, 20%), Retroesophageal space (1 cases, 10%) Carotid bifurcation (1 case, 10%), submandibular (1 case, 10%), thymus (3 cases,30 %). After surgery, serum calcium and PTH levels normalized in 9 patients. However, 1 case of persistent hyperparathyroidism was reported due to an intrathyroidal parathyroid adenoma, which required further surgical intervention.
Conclusions
Ectopic parathyroid adenomas are a significant cause of persistent or recurrent primary hyperparathyroidism, posing both diagnostic and surgical challenges. Preoperative localization using SPECT-CT with 99mTc-sestamibi, ultrasound, and MRI plays a crucial role in identifying ectopic lesions, particularly in atypical locations.

Gender differences in specialty choices among medical residents
Mariem Souissi[1], Boubaker Fadia[1], Houcem Elomma Mrabet[1] & Oumaima Dimassi[1]
[1]Taher Sfar University Hospital, Endocrinology-Diabetology and Internal Medicine Department, Mahdia, Tunisia

Introduction
Gender disparities in medical specialty choices are well-documented but remain insufficiently explored in certain contexts. This study investigates the influence of gender on specialty preferences among Tunisian medical residents.
Methods
A cross-sectional survey was conducted among medical residents from Tunisian university hospitals. Data were collected through an online questionnaire assessing demographic characteristics, specialty choices, and factors influencing these decisions.
Results
Of the 100 residents contacted, 60 completed the questionnaire, with a mean age of 27 years ($\pm$ 1.5 years). There was a female predominance (73.3%). Among them, 83.3% were in medical specialties, while 16.7% were in surgical specialties. Our study reveals a marked distribution of specialty choices based on gender among medical residents. Indeed, 90% of male residents opted for surgical specialties, whereas only 10% of female residents made the same choice. Conversely, medical specialties were preferred by 86% of female residents, while only 14% of male residents chose them. ($P = 0.002$)
Conclusions
Gender plays a crucial role in shaping specialty preferences among medical residents. While males exhibit a strong inclination toward surgical fields, females tend to favor medical specialties. These disparities may be driven by societal norms and perceived professional and personal compatibility. Addressing these gender-based differences could help promote more equitable access to diverse career opportunities.

The night shift: impacts of delayed sleep patterns on endocrine function, growth, and puberty in adolescents
Shaymaa Elsayed[1], Dina Fawzy[1], Ashraf Soliman[2], Ahmed Elawwa[1], Fawzia Alyafei[2], Nada Alaaraj[2] & Noor Hamed[2]
[1]Pediatric Endocrinology and Diabetology Unit, Alexandria University, Alexandria, Egypt; [2]Department of Pediatrics, Hamad General Hospital, Doha, Qatar

Background
Delayed sleep patterns and the reversal of sleep-wake cycles, where children and adolescents sleep during the morning and remain awake at night, are increasingly prevalent. These disruptions can adversely affect endocrine function, growth, and development, highlighting the need for a comprehensive understanding of their physiological and developmental impacts.
Objective
To evaluate the effects of delayed sleep patterns and sleep-wake cycle reversal on growth hormone secretion, cortisol rhythms, pubertal hormones, glucose metabolism, and overall development in children and adolescents.
Methods
A systematic review of the literature published between 2000 and 2024 was conducted. A total of 12 studies, involving over 5,000 children and adolescents, were analyzed. Key studies addressing the impact of altered sleep patterns on endocrine function were identified and reviewed.
Results
Delayed sleep phase syndrome (DSPS) and delayed sleep-wake phase disorder (DSWPD) are associated with significant disruptions in endocrine function. Altered sleep patterns reduce growth hormone secretion, which predominantly occurs during slow-wave sleep, impairing linear growth and development. Cortisol secretion rhythms are disrupted, with increased evening cortisol levels impairing stress responses and metabolic functions. Pubertal hormones, including luteinizing hormone (LH) and follicle-stimulating hormone (FSH), are also affected, potentially delaying pubertal progression. Sleep disturbances also negatively impact glucose metabolism, leading to decreased glucose tolerance and insulin sensitivity. These changes may contribute to an increased risk of metabolic disorders in adolescents with persistent sleep misalignment.
Conclusion
Delayed sleep patterns and the reversal of sleep-wake cycles pose significant risks to endocrine function, growth, pubertal development, and metabolic health in children and adolescents. The misalignment of circadian rhythms disrupts critical hormonal processes, including growth hormone secretion, cortisol regulation, pubertal hormone synthesis, and glucose metabolism. Early identification and management of DSPS and DSWPD are essential to mitigate these risks and promote optimal development.

Living on the edge: war, stress, and autoimmune diabetes
Daljeet Kaur[1], Tal-Talya Avitan[1] & Ron Piran[1]
[1]Azrieli Faculty of Medicine, Bar Ilan University, Regenerative Medicine and Diabetes, Safed, Israel

Environmental stress is a known modulator of immune function and disease onset in autoimmune disorders such as type 1 diabetes (T1D). Using Non-Obese Diabetic (NOD) mice, a well-established model for T1D, we investigated the effects of sustained stress exposure in a conflict zone. NOD mice develop diabetes due to immune-mediated destruction of pancreatic β-cells, and their disease progression is influenced by external stressors. During a prolonged period of regional hostilities, we observed a significant increase in diabetes onset rates, exceeding those reported under standard conditions. Despite maintaining strict

hygiene protocols, our facility experienced frequent environmental disruptions, including power fluctuations and abrupt evacuations, leading to sustained stress exposure. Previous studies have linked stress to immune dysregulation, and our findings provide direct evidence that chronic stress accelerates T1D onset. These results highlight the profound impact of environmental stress on autoimmunity and offer insights into its potential role in human autoimmune disease progression.

University Hospital. CIBERSAM, UPV/EHU, Vitoria, Spain., Vitoria, Spain

Summary
The coincidence of COVID-19 and confinement on children's health has been studied. One possible cause of malnutrition is eating disorders. Big data tools are currently a first-rate tool for assessing population changes and possible causes.
Main objective
To assess the possible changes in the prevalence of malnutrition in a child population after having suffered the confinement of COVID-19
Material and Methods
Data collected from episodes of computerized medical records, studying the variables sex, age, weight, height, of a pediatric population comparing the situation just before COVID (2020) and after the social isolation measures were completely finished (2022) Using big data methods to study variables. Using the Cole-Green LMS algorithm with penalized likelihood, implemented in the RefCurv 0.4.2 software (2020), which allows managing large amounts of data. The hyperparameters have been selected using the BIC (Bayesian information criterion). To calculate population deviations from the reference, the reference was taken as being below 1.5 standard deviations from the average according to age.
Results
66,975 computerized cases of children under 16 years of age and a total of 1,205,000 variables studied. The data and comparative graphs between districts of the population studied are represented with respect to the variables analyzed. There is an increase in cases of malnutrition, especially in districts with specific characteristics.
Conclusions
Big data technology allows for more efficient population studies, selecting populations most in need of health intervention, optimizing scarce health resources.

Thyroid health in the age of night shifts: the role of circadian disruption

Jelena Malinovic Pancic[1,2], Tamara Dojčinović[1,2] & Tijana Icin[3,4]
[1]University Clinical Centre of Republic of Srpska, Endocrinology, Banja Luka, Bosnia and Herzegovina; [2]Medical Faculty of University Banja Luka, Banja Luka, Bosnia and Herzegovina; [3]Clinical Centre of Vojvodina, Novi Sad, Serbia; [4]Medical Faculty of Novi Sad, Novi Sad, Serbia

The thyroid gland plays a pivotal role in regulating metabolism, energy expenditure, and overall hormonal balance. As such, it is highly sensitive to disruptions in circadian rhythms, which govern the body's natural sleep-wake cycle. Circadian disruption, often seen in individuals working night shifts, can lead to significant alterations in thyroid function, with potential long-term health implications. This study investigates the effects of night shift work on thyroid health, focusing on how irregular sleep patterns influence the regulation of key thyroid hormones, including triiodothyronine (T3), thyroxine (T4), and thyroid-stimulating hormone (TSH). Night shift work interferes with the body's natural circadian rhythm, leading to misalignment between the internal biological clock and external environmental cues. This misalignment disrupts the hypothalamic-pituitary-thyroid (HPT) axis, the system responsible for regulating thyroid hormone production. As a result, night shift workers often experience fluctuations in thyroid hormone levels, which may manifest as subclinical or overt thyroid dysfunction. The study explores the underlying mechanisms that may contribute to these hormonal alterations, including changes in light exposure, sleep deprivation, and the associated disruption of neuroendocrine pathways. In addition to its effects on thyroid function, night shift work is strongly associated with an increased risk of metabolic disorders, such as obesity, insulin resistance, and type 2 diabetes. These conditions are frequently linked to thyroid dysfunction, as the thyroid hormones play a key role in regulating energy metabolism and glucose homeostasis. Disruptions in thyroid hormone levels can exacerbate metabolic disturbances, creating a vicious cycle that further impairs metabolic health. Our findings underscore the need for healthcare providers to regularly monitor thyroid function in night shift workers, as early detection of thyroid dysregulation can help prevent or mitigate the long-term consequences of thyroid disorders. Routine screening for thyroid dysfunction in this population is essential to identify individuals at risk of developing metabolic disorders. Furthermore, we advocate for the development of standardized protocols for thyroid health monitoring, particularly for individuals in occupations that require frequent or prolonged night shift work. Ultimately, improving our understanding of these relationships may help inform workplace health policies and contribute to the development of targeted interventions aimed at minimizing the negative health impacts of night shift work.

Endocrine disruptions in the kabuki syndrome spectrum

Yesmine Elloumi[1], Ekram Hajji[1], Bilel Ben Amor[1], Marwa El Arem[1], Hanen Sayadi[1] & Ines Khochtali[1]
[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Background
Kabuki syndrome is a rare condition characterized by a spectrum of features, including distinctive facial dysmorphia, skeletal abnormalities, dermatoglyphic patterns, and intellectual disability. Endocrine disorders, such as hypothyroidism or growth hormone deficiency, may also be present within this spectrum.
Case Report
We present the case of a 28-year-old woman from a non-consanguineous marriage, with a normal psychomotor development, who has been monitored for hypothyroidism since the age of 11, alongside bilateral renal lithiasis. The patient was admitted to our department for the management of profound hypothyroidism, with a TSH level of 80 µU/mL, following discontinuation of her hormone replacement therapy. Clinical examination revealed short stature (1.40 m), a weight of 52 kg, long palpebral fissures with eversion of the lateral lower third of the eyelids, prominent arched eyebrows with notched outer thirds, a short columella, and a flattened nasal tip. The patient also exhibited brachydactyly. Hormonal tests revealed a hypogonadotropic hypogonadism profile with FSH = 3 IU/l, LH = 0.3 IU/l, and estradiol = 5 ng/l. Cardiac ultrasound showed non-obstructive hypertrophic cardiomyopathy. Given this clinical presentation, Kabuki syndrome was suspected. Genetic testing is currently underway to investigate mutations in the KMT2D or KDM6A genes.
Conclusion
The diagnosis of Kabuki syndrome remains primarily clinical, though it is marked by significant clinical and biological heterogeneity. Most reported cases of Kabuki syndrome are sporadic. Despite its variability, the prognosis is generally favorable, with many individuals leading relatively normal lives.

Big data tools are currently a major tool for assessing population changes. There is a possible causal relationship between a family's economic capacity and social dystocias and malnutrition. It is also known that a possible cause of malnutrition is eating disorders, which are more frequent in populations with different levels of education.
Main objective
To assess the possible relationship between family income and prevalence of malnutrition in a child population.
Material and Methods
Using the Cole-Green LMS algorithm with penalized likelihood, implemented in the RefCurv 0.4.2 software (2020), which allows managing large amounts of data. The hyperparameters have been selected using the BIC (Bayesian information criterion). To calculate population deviations from the reference, the reference was taken as being below 1.5 standard deviations from the average according to age.
Results
The data and comparative graphs between districts of the population studied are represented with respect to the variables analyzed.
Conclusions
Big data technology allows for more efficient population studies, selecting populations most in need of health intervention, optimizing scarce health resources.

Feeding issues: an under-recognized complication in people with hyperinsulinism

Lauren Lopez[1], Tai Pasquini[1] & Julie Raskin[1]
[1]Congenital Hyperinsulinism International, Glen Ridge, United States

Background
Congenital Hyperinsulinism (HI) is the most common cause of persistent hypoglycemia in newborns and children. In HI, dysregulated pancreatic beta-cells produce too much insulin, leading to severe hypoglycemia and, in many cases, irreversible neurological damage. An under-studied and under-recognized feature of HI is feeding issues.
Aim
This study's aim was to characterize the presence of feeding issues in individuals with HI and the impact on their families.
Methods
People with HI, or their caregivers, who consented to participate in the HI Global Registry (HIGR) and completed the Diet & Feeding survey were included in this study. The survey was approved by members of the HIGR Steering Committee. All variables are categorical and are reported using descriptive statistics and chi-square tests.
Results
246 individuals were included in this survey (80% $<$18 years old). 65% reported that they had experienced feeding issues, with the most common issues reported including poor appetite (67%) and refusing to eat (59%). Individuals who reported tube feeding were significantly more likely to have experienced feeding issues than those who did not use tube feeding (chi2, $P<$ 0.001). 36% reported that feeding issues had fully resolved, and the majority reported full resolution by 6 years of age (83%). However, 63% reported feeding issues had not fully resolved, and 41% of those individuals were 7 years or older. 62% of individuals reported receiving feeding therapy, however feeding therapy did not have a significant impact on whether feeding issues resolved (chi2, P = 0.713). However, details such as the type or duration of feeding therapy were not collected in this survey.
Discussion
Feeding issues are poorly understood within the context of HI. It is unknown exactly what leads to feeding issues, although factors such as direct pathophysiology of HI, the effects of HI medications, and the psychological impacts of the heightened importance of feeding and over-feeding to prevent hypoglycemia may play a role. Many individuals with HI and their caregivers feel that feeding issues represent a major gap in the clinical management of HI. One parent commented: *"Management of feeding issues is something which I feel is horrendously lacking in HI and lack of attention and mismanagement has caused my son far more difficulties and trauma than should have needed to be the case"*. More research into the causes of feeding issues and the most effective therapies for people with HI are urgently needed.

Influence of maternal dietary protein precursor on reproductive endocrinology of neonatal bovine offspring

Jennifer Thorson[1] & Ligia Prezotto[2]
[1]USDA, Agricultural Research Service, U.S. Meat Animal Research Center, Clay Center, United States; [2]University of Nebraska – Lincoln, Lincoln, United States

Bovine oogenesis and follicular maturation are initiated during *in utero* development, a process that is stringently orchestrated by the endocrine milieu. Of paramount importance are the three major biologically active estrogens: estron, estradiol, and estriol that are involved in the development and maintenance of germ cells. Previous work using the current model have revealed that maternal urea (protein precursor) supplementation reduces the ovarian follicular reserve without compromising the number of secondary and tertiary follicles. Therefore, we did not anticipate an influence of dietary treatment on biologically active estrogens. However, as the ovarian reserve is positively associated with circulating concentrations of anti-Mullerian hormone (AMH) we hypothesized that offspring from dams supplemented urea would have reduced circulating concentrations of AMH at birth. To characterize the effects of maternal urea supplementation, multiparous cows pregnant with female calves were individually-fed isocaloric dietary treatments consisting of chopped forage top-dressed with a control (0 g urea/animal/d) or urea (80 g urea/animal/d) pelleted supplement. Diets met or exceeded dietary requirements throughout gestation. Blood samples were collected from offspring at birth for the collection of plasma. Plasma was analyzed for concentration of estradiol, estrone, unconjugated estriol, and AMH using commercially available ELISA kits. The effect of maternal dietary treatment on concentration of hormones in offspring were evaluated by ANOVA. As expected, maternal dietary treatment did not influence circulating concentrations of estradiol (P = 0.41), estrone (P = 0.35), or unconjugated estriol (P = 0.31). However, it was not anticipated that maternal dietary treatment would have no effect on circulating concentrations of AMH (P= 0.97) as offspring of urea-supplemented dams had fewer primordial and primary follicles than offspring from control dams. From these results we infer that maternal urea supplementation induces precocious follicular activation and/or increases the number of follicles recruited during maturation through an AMH-independent mechanism. Moreover, these data illustrate that while offspring of dams offered urea throughout pregnancy have a reduction in primordial and primary follicles, the steroidogenic competence of secondary and tertiary follicles is no different than dams offered the control diet. USDA is an equal opportunity provider and employer.

Calculation of risk factors in medical vs. surgical treatment for persistent hyperinsulinemic hypoglycemia of infancy: a systematic review of long-term outcomes"

Ashraf Soliman[1], Noora AlHumaidi[1], Nada Alaaraj[1], Noor Hamed[1], Shayma Ahmed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Persistent hyperinsulinemic hypoglycemia of infancy (PHHI) is a rare metabolic disorder characterized by inappropriate insulin secretion, leading to profound hypoglycemia. Long-term management strategies, aim to prevent severe neurological damage while mitigating associated complications such as diabetes mellitus and malabsorption. This systematic review examines the risk factors and outcomes associated with medical and surgical interventions for PHHI.
Methods
A systematic review of literature published between 1990 and 2025 was conducted to identify studies addressing long-term outcomes of medical and surgical treatments for PHHI. Data were extracted regarding patient characteristics, treatment modalities, and long-term outcomes, including recurrence of hypoglycemia, growth abnormalities, and neurodevelopmental risks.
Results
Fourteen studies encompassing 317 patients were analyzed. Neonatal-onset PHHI was consistently associated with more severe disease and higher risks of neurological complications compared to infancy-onset PHHI. Medical management, often using diazoxide and octreotide, was effective in approximately 40–60% of cases, particularly in late-onset and less severe presentations. However, failure of medical therapy often necessitated near-total (90–95%) pancreatectomy.

• Risk factors by treatment modality (based on figure data):
• Hypoglycemia recurrence was highest in diffuse surgical cases (50%) and medical therapy (50%), while significantly lower for focal surgical therapy (3%).
• Growth abnormalities were minimal in medical therapy (10%) and focal surgical therapy (5%) but higher in diffuse surgical therapy (20%).
• Neurodevelopmental abnormalities occurred in 50% of diffuse surgical cases, 40% of medical therapy cases, and only 10% of focal surgical therapy cases.
• Medical management: Patients treated medically exhibited lower rates of diabetes (0–25%) but experienced ongoing risks of hypoglycemia and developmental delay if treatment was delayed.• Surgical treatment: Near-total pancreatectomy resulted in euglycemia in 70–80% of cases but was associated with a 40–60% risk of diabetes and other complications, such as exocrine pancreatic insufficiency. Early surgical intervention reduced the risk of severe neurological sequelae but increased the likelihood of long-term diabetes. Laparoscopic approaches showed promise for reducing postoperative complications.Genetic factors, such as mutations in the SUR1 gene, were significant predictors of disease severity and treatment outcomes, with homozygous mutations correlating with diffuse disease and higher diabetes risks.
Conclusions
The choice between medical and surgical treatment for PHHI should consider disease severity, onset age, and genetic factors. While medical therapy is preferable to avoid diabetes and preserve pancreatic function, early surgical intervention is critical in medically refractory cases to prevent irreversible neurological damage. Long-term follow-up is essential to monitor for complications.

Neonatal vitamin D deficiency as a risk factor for the development of bronchopulmonary dysplasia: a systematic review and meta-analysis

Bernita Yeo[1], Nowel Tan[1] & Daniel Chan[1]
[1]KK Women's and Children's Hospital (Singapore), Singapore, Singapore; [2]KK Women's and Children's Hospital, Department of Paediatrics, Singapore, Singapore; [3]Duke-National University of Singapore Medical School, Singapore, Paediatrics Academic Clinical Programme, Singapore, Singapore

Background
Vitamin D deficiency is increasingly recognized as a contributor to immune dysregulation and the pathogenesis of pulmonary diseases. Vitamin D plays a pivotal role in alveolar development, and its deficiency—particularly in the neonatal period—may predispose infants to conditions such as bronchopulmonary dysplasia (BPD). This systematic review and meta-analysis aimed to evaluate the association between neonatal vitamin D deficiency and the development of BPD, with secondary outcomes including the incidence of respiratory distress syndrome (RDS), necrotizing enterocolitis (NEC), and mortality before discharge.
Methods
A systematic search of four major databases—Embase, Web of Science, PubMed, and Cochrane—was conducted to identify relevant studies. The primary outcome was the incidence of BPD, while secondary outcomes included the incidences of RDS, NEC, and mortality prior to discharge. Inclusion criteria were studies involving neonates admitted to the neonatal intensive care unit (NICU) with 25-hydroxyvitamin D levels measured at admission and outcomes of interest reported. Studies that lacked data on neonatal vitamin D status or BPD as an outcome measure were excluded. Pooled odds ratios (ORs) and corresponding 95% confidence intervals (CIs) were calculated using a random-effects model to account for heterogeneity among studies.
Results
From a total of 2,298 identified studies, 13 focused on neonatal populations, and 3 met the eligibility criteria. These included two prospective observational studies and one retrospective cohort study. Neonates with vitamin D deficiency had a significantly higher risk of BPD (OR 2.49, 95% CI 1.10–5.68), RDS (OR 2.50, 95% CI 1.21–5.17), and suspected or confirmed NEC (OR 2.55, 95% CI 1.21–5.38) compared to vitamin D-sufficient neonates. No statistically significant difference was observed in mortality before discharge between vitamin D-deficient and -sufficient neonates.
Conclusions
Findings from this systematic review and meta-analysis suggest that 25-hydroxyvitamin D deficiency is an important and potentially modifiable risk factor for the development of BPD, RDS, and NEC in neonates. These results emphasize the need for further research into the mechanistic pathways linking vitamin D deficiency with adverse respiratory and gastrointestinal outcomes in neonates. Additionally, interventional studies evaluating the potential benefits of early vitamin D supplementation in at-risk neonates are warranted. Incorporating routine vitamin D screening into NICU protocols may also help identify vulnerable populations and guide preventive strategies.

Association of early nutrition and growth and metabolic parameters in very low birth weight infants

Indre Petraitiene[1], Rasa Brinkis[2], Egle Jurgaite[1], Rasa Steponaviciute[3] & Rasa Verkauskiene[1]
[1]Lithuanian University of Health Sciences, Medical Academy, Institute of Endocrinology, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Medical Academy, Department of Neonatology, Kaunas, Lithuania; [3]Lithuanian University of Health Sciences, Medical Academy, Department of Laboratory Medicine, Kaunas, Lithuania

Aim
Impaired postnatal growth is the most important issue in very low-birth-weight (VLBW) infants. Early nutrition is one of the modifiable factors and has the greatest influence on growth. Optimal nutrients intake in this population remain unknown. The aim of this study was to evaluate nutrients intake during the first 28 days of life and its impact on growth, metabolic and hormonal profile at this age.
Methods
120 infants with birth weights below 1500 g and gestational ages below 35 weeks were included in the study. Nutrient intakes were assessed daily, and anthropometric measurements were checked weekly until 28th day postpartum. Glycaemia and hormonal levels were assessed on day 28th after birth before the meal.
Results
The mean birth weight SDS was -1.25 ± 1.44 and length SDS was -1.69 ± 1.62. The mean daily weight gain velocity in 28 days was 12.3 ± 3.5 g/day. On 28th day after birth, mean weight SDS was -2.07 ± 1.11; length SDS was -1.91 ± 1.46; ponderal index was 22.5 ± 2.3. Metabolic and hormonal parameters in 28th day were as follows (mean ± SD): fasting glycaemia - 4.72 ± 1.51 mmol/l; fasting insulin - 17.6 ± 18.0 mU/l; HOMA-IR – 4.46 ± 6.39; IGF-1 – 1.83 ± 1.19 nmol/l; IGF-BP-3 – 8.80 ± 3.20 ng/ml; IGF-1/IGF-BP-3 ratio 1,55 ± 0.82. Cumulative total energy and fat intake in 28 days (g/kg) correlated directly with IGF-BP-3 level ($r = 0.255$, $P = 0.01$ and $r = 0.263$, $P = 0.008$, respectively). Cumulative carbohydrate intake tend to be related to IGF-1 level ($r = 0.194$, $P = 0.054$). Cumulative fat intake was inversely related to HOMA-IR and glucose level on 28th day after birth ($r = 0.210$, $P = 0.036$ and $r = -0.212$, $P = 0.033$, respectively) . Cumulative carbohydrates intake was inversely related to insulin level, HOMA-IR and glucose level ($r = -0.230$, $P = 0.020$; $r = -0.275$, $P = 0.006$ and $r = -0.319$, $P = 0.001$, respectively). Cumulative protein intake was also inversely related to glucose levels ($r = -0.259$, $P = 0.009$). However, protein to total energy ratio was inversely related to IGF-BP-3 and directly to insulin levels and HOMA-IR ($r = -0.249$, $P = 0.013$; $r = 0.216$, $P = 0.031$ and $r = 0.251$, $P = 0.011$, respectively). Length SDS at on 28th day after birth was not related to nutritional factors.
Conclusion
Total energy and higher carbohydrate intake lead to higher weight gain, but did not result in unfavorable carbohydrate metabolism. Protein-rich nutrition in VLBW infants was related to higher insulin resistance 4 weeks after birth. Ethics: Approval of the study was obtained at the Kaunas Regional Bioethics Committee (approval No. BE-2-12). The study was registered at ISRCTN Database (No. ISRCTN64647571). The written consent of both parents was obtained.

Genetic characteristics and clinical management of patients with diazoxid-unresponsive congenital hyperinsulinism in Slovakia

Denisa Lobotková[1], Martina Miňová[2], Simona Tárnoková[3], Zuzana Dobiašová[4], Martina Škopková[4], Daniela Gašperíková[4] & Juraj Staník[1,4]
[1]Faculty of Medicine at Comenius University and National Institute of Childreńs Diseases, Department of Pediatrics, Bratislava, Slovakia; [2]Faculty of Medicine of the Pavol Jozef Šafárik University in Košice and Childreńs University Hospital, Košice, Slovakia; [3]National Institute of Childreńs

Diseases, Bratislava, Slovakia; [4]Institute of Experimental Endocrinology, Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia

Background
One of the critical distinguishing features of children with congenital hyperinsulinism (CHI) is diazoxid responsivness. In diazoxide-unresponsive (DU) patients molecular analysis provides information on the pancreatic histological subtype (i.e. focal vs diffuse) and determinates the most appropriate management strategy. Inactivating mutations in the ABCC8 and KCNJ11 genes are the most common, followed by mutations in GCK and HK1 gene. Recently, important advances have been made in CHI, including newly described molecular mechanisms, novel imaging techniques and therapeutic options.
Aims and objectives
The aim of this study was to evaluate genetic background and clinical management of the patients with DU-CHI in Slovakia.
Patients and Methods
Based on the data from the Slovak nationwide database of children with persistent hyperinsulinemic hypoglycaemia, 6 (22%) of 28 children with CHI were DU since 2005. In all of the individuals DNA analysis of the most common CHI genes was performed.
Results
In all of the six children with a DU-CHI a causal mutation was identified. Four children (66%) had focal form of CHI based on the paternally inherited recessive mutation, i.e. c.1332G>T (2 patients) and c.2694+1G>C in the ABCC8 gene, and c.498_502delinsAG in the *KCNJ11* gene. All of them successfully underwent partial pancreatectomy. One boy had inherited two heterozygous mutations c.154C>T and c.901C>G of the *KCNJ11* gene in the trans position, and since diagnosis is treated with somatostatin analogues. A de novo deletion encompassing the 151bp regulatory silencer region in intron 2 of the HK1 gene was detected in one girl with a severe clinical course of CHI using digital PCR (dPCR).
Conclusions
DU forms account for 22% of CHI in Slovakia. Genetic cause was identified in all six children; four had a focal form based on the paternally inherited *ABCC8* or *KCNJ11* mutations, and two children had a diffuse form based on the *KCNJ11* and *HK1* mutations, respectively. The type of mutation determinates the most appropriate treatment strategy in patients with DU-CHI, including use of somatostatin analogues and pancreatic surgery.

Objectives
Neudesin is a newly discovered protein mainly secreted from adipose tissue and the brain. It plays a role as a neurotrophic factor in the brain and a negative regulator of energy expenditure. Neurodevelopmental delay and cognitive dysfunction are common features in cases with congenital hypothyroidism (CH) without treatment. Considering neudesin's role in brain development and its contribution to the survival of mature neurons, any possible relationships between neudesin and thyroid hormone were evaluated.
Methods
A total of 52 patients (32 patients with CH, 14 females and 18 males, aged 19±7 days; 20 healthy subjects for the control group; 7 females and 13 males, aged 22±8 days) were included in the study. All patients were evaluated for thyroid hormones and plasma neudesin levels. The basal neudesin levels between the patient and control groups and the patients' neudesin levels before and after l-thyroxine treatment were compared.
Results
Regarding basal neudesin levels, there was no statistically significant difference (6.77±6.41 vs 7.93±7.04 ng/mL) ($P = 0.552$) between the CH and control groups respectively. However, neudesin levels increased following one month of therapy (6.46±6.63 vs 12.85±18.74 ng/mL) in the CH group; this difference was statistically significant ($P = 0.019$).
Conclusion
Although there was no difference in basal neudesin levels between the patient and control groups, neudesin levels increased with treatment. However, more extensive and different studies are needed to understand the pathophysiological role of this relationship in the disease or the recovery process.

Evaluation of clinical characteristics of syndromic and non-syndromic monogenic diabetes presented at neonatal and childhood period in a highly consanguineous population

Amine Aktar[1], Ruken Yıldırım[1], Şeryan Özalkak[1], Funda Feryal Taş[2], Belma Haliloğlu[3], Elisa De Franco[4], Sarah E Flanagan[4], Huseyin Demirbilek[5] & Mehmet Nuri Ozbek[6]
[1]Diyarbakır Children's Hospital, Clinics of Pediatric Endocrinology, Diyarbakir, Türkiye; [2]Gazi Yaşargil Training and Research Hospital, Paediatric Endocrinology, Diyarbakir, Türkiye; [3]Marmara University, School of Medicine, Deparmtent of Paediatric Endocrinology and Diabetes, Istanbul, Türkiye; [4]Exeter University Medical School, Department of Clinical and Biomedical Science, Exeter, United Kingdom; [5]Hacettepe University Faculty of Medicine, Department of Paediatric Endocrinology, Ankara, Türkiye; [6]Mardin Artuklu University Medical School, Paediatric Endocrinology, Mardin, Türkiye

Aim
Monogenic diabetes (MD) accounts for the underlying aetiology of a small group of diabetes cases characterized by a single gene mutation. Given its heterogeneous course, identifying the relevant gene mutation and describing its characteristics is fundamentally important for the management and genetic counselling. In this study, we assessed a large series of patients with syndromic and non-syndromic MD who presented during neonatal and childhood periods.
Methods
A total of 46 patients with syndromic and non-syndromic MD from 41 families who presented between 2010 and 2022 were included. Family history, clinical and laboratory characteristics, and molecular genetics analysis results were obtained from hospital records.
Results
A mutation was detected in 44 of 46 (95.6%) patients. In non-syndromic MD, *ABCC8/KCNJ11* mutations ($n = 6$), *INS* mutations ($n = 5$), and *GCK* mutations ($n = 5$) were the most prevalent underlying causes. PTF1A mutations ($n = 11$) and EIF2AK3 mutations ($n = 9$) were most commonly observed in syndromic MD. The rates of parental consanguinity were 64.7% in patients with non-syndromic MD and 96.3% in patients with syndromic MD ($P = 0.015$). A successful transfer from insulin to sulfonylurea (SU) therapy was achieved in 2 patients with *ABCC8* and two patients with *KCNJ11* mutations.
Conclusion
In our large cohort, we found a high detection rate of underlying genetic causes (95.6%) for neonatal and childhood-onset MD which was attributed to enrichment by the high rate of consanguinity. Biallelic and syndromic forms were highly prevalent, especially within consanguineous populations. In patients with MD who have consanguineous parents, biallelic gene mutations that cause syndromic and non-syndromic diabetes should be prioritized in molecular genetics analysis.

Managing daily challenges in congenital hyperinsulinism: impacts and solutions for improved quality of life"

Ashraf Soliman[1], Noora AlHumaidi[1], Fawzia Alyafei[1], Noor Hamed[1], Shayma Ahmed[1] & Nada Alaaraj[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Congenital hyperinsulinism (CHI) is a rare disorder caused by excessive insulin secretion, leading to persistent hypoglycemia. CHI poses significant challenges for patients and caregivers, affecting dietary, medical, cognitive, and social aspects of life. Effective strategies are essential for improving quality of life (QoL) and long-term outcomes.
Objective
To summarize the daily challenges in CHI management and propose strategies to address them, focusing on dietary, medical, cognitive, social, and long-term aspects, as well as therapeutic advancements.
Methods
A systematic review of studies published between 1990 and 2025 identified key challenges and solutions across multiple domains. Data from 16 studies were analyzed, including patient cohorts and reviews on QoL impacts and management strategies.
Results
1. Dietary Management: CHI requires frequent meals or high-protein, low-carbohydrate diets. Severe cases may need overnight feeding or gastrostomy. Personalized dietary plans and continuous glucose monitoring (CGM) reduce caregiver burden.
2. Medical Management: Lifelong medications, such as diazoxide and somatostatin analogs, pose challenges due to side effects and administration burden. Long-acting therapies like lanreotide lower treatment frequency, while caregiver training in device management enhances outcomes.
3. Cognitive and Physical Impact: Recurrent hypoglycemia can cause developmental delays and poor school performance. Early physical and cognitive therapies, coupled with school accommodations, improve outcomes.
4. Social and Psychological Impact: Social isolation and emotional stress affect both children and caregivers. Inclusive activities and counseling alleviate these challenges.
5. Caregiver Burden: Constant vigilance and financial strain create stress. Respite care and financial support programs help alleviate these pressures.
6. Therapeutic Advancements: PET/CT imaging distinguishes between focal and diffuse CHI, enabling tailored interventions. Long-acting therapies improve QoL by reducing treatment burden. Advocacy and standardized care protocols support families globally.
Conclusions
Effective CHI management requires addressing daily challenges to improve patient and caregiver QoL. Advances in therapies, genetic testing, and imaging have significantly mitigated these challenges, though financial and logistical barriers remain. Further research should explore long-term impacts of personalized therapies and global access to advanced care.
Keywords
Congenital hyperinsulinism, quality of life, dietary management, somatostatin analogs, caregiver burden, PET/CT imaging, advocacy programs.
Conclusions
CHI management requires a multidisciplinary approach addressing medical, dietary, psychological, and social challenges. Personalized interventions, advanced technologies, caregiver support, and long-term care strategies are crucial to improving outcomes and quality of life for affected families.

Neonatal hypocalcemic seizures revealing asymptomatic maternal hyperparathyroidism: case report and literature revue

Jaweher Kechiche[1], Abir Meherzi[1], Taieb Ach[2], Mouna Bellakhdher[1], GhadaSaad[2], Jihen Houas[1], Wassin Kermani[1], Yosra Hasni El Abed[2] & Mohamed Abdelkefi[1]
[1]Farhat Hached University Hospital, ENT Head and Neck Surgery, Sousse, Tunisia; [2]Farhat Hached University Hospital, Endocrinology Departement, Sousse, Tunisia

Introduction
Primary hyperparathyroidism during pregnancy is a rare condition increasing both maternal and perinatal morbidity and mortality. Thus, early detection and prompt surgery are essential, with the optimal timing being during the second trimester, which is considered safe. Maternal hyperparathyroidism can cause severe neonatal hypocalcemia and hypocalcemic tetany, affecting approximately 50% of infants born to mothers with untreated disease. Neonatal hypocalcemia results from prolonged parathyroid suppression due to chronic maternal hypercalcemia and the sudden cessation of maternal calcium transfer after delivery. The aim of this study is to highlight the importance of early diagnosis and management of maternal primary hyperparathyroidism during pregnancy to prevent neonatal complications, particularly hypocalcemic seizures.
Materials and methods
We present a case of recurrent neonatal tonico-clonic seizures due to undiagnosed asymptomatic maternal hyperparathyroidism.
Results
A fifteen-day-old male infant was presented to pediatric emergency department because of recurrent tonico-clonic seizures. Physical examination was normal. Ca level was 1.5 mmol/l, PTH levels was relatively low: 16 pg/mL. Transient hypoparathyroidism was considered as the cause of hypocalcemic seizures. The patient's mother had no complaints, nor a medical history. Her physical examination was normal. Biochemical evaluation revealed a serum total Ca level of 3,05 mmol/l. Serum phosphate level was 0,38 mmol/l. Urinary Ca was also elevated to 705 mg/24H. The PTH level was found to be 603 pg/mL while 25(OH) D level was low: 25 ng/mL. Parathyroid SPECT was performed with 99m Technetium-MIBI revealing a right inferior parathyroid adenom. Asymptomatic primary hyperparathyroidism was diagnosed and surgery was planned.
Conclusions
Unrecognized maternal hyperparathyroidism can suppresses fetal parathyroid activity and impairs the parathyroid response to hypocalcemia after birth. Based on our review of the literature, surgery is the preferred definitive treatment and is deemed safe and effective when performed during the second trimester of pregnancy.

Novel mutation in TBX1 in a neonate with hypocalcemic seizures and digeorge syndrome

Ivona Butorac Ahel[1], Jelena Radic Nisevic[2], Franka Kovacevic[2], Srecko Severinski[2] & Igor Prpic[2]
[1]Clinical Hospital Center Rijeka, Department of Pediatric endocrinology, Rijeka, Croatia; [2]Clinical Hospital Center Rijeka, Department of Pediatric Neurology, Rijeka, Croatia

Background
The 22q11.2 region covers approximately 30 genes, including TBX1, the mutation of which has been show to cause the 22q11.2 deletion syndrome. We report the case of a neonate with a novel heterozygous TBX1 mutation who experienced hypocalcemic seizures.
Case report
A 9-day-old female newborn was admitted to the pediatric neurological department to investigate recurrent focal tonic-clonic seizures. On admission, the physical examination was normal. The video-electroencephalography (EEG) was performed and ictal recording showed focal tonic and clonic seizures with bilateral propagation. Routine blood tests revealed hypocalcemia, total serum calcium of 1.66 mmol/l (2.15–2.8 mmol/l); and hyperphosphatemia, 3.42 mmol/l (1.25–2.5/mmol/l) with normal liver and kidney function, normal vitamin D level and negative inflammation markers. The parathyroid hormone levels were low on two occasions, 0.7 pg/ml and 0.3 pg/ml (1.3–9.3 pg/ml), respectively. The treatment consisted of controlling the seizures and correcting the hypocalcemia. A loading dose of phenobarbital (20 mg/kg) was administered, followed by oral administration. Since the seizures persisted, levetiracetam was added which led to seizure remission. The antiepileptic treatment with phenobarbital decreased serum calcium levels despite the simultaneous administration of calcium supplements. Calcium supplementation was started intravenously and, continued via the oral route. Hypoparathyroidism was transient and the treatment of hypocalcemia was stopped at the age of 2 months. Considering the association of neonatal hypocalcemia with hypoparathyroidism and seizures, DiGeorge Syndrome as well as other genetic disorders were taken into account. FISH did not reveal a 22q11.2 microdeletion. Further genetic analysis showed a novel T box-1 (TBX1) heterozygous mutation (c.337C>T; p.Gln113*). Over the next 4-month follow-up period the infant developed normally, without any seizures. EEG normalized and antiepileptic therapy was gradually discontinued.
Conclusion
A novel heterozygous TBX1 mutation was identified as a cause of neonatal hypocalcemic seizures and DiGeorge syndrome. We emphasize the importance of further genetic evaluation in infants with hypoparathyroidism without 22q11.2 deletion for detecting TBX1 mutations.

Necrolytic migratory erythema following prolonged continuous subcutaneous Dasiglucagon administration: a case report

Lucas Weschle[1], Jenny Potratz[1], Frank Rutsch[1], Alexander Humberg[1], Sandra Oesingmann[1], Andreas Pascher[1], Alexander S. Busch[1] & Katja Masjosthusmann[1]
[1]University Hospital Münster, Deptartment of General Pediatrics, Münster, Germany

Backrgound
Congenital hyperinsulinism (CHI) is a rare but severe disorder characterized by persistent hypoglycemia due to unregulated insulin secretion. Dasiglucagon, a synthetic glucagon analogue, has emerged as a promising treatment for CHI due to its stability and ease of use in continuous subcutaneous infusion. However, long-term safety data remain limited. Here, we describe a case of necrolytic migratory erythema (NME), a rare and severe dermatologic condition, associated with prolonged continuous subcutaneous dasiglucagon therapy.
Case
A male infant with CHI caused by compound-heterozygous mutations in *ABCC8* was treated with continuous subcutaneous dasiglucagon after standard therapies, including intravenous glucose, diazoxide, and octreotide, failed to achieve glycemic control. Initial dasiglucagon therapy with 20–60 µg/h was effective; however, after several weeks of treatment, the patient progressively developed erythematous, scaly skin lesions. This condition was accompanied by significant malnutrition, evidenced by a consistent downward trajectory across multiple weight percentile lines in serial measurements, along with zinc deficiency and hypoaminoacidemia. Based on the patient's history and clinical presentation, we strongly suspected necrolytic migratory erythema (NME). Given the patient's severe skin condition a central line was chosen to ensure secure intravenous access and targeted intravenous substitution of zinc, trace elements, amino acids, and fatty acids was initiated to treat malnutrition. While we initiated further diagnostic workup for NME, the patient developed Staphylococcus aureus-associated central line sepsis. Consequently, continuous subcutaneous dasiglucagon administration was tapered and the therapy was discontinued after a total of five months. The patient underwent subtotal pancreatectomy to manage persistent hypoglycemia. Postoperatively, his condition improved significantly, with resolution of the skin lesions and normalization of nutritional parameters through targeted supplementation. As expected, diabetes mellitus developed, requiring insulin therapy.
Discussion
Dasiglucagon has shown significant promise in managing severe hypoglycemia, owing to its rapid glucose-raising effects. While short-term use has demonstrated efficacy and tolerability across various therapeutic indications, our case of prolonged continuous use in CHI, which was complicated by the development of NME, underscores the critical importance of rigorous monitoring during extended treatment. Monitoring should prioritize the early identification of potential adverse effects, including dermatological conditions, amino acid and zinc deficiencies, and alterations in weight trajectory. Although this case report does not establish a direct causal relationship between continuous dasiglucagon therapy and NME, it emphasizes the need for vigilant long-term use, multidisciplinary care, and further research to enhance the understanding of its safety profile and optimize therapeutic strategies.

Evaluation of a new guideline for the early detection and management of neonatal hypoglycaemia

Lisa Friesl[1], Marcia Roeper[1], Henrike Hoermann[1], Sebastian Kummer[1] & Thomas Meissner[1]
[1]University Hospital Düsseldorf, Department of General Pediatrics, Neonatology and Pediatric Cardiology, Düsseldorf, Germany

Introduction
Neonatal hypoglycaemia is the most common metabolic condition in neonates. It affects up to 15% of all neonates and 50% of neonates born with risk factors. However, there is still no international consensus on treatment thresholds and management strategies for neonatal hypoglycaemia. In March 2020, a new standard operating procedure (SOP) for the "early detection and treatment of neonatal hypoglycaemia" for newborns born after 35 weeks of gestation was introduced at the Paediatric and Obstetric Clinic of the University Hospital Düsseldorf. The development of this SOP was based on an extensive review of various international guidelines. The SOP provides a preventative approach for children with risk factors for neonatal hypoglycaemia and includes standardised blood glucose screening and treatment of hypoglycaemia if necessary. The aim of this study is to compare a retrospective (pre-SOP) and a prospective (post-SOP) cohort to investigate whether the SOP has improved the early detection and management of hypoglycaemia and whether the number of severe or prolonged hypoglycaemia has decreased. It will also compare the frequency of hypoglycaemia, the number of blood glucose measurements, the rate of transfer to the paediatric clinic, the duration of treatment with intravenous glucose, and the overall inpatient treatment.
Methods
The study includes a total of 607 children born at the University Children's Hospital Düsseldorf, 280 born before to the implementation of the new SOP (before March 2020) and 327 born after the implementation of the new SOP. The cohorts were matched for sex, birth weight, gestational age, and risk factor for neonatal hypoglycaemia.
Results
All patients have been enrolled in the study. Data collection is currently being completed. We then plan to perform statistical analyses and present the final data at the conference.
Conclusion
Given the high incidence of hypoglycaemia in neonates, it is of great interest to determine whether the new standard can detect hypoglycaemia more frequently, prevent profound hypoglycaemia, reduce the number of severe and prolonged hypoglycaemic episodes and thus prevent possible negative consequences due to brain damage. However, the 'costs' of interventions also need to be analysed, including patients who have received interventions but are unlikely to have benefited from them. It is only through such analyses that evidence-based guidelines can be developed, which is urgently needed for an issue as important as neonatal hypoglycaemia to improve the approach for future generations.

Cloudy blood, clear diagnosis: homozygous GP1HBP1 mutation in a 20 day old neonate

Bhanu Nalluri[1], Neelaveni K[1] & Rakesh Sahay[1]
[1]Osmania General Hospital, Departement of Endocrinology, Hyderabad, India

Background
Severe hypertriglyceridemia and dyslipidemia in infancy are rare, often presenting with nonspecific signs that complicate early diagnosis and management. Genetic causes, such as mutations in key triglyceride metabolism proteins, are frequently implicated. GP1HBP1 (Glycosylphosphatidylinositol-anchored high-density lipoprotein-binding protein 1) is critical for the interaction between lipoprotein lipase (LPL) and triglyceride-rich lipoproteins. Mutations in GP1HBP1 impair triglyceride clearance, leading to extreme hyperchylomicronemia, characterized by markedly elevated triglycerides, lipemia retinalis, and risk of acute pancreatitis[1]. Early recognition of genetic hyperlipidemias is crucial for prompt intervention and prevention of complications[2].
Case Presentation
We report a 20-day-old neonate presenting with fever and incidentally noted cloudy blood samples. Lipid profile showed extreme hyperlipidemia: total cholesterol 702 mg/dL, triglycerides 12,583 mg/dL, HDL 51 mg/dL, and VLDL 2,517 mg/dL. The infant, born full-term with no neonatal complications, had no xanthomas, xanthelasmas, or family history of dyslipidemia. Fundoscopy revealed lipemia retinalis; abdominal ultrasound was normal. Genetic testing identified a homozygous pathogenic GP1HBP1 variant, confirming autosomal recessive chylomicronemia syndrome[1]. Management included a low-fat maternal diet (as the infant was exclusively breastfed) and omega-3 fatty acid supplementation (2 g/day)[3].
Discussion
This case highlights the need to consider genetic dyslipidemias in neonates with severe hypertriglyceridemia. GP1HBP1 mutations disrupt LPL activity, causing impaired triglyceride metabolism[1]. Management focuses on dietary fat restriction, omega-3 supplementation, and close monitoring to prevent complications like pancreatitis and cardiovascular disease[2,3]. Early genetic diagnosis facilitates targeted management and family counseling.
Conclusion
This report underscores the importance of early recognition and a multidisciplinary approach in managing severe neonatal hyperlipidemia due to GP1HBP1 mutations, optimizing outcomes in rare genetic dyslipidemias.

Unraveling genotype-phenotype interactions in congenital hyperinsulinemic hypoglycemia: implications for targeted therapies and diazoxide responsiveness

Ashraf Soliman[1], Noora AlHumaidi[1], Noor Hamed[1], Shayma Ahmed[1], Nada Alaaraj[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Congenital Hyperinsulinemic Hypoglycemia (CHI) is a rare disorder of insulin dysregulation caused by genetic mutations that impair the function of pancreatic β-cells. Accurate genotype-phenotype correlations and understanding of therapeutic responses, including to diazoxide, are crucial for effective diagnosis and management. This review examines molecular findings, diazoxide response rates, and alternative therapies for CHI, focusing on phenotype and genotype relationships.
Methods
A systematic review of studies published from 2013 to 2025 was conducted, analyzing genetic variants, clinical phenotypes, and diazoxide response rates. Data were extracted from verified studies on key genotypes (e.g., ABCC8, KCNJ11, GLUD1, HNF4α, GCK, and INSR) and phenotypes (e.g., diffuse, focal, atypical, and transient CHI).
Results
Data from 546 patients across 14 studies revealed distinct patterns in diazoxide response by genotype and phenotype.
• Genotype-based responses:
• ABCC8 and KCNJ11 mutations, the most common genetic causes of CHI, showed low response rates to diazoxide (40% and 50%, respectively).
• GLUD1 mutations had high response rates (81%), while GCK mutations were moderately responsive (71%).
• HNF4α mutations exhibited the highest response rates (90%), whereas INSR mutations were poorly responsive (30%).
• Phenotype-based responses:
• Diffuse CHI, often associated with severe neonatal presentations, had a low response rate (35%).
• Focal CHI, typically caused by paternal ABCC8 mutations with somatic loss of heterozygosity, showed the highest response rate (90%) after surgical resection.
• Atypical CHI demonstrated variable diazoxide responsiveness (50%), reflecting its heterogeneous etiology.
• Transient CHI, common in mild and perinatal cases, had a high response rate (80%) with medical therapy.
• Therapeutic insights:
• Long-acting somatostatin analogs, such as octreotide and lanreotide, provided effective alternatives for diazoxide-unresponsive diffuse and atypical CHI cases.
• Emerging therapies, including GLP-1 receptor antagonists, showed promise in preclinical studies for severe CHI unresponsive to standard treatments.
Conclusions
The genotype and phenotype of CHI strongly influence therapeutic outcomes, particularly diazoxide responsiveness. Diffuse and severe forms often require alternative therapies or surgery, while milder forms respond well to medical management. Comprehensive molecular and phenotypic analysis is essential for tailoring treatment and improving long-term outcomes in CHI. Further research into personalized therapeutic approaches and emerging treatment options is warranted.
Keywords
Congenital hyperinsulinism, ABCC8, KCNJ11, diazoxide, somatostatin analogs, GLP-1 receptor antagonists, genotype-phenotype correlation.

JOINT953

"Genotype and phenotype-driven probability of therapeutic response in congenital hyperinsulinism"

Ashraf Soliman[1], Ahmed Elawwa[1], Nada Alaaraj[1], Noor Hamed[1], Shayma Ahmed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Congenital hyperinsulinism (CHI) is the most common cause of persistent hypoglycemia in neonates and infants, caused by dysregulated insulin secretion. The probability of response to diazoxide, first-line therapy, and other medical or surgical treatments varies based on genetic mutations and phenotypic presentations. Understanding these factors is crucial for optimizing treatment strategies.
Objective
To evaluate the probability of therapeutic response in CHI based on genetic mutations and phenotypic factors, highlighting genotype-phenotype correlations.
Methods
A literature review of studies between 2000 and 2024 was conducted, focusing on the influence of genetic mutations (ABCC8, KCNJ11, GLUD1, HNF4A, and HNF1A) and phenotypic factors (histological subtypes, age of onset) on diazoxide response and other treatment outcomes. Data were synthesized to calculate probabilities of therapeutic success.
Results
1. Genetic Factors and Diazoxide Response:
• KATP Channel Mutations (ABCC8, KCNJ11):
• Dominant mutations: High probability of diazoxide response (>70%), as partial loss of function allows diazoxide to activate the KATP channel.
• Recessive mutations: Low response probability (<30%), associated with severe diffuse CHI due to complete channel dysfunction.
• Other Mutations:
• GLUD1: Very high response probability (>80%) due to effective suppression of insulin secretion with diazoxide.
• HNF4A/HNF1A: High probability (>80%), associated with mild forms of CHI.
2. Phenotypic Factors:
• Histological Subtype:
• Focal CHI: Response probability depends on mutation; lesions are often curable with lesionectomy.
• Diffuse CHI: Low diazoxide response probability (<20%); near-total pancreatectomy often required.
• Age of Onset:
• Neonatal CHI: Severe phenotype with low diazoxide response.
• Later-Onset CHI: Milder phenotype with higher diazoxide responsiveness.
3. Alternative Therapies:
• For diazoxide-unresponsive cases, therapies such as octreotide, lanreotide, and CGM-assisted glucose monitoring are effective, particularly in severe or diffuse CHI.
Conclusions
The probability of therapeutic response in CHI is highly dependent on genotype and phenotype. Diazoxide is effective in patients with dominant KATP mutations, GLUD1, and HNF4A mutations, while recessive KATP mutations and diffuse CHI predict poor response. Individualized treatment strategies based on genetic and phenotypic profiling are essential to optimize outcomes in CHI patients.

JOINT3718

The role of surgery in the 3rd trimester in the management of hypercalcaemia in pregnancy

Hafsah Hussain[1], Furhana Hussein[1], Chineze Otigbah[1], Lina Eltayieb[1], Bashir Mahamud[1], Lubna Etbinah[1] & Gideon Mlawa[1]
[1]Barking, Havering, and Redbridge University Hospitals NHS Trust, Romford, United Kingdom, London, United Kingdom

Introduction
Hypercalcemia during pregnancy, while uncommon, is not exceedingly rare. The management of hypercalcemia in pregnancy can be particularly challenging with the approach largely depending on the trimester in which the condition is diagnosed. Treatment strategies include conservative management, medical therapy, or, in some cases, surgical intervention.
Case
A 30-year-old woman was reviewed in the antenatal clinic at 12 weeks of gestation, with blood tests revealing hypercalcemia. Her calcium level was 2.89 mmol/l, parathyroid hormone (PTH) level was elevated at 8.24 pg/ml, urinary calcium was 9.1 mg/24h, and vitamin D level was 58 nmol/L. She was asymptomatic at the time. An ultrasound of the parathyroid glands revealed a left superior parathyroid adenoma. She was referred to the surgical team for consideration of surgery. While awaiting surgical intervention, she was advised to increase her oral fluid intake. Due to delays in the surgical consultation during the second trimester, she was initiated on Cinacalcet therapy. However, she later developed polyhydramnios, prompting an urgent and successful parathyroidectomy at 30 weeks of gestation. Following the surgery, her calcium level normalized to 2.33 mmol/l. She subsequently delivered a healthy baby without complications.
Discussion
Hypercalcemia can be caused by a variety of conditions including primary hyperparathyroidism, malignancy, sarcoidosis, and certain medications. In pregnancy, primary hyperparathyroidism is the most common cause, and the management of hypercalcemia is contingent upon the trimester in which the diagnosis is made. Treatment options may include conservative measures such as intravenous fluids, medical therapies like Calcitonin or Cinacalcet, and surgical intervention. Surgical treatment is generally recommended in the second trimester to prevent both maternal and foetal complications. In cases of symptomatic

hypercalcemia, surgical intervention may be indicated later than the 2nd trimester as seen in this case.
Conclusion
Surgical intervention for hypercalcemia during pregnancy is typically recommended in the second trimester. However, surgery may be necessary in the third trimester, particularly in cases of symptomatic hypercalcemia. In this case, the patient developed polyhydramnios, likely secondary to hypercalcemia, and parathyroidectomy was performed at 30 weeks of gestation which helped manage symptoms and prevented further foetal complications and resulted in an uncomplicated delivery of baby.

Clinical experience with various persistent congenital hyperinsulinisms in a single tertiary care center: a case series

Goo Lyeon Kim[1] & Jeesuk Yu[1]
[1]Dankook University Hospital, Pediatrics, Cheonan, South Korea

Introduction
Congenital hyperinsulinism (CHI) is a disease group characterized by inappropriate insulin secretion leading to hypoglycemia. Genetic testing helps diagnose diseases, select effective treatments, and provide genetic counseling for families. Disease-causing single nucleotide variants affecting more than 30 genes are reported to cause persistent hyperinsulinism. F-DOPA PET CT imaging is also used to identify patients who may require surgical treatment. Medical treatment of hyperinsulinism includes medications such as diazoxide, somatostatin analogues, calcium channel blockers, and glucagon. We would like to review six cases experienced in our hospital and share information on appropriate treatment for this condition.
Cases
There were 6 patients with persistent congenital hyperinsulinism, 3 were diagnosed with hyperinsulinemia in the neonatal period due to hypoglycemia that occurred on the day of birth, and 3 were diagnosed with congenital hyperinsulinism after visiting the hospital due to convulsions and hypoglycemia after infancy. All 6 patients started treatment with diazoxide, and 4 patients continued treatment with diazoxide, but 1 patient developed significant pulmonary hypertension while taking diazoxide and was changed to octreotide, and the remaining 1 patient changed to octreotide because his blood sugar was not sufficiently controlled with diazoxide, but could be changed back to diazoxide at 3 years of age and continued to take diazoxide until the age of 8. In the genetic panel test, no mutations were found in 2 patients, and ABCC8 gene mutations were found in 3 patients. One patient with an ABCC8 mutation stopped taking diazoxide at age 8, was diagnosed with diabetes mellitus at age 13, and is currently taking oral hypoglycemic agents. F-dopa PET-CT was performed to two patients in whom no genetic mutation was detected, and both were confirmed to have diffuse type of CHI.
Conclusions
Diazoxide is an approved oral drug for the treatment of hyperinsulinism, despite the possibility of rare but serious side effects such as pulmonary edema or hypertension. Serious side effects including pulmonary hypertension should be kept in mind when administered to neonates. The clinical manifestations of permanent congenital hyperinsulinism are diverse, so careful attention is needed to ensure appropriate treatment.

JOINT803

Comparative outcomes of medical and surgical management in children with persistent neonatal hyperinsulinemic hypoglycemia: a focus on long-term growth, metabolic, and developmental implications"

Ashraf Soliman[1], Muna Sharaf[2], Fawzia Alyafei[1], Shayma Ahmed[1], Noor Hamed[1] & Nada Alaaraj[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Ibn Sina Hospital, West Bank, Palestine

Background
Congenital hyperinsulinism (CHI) is the most common cause of persistent hypoglycemia in neonates and infants, posing significant challenges in management. Hypoglycemia during the neonatal period is particularly difficult to control due to the severity and variability of the disease. While medical treatments such as diazoxide or octreotide are often first-line, they fail in severe or diazoxide-unresponsive cases, necessitating surgical intervention, such as partial or near-total pancreatectomy. Long-term outcomes of these treatments vary significantly, impacting growth, metabolic control, and neurodevelopment.
Objective
To compare the outcomes of medical vs surgical treatments in managing persistent neonatal hypoglycemia caused by CHI, focusing on growth, metabolic, and developmental outcomes.
Methods
This review consolidates data from 20 studies published between 1990 and 2023, involving over 2,000 patients with CHI. Studies were evaluated based on treatment modalities (medical or surgical), long-term outcomes related to growth, metabolic health, and neurodevelopment, and genetic correlations.
Results
• Growth Outcomes: Patients on medical therapy generally demonstrated normal growth trajectories, provided hypoglycemia was well-controlled. Surgical interventions, particularly near-total pancreatectomy, resulted in significant growth impairments in some studies. For instance, Soliman *et al*. (1998) reported height scores of -2.57 SD, reflecting growth retardation, while most patients in Beltrand *et al*. (2012) maintained normal growth.
• Metabolic Outcomes: Medical therapy successfully managed hypoglycemia in approximately 50-71% of patients, with diazoxide efficacy varying based on genetic mutations. Surgical treatments resolved hypoglycemia in 97% of focal CHI cases but were less effective in diffuse CHI, with 50% experiencing persistent hypoglycemia post-surgery. However, near-total pancreatectomy carried a high risk of insulin-dependent diabetes (40-96%) and exocrine insufficiency.
• Developmental Outcomes: Neurodevelopmental delays were observed in both groups, particularly in patients with prolonged or inadequately controlled hypoglycemia. Surgical patients exhibited higher rates of neurobehavioral deficits (up to 55% in Rasmussen *et al*., 2020), while early and effective medical management mitigated these risks in many cases.
Conclusion
Management of CHI remains challenging, with both medical and surgical treatments presenting unique benefits and risks. Medical therapy is effective for many cases but is limited in severe, diazoxide-unresponsive CHI. Surgical intervention, while curative in focal disease, is associated with long-term complications, including diabetes and neurodevelopmental delays. Early diagnosis, individualized treatment plans, and multidisciplinary care are essential to optimize outcomes. Future advancements in genetic analysis and novel therapies are urgently needed to improve the prognosis for these patients.

Hypoglycemia screening before discharge in newborn identified as at risk

Kansuda Ariyawatkul[1], Kanokwan Aeimcharnbanchong[1], Rinrada Piyawannkul[1] & Jiratt Kongchalard[1]
[1]Panyananthaphikkhu Chonprathan Medical Center, Srinakharinwirot university, Nonthaburi, Thailand

Neonatal hypoglycemia is a common metabolic disturbance that can adversely affect neurological development. Current guidelines focus on screening and managing hypoglycemia in the first 24 h of life, yet some asymptomatic at-risk infants experience hypoglycemia between 24 to 48 h, with limited recommendations for this critical period. This study aims to assess glucose screening at 48 h of age to ensure safe discharge for asymptomatic neonates at risk of hypoglycemia. A prospective cohort study was conducted from July 2023 to May 2024 at a tertiary care hospital. Asymptomatic neonates aged 48-60 h with gestational ages between 34-41 weeks, identified as at risk for hypoglycemia, were enrolled. Blood glucose levels were measured using both a glucometer and standard plasma glucose testing. Among the 139 newborns included in the study, the incidence of hypoglycemia varied significantly between glucometer (10.8%)

Table 1. Laboratory values of cases

Factors	Unadjusted odds ratio (95%confidence interval)	Adjusted OR (95%CI)
Type of feeding before discharge		
Breastfeeding	Reference	Reference
Infant Formula	0.22 (0.04, 1.2)	0.17 (0.03, 1)
Breastfeeding and Infant Formula	1.30 (0.54, 3.13)	1.27 (0.52, 3.12)
Discharge weight		
> 2,500 gm	Reference	Reference
≤ 2,500 gm	2.22 (1.03, 4.78)	2.46 (1.09, 5.57)

and standard plasma glucose (48.9%) measurements. Infants with discharge weights below 2500 grams were twice as likely to experience hypoglycemia (OR: 2.221, $P = 0.042$). Despite a strong correlation ($r=0.725$,$P < 0.001$) between glucometer and plasma glucose readings, glucometers tended to overestimate glucose levels, particularly at lower glucose concentrations.

Conclusion

There is a high incidence of hypoglycemia among asymptomatic neonates identified as at risk before discharge. Asymptomatic neonates with risk factors for hypoglycemia who have a discharge weight of $\leq$ 2,500 grams should be screened for hypoglycemia at 48 to 60 h of age to ensure their safe discharge from the hospital.

JOINT2836

New insights into hypothalamic dysfunction: schaaf-yang syndrome in two infants

Barbora Obermannova[1], Barbora Jírová[2], Aneta Kodytková[2] & Miroslava Balscakova[3]

[1]Department of Paediatrics, 2nd Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic; [2]2nd Faculty of Medicine, Charles University and University Hospital Motol, Department of Paediatrics, Prague, Czech Republic; [3]2nd Faculty of Medicine, Charles University and University Hospital Motol, Institute of Biology and Medical Genetics, Prague, Czech Republic

Objective

To delineate the chronological progression and pathophysiological effects of *MAGEL2* mutations in infants with Schaaf-Yang syndrome, focusing on associated endocrine disorders and developmental dysfunctions such and characteristic dysmorphisms.

Methods

A detailed review of clinical, hormonal, and genetic data from two infants with Schaaf-Yang syndrome, including the onset of specific endocrine characteritics and developmental features, particularly those related to *MAGEL2* mutations.

Results

AVP-D Both infants presented with symptoms of arginine vasopressin deficiency (AVP-D) such as hypernatremia and polyuria from the neonatal period, highlighting disturbances in hypothalamic function. **Hypopituitarism:** Manifestations of growth hormone deficiency and transient adrenal insufficiency were noted early in life, typically emerging within the first few months. **Delayed Hyperinsulinism:** Diagnosis of hyperinsulinism occurred at seven and eleven months, managed with diazoxide and octreotide, reflecting progressive pancreatic beta-celldysfunction. **Genetic Insights:** Infants displayed *de novo* truncatingmutations in the *MAGEL2* gene (c.1996dup and c.1912C>T), which correlate with more severe phenotypic manifestations. **Developmental Dysmorphisms:** Both infants exhibited characteristic facial features (broad forehead, almond-shaped eyes, flattened nasal bridge, thin upper lip) and finger contractures associated with oligohydramnios, highlighting the prenatal impact of *MAGEL2* mutations.

Conclusion

The profound endocrine and developmental manifestations in Schaaf-Yang syndrome underscore the criticalrole of *MAGEL2* mutations in disrupting hypothalamic functions. These mutations not only impair hormone regulation leading to AVP-D, hypopitutarism and hyperinsulinism but also affect prenatal development, contributing to distinct facial dysmorphisms and contractures. This detailed understanding is crucial for developing targeted interventions and managing the complex endocrine dysfunctions in SYS, facilitating improved outcomes through proactive and informed therapeutic strategies.

JOINT3337

A case of PURA syndrome characterized mainly by hypotonia and hypersomnia

Ping Li[1] & Jie Xing[1]

[1]the Second Hospital of Jilin University, Department of Developmental Pediatrics, Changchun, China

Background

PURA syndrome (OMIM: 616158) is a neurodevelopmental disorder caused by heterozygous pathogenic variants in the PURA gene (5q31.3), which encodes a DNA/RNA-binding protein critical for neuronal myelination, synaptic plasticity, and cell cycle regulation. Characterized by neonatal hypotonia, feeding difficulties, hypersomnolence, and global developmental delay, this syndrome needs to be clinically differentiated from diseases such as Prader-Willi syndrome with hypotonia and developmental delay.

Clinical Case

An 8-month-old male presented with profound axial hypotonia (inability to lift head or roll over), hypersomnolence (18 hour/day), and delayed motor milestones. Neonatal history included respiratory distress syndrome, intraventricular hemorrhage (Grade II), and periventricular leukomalacia. Neurological examination revealed normocephalic head, intact visual tracking, absent auditory orientation, and preserved tendon reflexes. Serial evaluations excluded metabolic disorders (normal tandem mass spectrometry), cardiac defects (unremarkable echocardiography), and negative 15q11 methylation analysis. Trio whole-exome sequencing identified a de novo heterozygous PURA frameshift variant (NM_005859.5:c.523del, p.Asn175Thrfs50) in exon 1, classified as pathogenic (PVS1, PS2, PM2). At 3-year follow-up, the patient exhibited severe motor delay (non-ambulatory, absent sitting balance), growth restriction (<3rd percentile), and language impairment (no meaningful words). Neuroimaging showed persistent white matter hyperintensities. Management included enteral nutrition support, vitamin D supplementation, and intensive neurorehabilitation. This report delineates the natural history and molecular confirmation of a novel PURA frameshift variant.

Conclusion

This case reinforces the core phenotype of PURA syndrome: neonatal-onset hypotonia, hypersomnolence, and irreversible neurodevelopmental deficits. The identified exon 1 truncating variant likely disrupts PUR-alpha's N-terminal domain, impairing its role in mRNA transport and translation. Given the lack of disease-modifying therapies, we advocate standardized surveillance protocols encompassing EEG (for seizure risk), spine imaging (scoliosis progression), and swallow studies. This study delineates the clinical and molecular characteristics of a novel PURA-associated syndrome. The variant (NM_005859.5:c.523del, p.Asn175Thrfs50) expands the mutational spectrum, correlating with extreme hypersomnolence severity.

[1]Copenhagen University Hospital - Rigshospitalet, The Fertility Clinic, Department of Gynaecology, Fertility and Obstetrics, Copenhagen, Denmark; [2]Copenhagen University Hospital - Herlev Hospital, Department of Paediatrics and Adolescent Medicine, Copenhagen, Denmark; [3]Copenhagen University Hospital - Rigshospitalet, The Obstetrics Clinic, Department of Gynaecology, Fertility and Obstetrics, Copenhagen, Denmark; [4]Copenhagen University Hospital - Rigshospitalet, The Fetal Medicine Unit, Department of Gynaecology, Fertility and Obstetrics, Copenhagen, Denmark; [5]Copenhagen University Hospital - Rigshospitalet Glostrup, Department of Clinical Biochemistry, Copenhagen, Denmark; [6]University of Copenhagen, Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen, Denmark; [7]University of Copenhagen, Department of Cellular and Molecular Medicine, Copenhagen, Denmark; [8]University of Copenhagen, Section of Biostatistics, Department of Public Health, Copenhagen, Denmark

Background

The increasing rate of infertility drives rapid advancements in assisted reproductive technology (ART). Improved cryopreservation techniques have significantly increased the use of embryos that have been frozen/thawed (frozen embryo transfer; FET) in ART. FET offers benefits over conventional fresh embryo transfer (fresh-ET) by reducing some pregnancy complications associated with fresh-ET. However, F*et al*so carries increased obstetric and perinatal risks, such as preeclampsia, increased birthweight and increased risk of being born large for gestational age (LGA). Both preeclampsia and LGA is known to predispose children to obesity and later cardiometabolic diseases.

Aim

The study aims to uncover the mechanism underlying the altered obstetric outcomes and fetal growth following FET and to determine the health implications for the children. The study hypothesizes that the freezing/thawing induces epigenetic changes in the embryo causing fetal and placental overgrowth. This leads to preeclampsia and LGA and potentially impacts cardiometabolic health in the children.

Methods

The prospective cohort will include 600 pregnant women, partners and offspring, equally comprised of pregnancies achieved after ART with FET, ART with fresh-

ET and naturally conceived (NC) pregnancies. The study includes extensive data collection from medical records, questionnaires, laboratory tests and clinical examinations. The pregnant women undergo three examinations during pregnancy to assess biomarkers of preeclampsia and maternal metabolism and growth factors. Fetal growth is determined by serial ultrasound scans. Epigenetic and transcriptomic profiles in placenta and cord blood is investigated upon delivery. The children are examined at three months of age with evaluation of body composition by an air displacement plethysmography scan and a dual-energy X-ray absorptiometry scan. Cardiometabolic biomarkers and hormones of minipuberty are analyzed in blood samples. To determine the genetic contribution to phenotypic traits, single-nuclei-polymorphism genotyping is performed and a polygenic score for major cardiometabolic traits calculated. The study commenced May 2024, currently 201 participants are enrolled and 25 children born.

Outcomes and scientific impact

The study is powered to detect a difference in birthweight (SDS) between FET, Fresh-ET and NC. Secondary outcomes are grouped into work packages and compared between the groups. WP2 (pregnancy): incidence of preeclampsia, WP3 (placenta): placental weight, WP4 (child): fat percentage, WP5 (epigenetics): DNA methylation in cord blood and placenta, WP6 (genetics): deviation from genetically determined birthweight. Several exploratory outcomes are defined. We expect our study to identify key mechanisms related to outcomes after FET that could inform clinical practices and improve long-term health for mothers and children conceived after ART.

Update on the association of prenatal and postnatal exposures to acetaminophen and neurodevelopmental disorders

Rebeca Mira Sánchez[1] & Hassan Heshmati[2]

[1]Instituto de Ciencias Medioambientales y Neurodesarrollo ICMYN, University of Murcia, Murcia, Spain; [2]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, United States

Introduction

Acetaminophen (paracetamol) is traditionally considered a safe medication for the management of fever and pain in pregnant women and in children. Although several studies have reported that postnatal exposure to acetaminophen in susceptible children is associated with neurodevelopmental disorders, data on its neurodevelopmental impact after prenatal exposure are controversial. This review presents an update on the association of prenatal and postnatal exposures to acetaminophen and neurodevelopmental disorders.

Methods

A systematic search of literature was conducted using the search terms acetaminophen, endocrine-disrupting chemicals, prenatal exposure, postnatal exposure, and neurodevelopmental disorders.

Results

Acetaminophen, a widely used over-the-counter medication, is a non-opioid antipyretic and analgesic drug. It is used by more than 50% of pregnant women for the treatment of fever and pain. Neurodevelopmental disorders can affect all types of populations and cause high cost to the economy. Although some studies have suggested that prenatal exposure to acetaminophen is associated with high incidence of neurodevelopmental disorders in the offspring (e.g., autism spectrum disorder and attention-deficit/hyperactivity disorder), a sibling control analysis of a large population of children exposed to acetaminophen through pregnancy ($n = 185{,}909$) showed that there is no significantly increased risk of autism, attention-deficit/hyperactivity disorder, and intellectual disability in children exposed prenatally. In contrast, most studies of postnatal exposure to acetaminophen have reported that the use of acetaminophen in susceptible infants and children is associated with multiple neurodevelopmental disorders. Acetaminophen intake during pregnancy has also been reported in association with increased male reproductive and urogenital disorders (e.g., cryptorchidism and hypospadias) likely due to the endocrine-disrupting properties of the medication. These findings have important implications for the management of fever and pain in pregnant women and in children. Because of the economic and psychological burden of neurodevelopmental disorders, it is urgent to conduct more high-quality studies with adequate control to assess the association of prenatal use of acetaminophen and neurodevelopmental disorders before proposing clinical guidelines. However, until proven otherwise, pregnant women should have limited use of acetaminophen (e.g., lowest effective dose for the shortest possible time).

Conclusion

It is well established that the postnatal exposure to acetaminophen can increase the risk of neurodevelopmental disorders in children. However, the neurodevelopmental consequences of prenatal exposure to acetaminophen are not clearly established and require further investigations. Until proven otherwise, it is recommended that the intake of acetaminophen during pregnancy be reduced as much as possible.

The neonatal TSH screening as an indicator of the iodine status in newborns in bulgaria: actual data 2021-2024

Iva Stoeva[1,2], Iskra Modeva[3,4], Violeta Kozhuharova[3], Zoia Todorova[3] & Tsvetoslav Petrov[1]

[1]USPHAT "Prof. Ivan Mitev", Sofia, Bulgaria; [2]State University "Prof. Assen Zlatarov", Medical Faculty, Burgas, Bulgaria; [3]USPHAT "Professor Ivan Mitev", Screening and Functional Endocrine Diagnostics, Sofia, Bulgaria; [4]Medical University, Medical Faculty, Sofia, Bulgaria

Current WHO guidelines consider that under an adequate iodine intake $< 3\%$ of the newborns (NB) should have TSH levels of > 5 mU/l at screening. The neonatal TSH screening was implemented in 1993. A new National Program focused on sustainable elimination of iodine deficiency disorders took place in 1994 and universal salt iodization for the whole country became mandatory. According to ICCIDD criteria Bulgaria was declared as "Iodine sufficient" in 2007.

Aim

To analyze the age-adjusted TSH distribution and provide actual data connected to the iodine intake in NB's between 2021-2024.

Material&Methods

Data from 177 607 NB (84.37% of all screened NB) aged 3rd-5th day of life were analyzed by TSH (DELFIA^{R} Perkin Elmer) in dried blood spots from 28 Bulgarian districts (107 maternities) between 2021-2024. Results: compared to 2006/2007 (2.8% of NB $>$ 5 mU/l) the proportion of NB with TSH $>$ 5 mU/l increased to 6.18% between 2021-2024 for the entire country. According to the TSH cut off 5 mU/l only one district was completely iodine sufficient during the entire period. Other districts showed fluctuations between sufficiency and mild iodine deficiency. Therefore the neonatal TSH distribution corresponds to mild iodine deficiency.

Conclusions

The neonatal TSH monitor was implemented as a constant part of the complex iodine monitoring program early at national, regional and hospital level. Despite a lot of factors influencing the TSH distribution, targeted actions are now necessary in order to proof and further evaluate the alarming situation of mild iodine deficiency appearing again in the country in the NB's as the most sensitive and vulnerable population for development of mental deficits.

JOINT1076

A rare case of a male infant in mini-puberty presenting with premature pubarche and non-classical congenital adrenal hyperplasia

Zheng Shaoping[1] & Ma Huamei[1]

[1]the First Affiliated Hospital-Sun Yat-sen University, Guangzhou, China

Background

Nontumorous premature pubarche is rare in infants, as the physiological variations in the gonadal and adrenal axes during mini-puberty make etiological diagnosis challenging.

Purpose

To report a case of self-limited premature pubarche in a 5^{+}-mo-old male infant with nonclassical congenital adrenal hyperplasia (NCCAH).

Methods

Case study.

Results

A 5^{+}-mo-old male infant was referred to our clinic due to be found with the presence of pubic hair for 8 days. Being the second child of non-consanguineous

Chinese parents, he was born by cesarean section due to premature rupture of membranes in pre-term with appropriate weight and length in good condition (36^{+5} weeks, 2500g,48cm). At 3-mo-old, he was diagnosed with"eczema"and administered with topical glucocorticoids intermittently for 2^{+} months until now. At 4-mo-old, serum 17OHP was tested to be 2.63 ng/ml due to vomiting. Physical examination revealed thick and long pubic hair on the mons pubis-without hyperpigmentation or enlargement of the penis. His height (–0.04 SDS) and weight (-0.9 SDS) were normal for his age. Laboratory test: E_2 21 pg/ml, T 0.67 ng/ml, P 0.20 ng/ml, DHEAs 3.34μmol/L, cortisol 8.6μg/dl, ACTH 10.2 pmol/L, androstenedione(A^4) $<$1.05 nmol/L. Serum β-hCG, AFP and CEA were normal. At 7^{+}-mo-old(one month after topical steroid withdrawal), the patient was admitted to the hospital due to slightly aggravated pubic hair development. Physical examination revealed scattered large patches of papular rash on the trunk, one acne on the face, and 4 ml testis. GnRHa (triptorelin) 60-minute stimulation test: FSH 1.05→3.02 IU/L, LH 1.13→11.39 IU/L; 8-hour ACTH stimulation test: 17OHP 2.01→18.03 ng/ml, cortisol 5.8→48.8μg/dl, P 0.30→1.8 ng/ml, E_2 12→51 pg/ml, T 0.38→0.13 ng/ml, A^4 $<$1.05→1.29 nmol/L, $DHEA_S$ 1.57→1.92μmol/L. Bone age was 9 months. Testicular ultrasound, adrenal CT, pituitary MRI did not show any abnormalities. Due to his elevated base and ACTH-stimulated serum 17OHP concentration, Whole exome sequencing and *CYP21A2* gene analysis (Sanger sequencing and MLPA) were performed and revealed negative result. At 3y3m, the boy's pubarche spontaneously resolved at age 10^{+}-mo-old after a slightly increase and darkening for one more month, with no other signs of virilization, and growth velocity remained normal.

Conclusions

We report a rare self-limited premature pubarche case of a male infant in mini-puberty with biochemical NCCAH. The premature pubarche is not related to NCCAH.

Key words

Mini-puberty, non-classical congenital adrenal hyperplasia, premature pubarche.

A macrosomic preterm baby with hypoinsulinemic hypoketotic hypoglycemia: a diagnostic puzzle

Gizem Boke Kocer[1], Sibel Tugce Aygun[1], Selen Hürmüzlü Közler[1], Esra Kocyigit[1], Huseyin Demirbilek[2], Sarah Flanagan[3], Jeremy Huw Jones[1] & Filiz Mine Cizmecioglu-Jones[1]

[1]Kocaeli University Faculty of Medicine, Department of Child Health, Pediatric Endocrinology & Diabetes, Kocaeli, Türkiye; [2]Hacettepe University Faculty of Medicine, Ankara, Türkiye; [3]University of Exeter Medical School, Exeter, United Kingdom

Introduction

In cases of hypoketotic hypoglycemia mimicking hyperinsulinism, pathogenic variants in post-receptor signaling cascades lead to autonomous activation of insulin signaling in target tissues, causing severe hypoglycemia with low or undetectable insulin. This report highlights the challenges in diagnosis and management of hypoinsulinemic hypoketotic hypoglycemia (HHH) and discusses available treatment options.

Case Report

A male neonate was born at 33 weeks gestation to non-consanguineous parents, with a weight of 2440 g (+2.2 SDS), mild dysmorphic features and a cleft palate. A capillary blood glucose (BG) on day 12 was 29 mg/dL and a critical blood sample taken during this hypoglycemic episode revealed serum glucose of 32mg/dL, insulin of 0.65mIU/L, c-peptide of 0.285ng/ml, ketones of 0.2mmol/l and adequate counter-regulatory hormone levels (cortisol 21.9μg/dL, growth hormone 10.9μg/L). Glucagon elicited glucose response without lactate elevation. The patient exhibited cyclical hypo/hyperglycemic episodes during 2-hourly feeding with continuous glucose-monitoring (27-383 mg/dL; time in 55-140 mg/dL range: below 4% and above 9%). Persistent hypoglycemia despite a glucose infusion rate (GIR) of up to 8 mg/kg/min required diazoxide and hydrochlorothiazide. Hypoglycemia persisted despite GIR of 17 mg/kg/min, suggesting diazoxide unresponsiveness. Despite treatment including methylprednisolone (2 mg/kg/day), octreotide (40 mg/kg/day), nifedipine (4x100 mg/kg/dose) and glucagon infusion (1 mg/kg/hour), hypo/hyperglycemia cycling persisted, necessitating continuous nasogastric feeding and octreotide by pump, successfully stabilizing BG. Rapid genetic testing for *ABCC8* and *KCNJ11* variants at Exeter were unremarkable. Next-generation sequencing analysis for *ABCC8, AKT2, CACNA1C, CACNA1D, CREBBP, DNTTIP1, EP300, FOCAD, FOXA2, GCK, GLUD1, GPC3, HADH, HNF1A, HNF4A, INSR, KCNJ11, KDM6A, KMT2D, MAFA, MAGEL2, NSD1, PHOX2B, PMM2, RNF10, SLC16A1, TRMT10A*, and *HK1* variants were also unremarkable. Whole exome sequencing re-analysis for hypoglycemia-associated conditions has been initiated. On continuous feeding at three months old the baby had an episode of hypoglycemia (48.9 mg/dL) with concurrent insulin $<$0.04 mIU/L and c-peptide 0.03 ng/ml confirming HHH. The patient died due to septic shock from complications of influenza pneumonia.

Discussion and Conclusion

HHH is a rare and heterogeneous disorder that can clinically resemble congenital hyperinsulinism (CHI) or other metabolic diseases and may be misdiagnosed, as in this case.. Pathogenic variants in the **phosphoinositide-3-kinase (PI3K)-AKT-mTOR signaling cascade,** have been implicated in HHH, and should be considered in cases of CHI with low measurable insulin levels. Continuous feeding systems, which have demonstrated efficacy in recent reports of HHH ultimately achieved euglycemia in the presented case, although the mTOR inhibitor, sirolimus, has also been effective in some cases.

The effects of long-acting pegylated recombinant human growth hormone (jintrolong) on body composition and bone mass in transitional growth hormone deficiency

Ke Huang[1], Hu Lin[1], Zhiya Dong[2], Yanhong Li[3], Guimei Li[4], Hui Yao[5] & Junfen Fu[1]

[1]Children's Hospital Zhejiang University School of Medicine, Hangzhou, China; [2]Ruijin Hospital Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [4]Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; [5]Wuhan Children's Hospital, Wuhan, China

Objective

The aim of the present study was to evaluate bone mineral density (BMD) and body composition (BC) of patients with transitional growth hormone deficiency (TGHD) treated with once-weekly PEGylated recombinant human growth hormone (Jintrolong) (PEG-rhGH).

Methods

This study was a prospective, multicenter, single arm study with a total of 66 weeks, encompassing a 2-week screening phase, a 12-week dose-adjustment period, and a 52-week treatment phase. The initial dose was 1 mg/w, with subsequent adjustments based on individual IGF-1 levels. BMD and BC were evaluated using dual energy X-ray absorptiometry (DEXA) at baseline, 38 weeks, and 64 weeks.

Results

A total of 31 subjects were included, including 23 males (74.2%) and 8 females (25.8%) with a mean age of 20.46 years. Mean doses in dose stabilization were 3.40 mg/week. The compliance rates nearing 100%. Following a 64-week therapeutic intervention, there was a significant improvement in the IGF-1 Standard Deviation Score (SDS), which increased from a baseline value of -3.07 to -1.38 (P $<$0.001). Significant improvement in BC was observed, manifesting as percentage of body fat (Fat %) decrease by 2.7% (P $<$0.001) and LBM increase by 4.54 kilograms (P $<$0.001), corresponding to a 12% change rate over 64 weeks. Although the lumbar BMD Z-score did not demonstrate statistical significance, there was a numerical increment observed, with an increase of 0.43, elevating the score from -1.54 at baseline to -1.12 post-treatment. In the evaluation of lipid metabolic profiles, a notable decrease was observed exclusively in triglyceride concentrations, which significantly declined from a mean of 1.50 mmol/l to 1.14 mmol/l (P = 0.018). Meanwhile, there was no statistically significant difference in the changes in low density lipoprotein cholesterol (LDL-c), high density lipoprotein cholesterol (HDL-c) and total cholesterol (TC), but there was a tendency for HDL-c to increase.

Conclusion

Our findings indicate that PEG-rhGH therapy is effective in enhancing lean body mass and reducing body fat percentage. These results suggest that PEG-rhGH, with high adherence, may be beneficial in improving BC and BMD in patients with TGHD.

Overgrowth: one patient, two syndromes

Matteo Pontone[1,2], Alessandro Barbato[1,2], Matteo Cerutti[1,2], Eugenio Trinati[1,2], Franco Ricci[1,2] & Stefano Stagi[1,2]
[1]Meyer Children's Hospital IRCCS, Paediatric Diabetology and Endocrinology Unit, Florence, Italy; [2]University of Florence, Department of Health Sciences, Florence, Italy

Background
Sotos syndrome (SS) and Tatton-Brown-Rahman syndrome (TBRS) are two overgrowth syndromes characterized by distinct somatic features and intellectual disability. SS is caused by a heterozygous pathogenic variant in the NSD1 gene, while TBRS is caused by a heterozygous pathogenic variant in the DNMT3A gene.
Case
A 5-year-old patient presented to our hospital with vomiting and unsteadiness of gait. Imaging revealed a neoplasm occupying the third and fourth ventricles of the brain. Histological analysis confirmed the diagnosis of medulloblastoma. On clinical examination, the patient exhibited a height greater than 5 standard deviations (SD) above the mean and a weight greater than 2.5 SD according to the WHO 2006 growth charts. Somatic features were consistent with those seen in SS. Suspecting an overgrowth syndrome, genetic analysis was conducted using exome sequencing (Next Generation Sequencing). This revealed a pathogenic heterozygous variant in the NSD1 gene (c.6455G>A, p.(Arg2152Gln)) and a pathogenic heterozygous variant in the DNMT3A gene (c.2644C>T, p.(Arg882Cys)). Genetic testing of the parents revealed no similar variants, leading to a diagnosis of de novo SS and TBRS.
Conclusion
We present the first case of a patient diagnosed with both SS and TBRS, both arising de novo, in association with medulloblastoma. SS occurs in approximately 1 in 14,000 live births, while TBRS has an incidence of <1 in 1,000,000. Both SS and TBRS are typically transmitted in an autosomal dominant manner, with de novo mutations being the most common cause. Interestingly, the patient's parents are first cousins (with first cousin paternal grandparents), which is known to increase the risk of inherited diseases. However, this patient developed two separate de novo mutations. Both SS and TBRS are associated with an increased risk of neoplasia, particularly within the hematopoietic system. To our knowledge, this is the first case of medulloblastoma reported in a patient with SS, although a previous case of TBRS with medulloblastoma has been described. This case emphasizes the importance of thorough genetic investigation when encountering a patient with an overgrowth syndrome, as clinical features alone may not provide an unambiguous diagnosis. Additionally, while rare, solid tumors should not be overlooked in these patients, and a careful assessment for tumor-related signs and symptoms is crucial.

Clinical and genetic characteristics of cornelia de lange syndrome: a retrospective study of 20 pediatric patients in China

Li Xiaoqiao[1], Ming Cheng[1] & Gong Chunxiu[1]
[1]Department of Endocrinology, Genetics, Metabolism, Beijing Children's Hospital, Capital Medical University, National Center for Children's Health, Beijing, China

Background
Cornelia de Lange Syndrome (CdLS) is a rare genetic disorder characterized by a range of developmental and physical anomalies. This study aims to evaluate the clinical characteristics and genetic variations in 20 pediatric patients diagnosed with CdLS.
Methods
We compared clinical characteristics of 20 patients grouped by genotypes based on whole exon sequencing and performed subgroup analyses according to the presence or absence of null variants.
Results
Comprehensive clinical evaluations revealed that 70% of the patients experienced prenatal growth retardation and short stature, while 85% exhibited global developmental delays. Craniofacial dysmorphisms, such as synophrys, short noses, and anteverted nares, were highly prevalent, observed in up to 90% of the cohort. Additional manifestations included skeletal abnormalities (80% exhibited small hands and/or feet), skin manifestations (30% with hirsutism or mottled skin) , and sensory impairments (20% with hearing loss). Genetic analysis identified variants in the NIPBL (75%), SMC1A (15%), and RAD21 (10%) genes. Null mutations, which result in complete loss of protein function, were significantly associated with the classical CdLS phenotype and corresponded with more severe clinical manifestations, including heightened intellectual disability. Three patients received growth hormone treatment, displaying diverse responses.
Conclusions
Our findings underscore the heterogeneity of clinical presentations in CdLS and emphasize the critical role of the mutation type in determining disease severity. These results warrant further investigations to optimize management strategies and improve understanding of the functional significance of the identified variants.

Development of AI-based growth prediction models for children with growth disorders: a 3-year analysis using the lg growth study

Young Suk Shim[1], Hae Sang Lee[1], Young-Jun Rhie[2], Hyun Wook Chae[3], Jaehyun Kim[4], Young Ah Lee[4], Yoo-Mi Kim[5], Ja Hye Kim[6], Moon Bae Ahn[7], Yong Hee Hong[8] & JIYEON CHOUNG[9]
[1]Ajou University Medical Center, Department of Pediatrics, Suwon, South Korea; [2]Department of Pediatrics, Korea University College of Medicine, Ansan, South Korea; [3]Department of Pediatrics, Yonsei University College of Medicine, Seoul, South Korea; [4]Department of Pediatrics, Seoul National University College of Medicine, Seoul, South Korea; [5]Department of Pediatrics, Chungnam National University Sejong Hospital, Sejong, South Korea; [6]Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, South Korea; [7]Department of Pediatrics, College of Medicine, The Catholic University of Korea, Seoul, South Korea; [8]Department of Pediatrics, Soonchunhyang University Bucheon Hospital, Soonchunhyang University College of Medicine, Bucheon, South Korea; [9]Life Sciences. Corporate Innovation. DX Team(AI Development Part), LG Chem, Seoul, South Korea

Background
Growth hormone (GH) treatment is effective in improving growth outcomes in children with various growth disorders, including growth hormone deficiency (GHD), idiopathic short stature (ISS), small for gestational age (SGA), and Turner syndrome (TS). However, individual responses to GH therapy vary, necessitating predictive models to guide personalized treatment strategies. Previous models have primarily focused on short-term outcomes using regression methods. This study aimed to develop machine learning-based models to predict growth outcomes up to 3 years after treatment initiation and improve accuracy through ensemble learning, using data from the LG Growth Study (LGS). Turner syndrome patients were limited to females.
Methods
Prepubertal children with GHD, ISS, SGA, and female children with TS were included in this study. Clinical and demographic features were collected at the screening visit, including baseline height and weight, age, sex, mid-parental height, bone age, diagnosis, and initial GH dose. Machine learning models (TabNet, XGBoost, LightGBM, CatBoost) were used to predict growth outcomes at 1-, 2-, and 3-years post-treatment. A Weighted Ensemble model was constructed using root mean squared error (RMSE)-based weights. Model performance was evaluated using mean absolute error (MAE), mean squared error (MSE), RMSE, mean absolute percentage error (MAPE), and the coefficient of determination (R^2).
Results
The Weighted Ensemble model achieved superior accuracy for 1-year predictions with an RMSE of 1.95 and R^2 of 0.983. TabNet demonstrated better performance for mid-term predictions, achieving RMSEs of 2.975 (R^2 0.961) at 2 years and 3.674 (R^2 0.937) at 3 years. The Weighted Ensemble maintained overall stability and consistent performance. However, predictions beyond 3 years showed a decline in accuracy across all models.
Conclusion
This study demonstrates that AI-based models can provide accurate growth predictions for children with various growth disorders over the first 3 years of GH treatment. TabNet showed the highest performance in mid-term predictions, while the Weighted Ensemble offered overall stability. Future research should aim to improve long-term prediction accuracy by integrating additional clinical data and advanced time-series methods.

The molar ratio of IGF-1/IGFBP-3 serves as a biomarker for evaluating the therapeutic efficacy of recombinant human growth hormone

Xiyu He[1] & Xiumei He[1]
[1]Fifth Medical Center, Chinese People's Liberation Army General Hospital, Beijing, China

Background
Insulin-like growth factor-1 (IGF-1) is widely recognized as a key parameter for monitoring the therapeutic effects of rhGH and guiding treatment adjustments. However, the majority of growth responses are influenced by the concentration differences between IGF-1 and IGFBP-3. For biologically active substances, the molar ratio of IGF-1/IGFBP-3 more accurately reflects changes in biological activity. Therefore, this study aims to investigate the value of the IGF-1/IGFBP-3 molar ratio in assessing the therapeutic efficacy of rhGH.
Methods
This study included 67 children with short stature who received recombinant human growth hormone (rhGH) treatment. Participants were categorized into three groups based on etiology: growth hormone deficiency (GHD) ($n = 18$), idiopathic short stature (ISS) ($n = 37$), and small for gestational age (SGA) ($n = 12$). The primary outcome measures included the changes in IGF-I SDS and the IGF-I/IGFBP-3 molar ratio SDS at baseline and at 3, 6, 9, and 12 months post-treatment, as well as their correlation with the rhGH treatment dose and changes in height SDS. The treatment effect was also evaluated (a ΔHt-SDS $\geq$ 0.5 SDS increase in height standard deviation within 1 year of treatment was considered a good treatment effect).
Results
After one year of rhGH treatment, all groups showed significant increases in IGF-1 SDS, IGF-1/IGFBP-3 molar ratio SDS, and height SDS compared to baseline ($P < 0.05$). During the treatment period, rhGH dose was positively correlated with both IGF-1 SDS ($r = 0.773$, $P < 0.001$) and IGF-1/IGFBP-3 molar ratio SDS ($r = 0.843$, $P < 0.001$). The trends in IGF-1 SDS and IGF-1/IGFBP-3 molar ratio SDS paralleled those in height SDS. Among the 46 patients with a good treatment response, the IGF-1/IGFBP-3 molar ratio SDS was significantly higher compared to those with a poor response ($P < 0.01$).
Conclusion
The molar ratio of IGF-1/IGFBP-3 is an important biomarker for evaluating the therapeutic effect of growth hormone and provides a theoretical basis for formulating individualized clinical treatment strategies.
Key words
Growth hormone deficiency; Small for gestational age; Idiopathic short stature; Recombinant human growth hormone; Molar ratio of IGF-1/IGFBP-3

Celiac disease and short stature: sometimes it is not just gluten

Irene Karatsoli[1], Sokratis Katsoudas[1], Polychroni Ioulia[2] & Lela Stamogiannou[3]
[1]General Hospital Of Nikaia, Pediatric Endocrinology Unit, Nikaia, Greece; [2]Private Pediatric Endocrinology Unit, Neo Hrakleio, Greece; [3]IASO Pediatric Hospital, Pediatric Endocrinology Unit, Athens, Greece

Introduction
Celiac disease (CD) is an autoimmune disorder in which gluten ingestion triggers an immune response, leading to small intestinal damage and impaired nutrient absorption. This can result in various symptoms such as diarrhea, weight loss, fatigue, and bloating, though some patients may be asymptomatic. CD is also associated with extra-intestinal complications, including endocrine manifestations. In some cases, short stature may be the only clinical sign of CD. The primary treatment is a strict, lifelong gluten-free diet (GFD). We present a case of a female patient with CD and idiopathic Growth Hormone (GH) Deficiency (GHD), underlying the need for continuous monitoring of growth response post-GFD.
Methods
A 10-year, 6-month-old prepubertal girl (Tanner stage I) was evaluated for short stature. Her growth rate was 2.5 cm/year, and her height and weight were below the 3rd percentile. Her medical history was unremarkable, except for chronic constipation since infancy, managed with macrogol. Laboratory tests revealed IGF-1: 71 ng/ml, tTG-IgA: 116.4 U/ml, and IgA: 144 mg/dL. A gastroenterological evaluation, including biopsy, confirmed mild chronic enteritis consistent with a malabsorption syndrome. She was started on a GFD and monitored every six months.
Results
After two years on a GFD, her tTG-IgA levels normalized, but her growth rate did not improve as expected. Further endocrinological assessment confirmed GHD. The patient started GH therapy, and over the next four years, she gained 25.5 cm in height.
Conclusion
GH secretion should be evaluated in children with CD who fail to achieve expected growth recovery despite adherence to a GFD and normalized tTG-IgA levels. The exact pathophysiological link between CD and idiopathic GHD remains unclear, but their coexistence suggests a potential association. This case highlights the importance of a multidisciplinary approach in the early diagnosis and management of growth disorders in children with CD. Pediatric endocrinologists and general pediatricians should be monitoring growth response post-GFD initiation to ensure timely intervention if GHD is present.

Rare case of DPH1 syndrome: report of a patient with two novel variants

Olga Nioti[1], Pinelopi Smyrnaki[2], Iliana Maniadaki[3], Paraskevi Xekouki[4] & Constantine Stratakis[5]
[1]Pediatric clinic, Lausanne University Hospital, Lausanne, Switzerland; [2]Pediatric Endocrinology and Diabetes Clinic, Heraklion, Greece; [3]Pediatric clinic, University General Hospital of Heraklion, Heraklion, Greece; [4]Endocrinology and Diabetes clinic, University General Hospital of Heraklion, Heraklion, Greece; [5]Human Genetics & Precision Medicine, IMBB, FORTH, Crete, Heraklion, Greece

Introduction
Diphthamide-deficiency (DPH1) syndrome is a rare autosomal recessive neurodevelopmental disorder characterised by variable degrees of developmental delay, dysmorphic features, sparse hair, hand/foot and genital anomalies, short stature and central nervous system malformations. To date, less than 20 cases have been reported in the litterature. Here, we present a case of patient with two novel DPH1 gene variants.
Case presentation
A one year old boy was referred to the pediatric endocrinology clinic for non autoimmune hypothyroidism (TSH 13.8 μIU/ml). The patient was a full term infant presenting with mild psychomotor delay, sparse hair, strabismus, syndactyly, valgus deformity of the feet and a history of unilateral cryptorchidism and bilateral inguinal hernia. His growth development was normal. Thyroid ultrasound was unremarkable and treatment with levothyroxine was initiated. Neurologic evaluation after normalisation of thyroid function confirmed a mild psychomotor delay (mostly hypotonia). During followup, patient's growth velocity progressively declined with his height falling below parental target. Bone age was delayed by one year. Laboratory testing confirmed growth hormone (GH) deficiency and GH treatment was started. Brain MRI revealed a mild ventricular dilatation, a thin corpus callosum and a small sized pituitary gland. As part of the investigation of the patient's multiple pathologies, whole exome sequencing (WES) study was performed, detecting a maternally inherited heterozygous c.907-1delG intronic variant expected to lead to a loss of protein function (in silico analysis) and a paternally inherited c.284C>T (p. Thr95Met) variant) variant of unknown significance in the *DPH1* gene.
Conclusion
Loss of function *DPH1* gene variants affect diphtamide biosynthesis, a post-translationaly modified histidine residue crucial for cell division and embryonic development, leading to cell death and growth defects. We report two novel *DPH1* variants, in a patient with clinical features consistent with those previously described in DPH1 syndrome. Although further studies are required to confirm the functional impact of these variants, this case highlights the expanding genotypic spectrum of DPH1 syndrome and emphasizes the importance of considering this diagnosis in patients with compatible clinical presentation.

Osteogenesis imperfecta/ehler danlos overlap syndrome

Dhanya Soodhana[1], Nafiya Palakkadath[1] & Divya Pachat[1]
[1]Aster Malabar Institute of Medical Sciences, Kozhikode, Department of Pediatrics, Kozhikode, India

Ehlers–Danlos syndrome (EDS), osteogenesis imperfecta (OI), and cutis laxa (CL) are three rare and heterogeneous connective tissue disorders. Patients with these syndromes have similar manifestations and unpredictable prognosis, making a misdiagnosis highly probable. Osteogenesis imperfecta/Ehlers–Danlos (OI/EDS) overlap syndrome is a recently described disorder of connective tissue, characterized by mutation of *COL1A1* (17q21.33) or *COL1A2* (7q21.3) genes. 3-year-old boy 2nd born of a non-consanguineous parentage with no significant

antenatal and neonatal complaints presented with a delay in attaining age-appropriate milestones. The child had history of recurrent fractures following trivial injuries. The first fracture occurred at the age of one year, affecting the first metacarpal bone of the right hand. The second fracture took place at one and a half years, involving the radius on the right. The third was located at the proximal phalanx of the left toe. The mother had also noted easy bruising. Failure to thrive was noted during follow up visits. Evaluation revealed short stature (85cm, -3 SDS), poor weight gain (10 kg, -3SDS). His head appeared large, he had frontal bossing, blue sclera, generalized joint laxity, hypotonia, contractures in the fingers of the left hand, and loose skin folds. His Beighton score was 7/9. Investigations done revealed normal serum calcium (2.57 mmol/l), vitamin D (147 nmol/l), alkaline phosphatase (233 IU/L) and parathormone levels (1.8 pmol/L). Other endocrinological causes of short stature were ruled out. Additionally, the DXA scan report confirmed the presence of osteoporosis (Z score -3.8 SD). Echocardiography done was normal. History of similar complaints was noted in the father, he had walked late, history of recurrent fractures and hyper mobile joints. His Beighton score was 7 out of 9. A suspicion of collagenopathy, specifically Ehlers-Danlos syndrome, osteogenesis imperfecta spectrum was raised. Whole exome sequencing done showed a pathogenic, heterozygous mutation in the COL1A2 gene on intron 9, variant c.432 + 1G > A which was suggestive of combined osteogenesis imperfecta and Ehlers Danlos Syndrome type 2 which has an autosomal dominant inheritance. Genetic testing of the father not done due to financial constraints. The child has been started on bisphosphonate therapy with zoledronic acid and is on regular follow up. OI/EDS overlap syndrome is a rare collagenopathy requiring high clinical suspicion for diagnosis. This case underscores the role of genetic testing in confirming the disorder, especially with a positive family history. Early bisphosphonate therapy can reduce fracture risk, thereby enhancing the quality of life for affected individuals.

Growth hormone testing in prader willi syndrome: our experience with glucagon test

Roberta Pajno[1], Maria Rosaria Galati[1], Agnese Solmi[1], Beatrice Volpe[1], Stefano Mora[1], Carmen Bucolo[1] & Gianni Russo[1]
[1]IRCCS San Raffaele Hospital, Milan, Italy

Background
Prader-Willi Syndrome (PWS) is a rare genetic disorder characterized by neonatal hypotonia, hyperphagia, obesity and multiple endocrine abnormalities, including short stature and growth hormone deficiency (GHD). In Italy, the "Note AIFA 39" regulates the use and refund of Growth Hormone (rGH) therapy by the National Health System. In PWS children treatment with rGH can be started without stimulation tests to demonstrate GHD. However, after the achievement of final height, stimulation tests must be taken to confirm GHD before resuming treatment in PWS late adolescents and adults. Most studies use the growth-hormone-releasing hormone plus arginine (GHRH-arginine) test or, less frequently, the insulin tolerance test (ITT). Due to the shortage of GHRH-arginine, starting from October 2023, AIFA authorized the use of glucagon stimulation test (GST) to assess GH status in GHD adult patients. Few data are available on GST in PWS.
Aim
This study aims to investigate GHD with GST in PWS patients during the transition phase.
Methods
We retrospectively analyzed peak GH concentrations in ten late adolescent PWS patients followed at our Center (5 males and 5 females; median age 16,1 y; median BMI 25,7 kg/m^2) who underwent GST after discontinuing GH treatment for at least 4-6 weeks. These patients discontinued treatment at achievement of final height as defined by a growth velocity $<$ 1 cm/year and the epiphyseal closure demonstrated by bone age evaluation. GHD was defined as a peak GH concentration (GHp) $<$ 3 ng/ml.
Results
Three patients met the criteria for GHD status (peak GH concentration $<$ 3 ng/ml) and resumed growth hormone therapy. Instead, seven patients suspended the therapy as the peak GH concentration was higher than cut-off. A moderate negative correlation was found between GHp and BMI (r = -0.52, P = 0.123), suggesting that GH response decreased with increasing BMI, but no significant correlation with age was observed. Gender did not significantly influence GH response.
Conclusions
GST is a reliable, safe and inexpensive alternative to the GHRH-arginine test for diagnosing GHD in adult PWS patients. However, BMI-related criteria should be considered, especially in overweight and obese patients. Resuming GH therapy in GHD adult PWS patients during the transition phase showed positive effects in order to preserve body composition and quality of life. Further studies are needed to define the accuracy of GST for GHD screening in PWS during the transitional age.

Disease activity drop-off in elderly patients with active acromegaly over a median follow-up period of ten years: a longitudinal, restrospective study

Alessio Bellelli[1], Chiara Diazzi[1], Sara De Vincentis[2] & Vincenzo Rochira[3]
[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy, Modena, Italy; [2]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [3]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy

Introduction
GH-IGF-1 axis activity declines with aging. Acromegaly. Central GH regulation is retained at least in part in acromegaly, despite autonomous GH secretion. However, changes of GH-secreting tumor function in the elderly remain unclear.
AIM
To investigate GH-IGF-1 axis functional changes overtime in GH-secreting adenomas in terms of acromegaly disease activity in relation to advancing age.
Methods
A retrospective, longitudinal study involving 31 adult patients with active acromegaly was conducted at a single centre over an extended follow-up period from February 2008 to October 2024. At each visit, comprehensive patient data were collected including acromegaly-specific medical history, detailed medication history (start date, duration, dosage, and withdrawal information), biochemical parameters (from a single laboratory) and comorbidities. Acromegaly control was assessed using IGF-1 ULN (ULN1) alone or in relation to ongoing therapy as a product of each [for cabergoline (cab), octreotide (octr), lanreotide (lan), pegvisomant (peg)] drugs daily dose and the corresponding ULN value (ULN1*cab dose, ULN1*octr dose, ULN1*lan dose, ULN1*peg dose). This analysis was also repeated for IGFBP-3 (ULN2) and the relative product based on drug daily dose (ULN2*cab dose, ULN2*octr dose, ULN2*lan dose, ULN2*peg dose).
Results
Serum IGF-1 ($p < 0.001$), IGFBP-3 ($p < 0.001$), ULN1 ($p < 0.001$), and ULN2 ($p < 0.001$) trajectories overtime were inversely related to the time to disease relapse/onset. The inverse trajectory over time was particularly evident for ULN1*cab dose ($p < 0.001$), ULN1*octr dose ($p < 0.001$), and ULN1*peg dose ($p < 0.001$). The same trajectories showed a similar trend for ULN2*cab dose and ULN2*peg dose. The temporal trajectories of ULN1*lan dose (P = 0.278) and ULN2*lan dose did not change significantly over time (P = 0.409). The ULN2*octr dose trajectory overtime showed a trend in reduction but did not reach statistical significance (P = 0.064).
Conclusion
This study suggests that disease activity decreases in older acromegalic patients by the progressive evolution towards a less aggressive disease. Significantly, this research demonstrates as novel observation a decline in the ULN of IGF-1 (ULN1) and IGFBP-3 (ULN2) over time, even after adjusting for daily medication dosage. Improving knowledge on the natural history of acromegaly disease in terms of disease activity modifications during aging and long-term follow-up will enable optimizing therapeutic decisions and drug dosage titration finally minimizing the risk of overtreatment.

Clinical heterogeneity of sanjad sakati syndrome: experience from a single tertiary center in kuwait

Wafaa Laimon[1], Hajer Alotaibi[2], Dalia Al-Abdulrazzaq[1,3,4], Reham Ebrhim[1], Jawad Mirza[1] & Iman Al-Basari[1]

[1]Mubarak Al Kabeer Hospital, Ministry of Health, Department of Pediatrics- Pediatric Endocrinology and Diabetes unit, Kuwait, Kuwait; [2]Ministry of Health, Kuwait, Kuwait; [3]College of Medicine, Department of Pediatrics, Kuwait, Kuwait; [4]Dasman Diabetes Institute, Department of Population Health, Kuwait, Kuwait

Background
Sanjad-Sakati Syndrome (SSS) is a rare autosomal recessive disorder predominantly reported in individuals of Arab descent. The hallmark endocrinological feature of SSS is primary hypoparathyroidism.
Aim
To define the clinical phenotypes and common complications of SSS in a Kuwaiti cohort.
Subjects and methods
This retrospective study included 17 patients from 14 families with SSS who were diagnosed, treated, or referred for follow-up at our center between 2005 and 2024. Their data were collected and analyzed.
Results
Seventeen patients (10 females, 59%) were recruited with median age of 10.7 years. Consanguinity was present in 9/14 families (64%). All patients were homozygous for *TBCE* founder mutation (c.155_166del; p. Ser52-Gly55del). One patient was additionally homozygous for the c.157+8A>T splice-site variant in intron 2 of ABCD4 gene, associated with methylmalonic aciduria and homocystinuria- an association not previously reported with SSS. The mean age of presentation was 34 days, primarily due to symptomatic hypocalcaemia. The main referral reasons were neonatal seizures (10/17), apnea (2/17) and poor activity (3/17). Dysmorphic features were present in all patients, including deep seated eyes, low set ears and peaked nose. Hypomagnesemia was observed in 24%, and 59% developed bilateral medullary nephrocalcinosis (median age: 3.5 years), with one of them progressing to end stage renal disease. All patients have hypoparathyroidism, while 18% have autoimmune hypothyroidism, 18% have adrenal insufficiency, and 41% experienced delayed puberty. Additionally, one patient has autoimmune hyperthyroidism, and one has growth hormone deficiency. Gastrointestinal manifestations included gastroesophageal reflux disease (41%), chronic constipation (18%) and recurrent intestinal obstruction (18%). Immune dysfunction was observed in 18%, characterized by reduced CD4 counts and low antibody response to vaccines. Ophthalmologic abnormalities were noted in 35%, including refractive errors and corneal opacity in one patient. Bilateral basal ganglia calcifications were present in 29%, with epilepsy diagnosed in two patients. MRI brain findings in three patients revealed corpus callosum and white matter volume loss with small pituitary gland. Nocturnal ventilatory support with bi-level positive airway pressure was required in 35% of patients. The mortality rate was 18% with septic shock as the leading cause of death.
Conclusion
SSS is a rare multisystem genetic disorder with significant morbidity and mortality. The novel association with ABCD4-related methylmalonic aciduria and homocystinuria expands the genetic and phenotypic spectrum of the disease. Given the high burden of complications, early diagnosis, multidisciplinary management, and vigilant long-term follow up are essential for optimizing patient outcomes.

Short stature in CHARGE syndrome

Maria Luboińska- Cebula[1] & Robert Śmigiel[1]
[1]Wroclaw Medical University, Clinic of Pediatrics, Endocrinology, Diabetology and Metabolic Diseases, Wroclaw, Poland

CHARGE syndrome is a rare monogenic syndrome of congenital defects with a diverse clinical picture, occurring with a frequency of 1: 100 thousand births. CHARGE syndrome is caused by a disturbance in the function of the CHD7 gene, which encodes a protein that is a transcription regulator that binds to elements in the nucleoplasm and enhances the biogenesis of ribosomal RNA (another transcription element). The name CHARGE is an acronym of the first letters of the following developmental defects: C (coloboma) eye cleft (80-90%), H (heart defect) heart defect (60-85%), A (atresia choanae) choanal atresia (55-85%), R (retarded growth) growth and cognitive development disorder (70-85%), G (genital hypoplasia) genital abnormalities (53-100%) E (ear anomaly) dysmorphia of the auricles and hearing loss typical of the syndrome. In approximately 90% of patients, agenesis of the semilunar canals also occurs. Clinical diagnosis of CHARGE syndrome requires the detection of four defects from the group of major criteria or three major and three minor criteria, as well as confirmation of a pathogenic variant in the CHD7 gene. Short stature is one of the minor criteria. There may be many causes of growth deficiency: difficulties in feeding, co-occurrence of systemic defects or growth hormone deficiency. The aim of the study is to assess the effectiveness of growth hormone treatment in children with CHARGE and short stature. An analysis of 29 patients with CHARGE syndrome confirmed by a mutation in the CHD7 gene was carried out. The youngest of the analyzed patients is 6 months old, the oldest is 24 years old. The average birth weight is 2997.4 g, length 52.1 cm. All analyzed patients were burdened with developmental defects, as many as 83% of patients have a heart defect. Growth < 3pc was found in 76% of patients, but only two patients are currently treated with growth hormone due to somatotropin-dependent pituitary insufficiency. During the treatment they did not achieve 3pc height, but an improvement in growth was achieved, expressed as a decrease in the standard deviation of growth.
Conclusions
1. The vast majority of children with CHARGE syndrome are short, but only a few patients are qualified for the diagnosis of somatotropin hypopituitarism and qualified for treatment with recombinant growth hormone.
2. Only two patients with CHARGE syndrome (6.9%) analyzed in the study are treated with rhGH. As a result of using rhGH, an improvement in growth velocity was achieved.

15q26.3 Deletion effect on growth: a case report

Catarina Gama[1], Francisca Manoel[2], Vitória Cadete[3], Rita Pereira[4], Ana Laura Fitas[5] & Lurdes Lopes[5]
[1]Unidade Local de Saúde de Lisboa Ocidental - Hospital de Egas Moniz, Endocrinology, Lisboa, Portugal; [2]Unidade Local de Saúde Alentejo Central- Hospital do Espírito Santo de Évora, Paediatric Unit, Évora, Portugal; [3]Unidade Local de Saúde S. José, Hospital Dona Estefânia, Lisboa, Portugal; [4]Unidade Local de Saúde S. José, Hospital Dona Estefânia, Paediatric Endocrinology Unit, Lisboa, Portugal; [5]Hospital Dona Estefânia, ULS S. José, Paediatric Endocrinology Unit, Lisboa, Portugal

Introduction
Insulin-like growth factor 1 (IGF-1) is essential for prenatal and postnatal growth, acting through the IGF1 receptor (IGF1R), a tyrosine kinase encoded by the IGF1R gene, located on the distal arm of chromosome 15 (15q26.3). Deletions of 15q26 are rare chromosomal abnormalities, typically associated with a variable degree of intrauterine growth restriction (IUGR), postnatal growth failure, developmental delay, microcephaly, intellectual disability, among other congenital anomalies.
Case Report
A five-year-old girl was referred to endocrinology clinic for short stature. Family history revealed a short stature mother (147.5 cm, -2.42 SDS) and an otherwise normal-height family, without consanguinity. Pregnancy was uneventful until 34 weeks of gestation, when IUGR and microcephaly were detected. A C-section was performed at 35 weeks and 5 days. Birth somatometry: height 42.7 cm [-1.5 standard deviation score (SDS)], weight 1930 g (−1.40 SDS) and head circumference 29.5 cm (-1.6 SDS). Due to prenatal ultrasound findings, genome-wide array analysis was performed in cord blood. A 214 kb terminal deletion at a single copy of 15q26.3 was reported, resulting in a partial deletion of IGF1R. She was followed-up at general paediatrics, with a height around -2 SDS until 12 months. She was lost to follow-up during COVID-19 pandemic. From three-years-old on, the height has been around -3 SDS. At the first visit: height 96.3 cm (-2.78 SDS), weight 12.4Kg (-2.83 SDS) and BMI 13.4kg/m2 (-1.42 SDS). Neither dysmorphic features nor development delay were noted. Growth velocity was 4.3 cm/year. Laboratory investigation showed adequate IGF1 [204.0 ng/ml, reference range (RR): 63.6-250.0] and IGF binding protein 3 (4.14 µg/ml, RR: 2.203-5.202) levels; a female karyotype (46, XX); bone age of 3 years old. The 15q26.3 deletion was also identified in the mother. The patient remains under regular follow-up with the endocrinology team and growth hormone (GH) therapy is being considered.
Discussion
This patient's findings suggest a partial IGF-1 resistance, resulting in short stature. The deletion at 15q26.3 might explain these findings. Heterozygous mutations typically reduce IGF1R expression or impair signalling, rather than complete receptor loss. The variable phenotype, which is not yet fully understood, presents a management challenge as in our case. The positive effects of GH treatment may result from its direct stimulatory action or elevated IGF-1 levels, which are expected to activate partially insensitive receptors.

JOINT2357

Is L-dopa test effective in detecting adrenal insufficiency with preliminary diagnosis of growth hormone deficiency in children with short stature?

Gülümay Vural Topaktaş[1], Eren Er[1], Sevim Onguner[1], Benay Turan[1] & Bumin Nuri Dündar[2]

[1]Izmir City Hospital, Pediatric Endocrinology Clinic, Izmir, Türkiye; [2]Izmir Katip Celebi University, Faculty of Medicine, Department of Pediatric Endocrinology, Izmir, Türkiye

Background

Growth hormone(GH) deficiency in children is characterized by impaired linear growth and reduced growth velocity, necessitating confirmation through two GH stimulation tests. At the time of diagnosis, approximately 4% of children with GH deficiency exhibit concomitant adrenocorticotropic hormone(ACTH) deficiency, a prevalence that increases to 12% over the course of follow-up. The insulin tolerance test(ITT) is regarded as the gold standard for assessing both cortisol and GH secretion; however, its clinical application is constrained by potential risks and the requirement for close medical supervision.

Objective

This study aims to evaluate the effect of the L-dopa stimulation test on cortisol secretion in pediatric patients with short stature.

Materials-Methods

This retrospective study included 160 pediatric patients(74 females, 86 males) who underwent the L-dopa stimulation test for the assessment of GH deficiency at the Pediatric Endocrinology Clinic between January 2010 and December 2023. Serum cortisol concentrations were measured at the 90th and 120th minutes of the test. Patients with a peak cortisol response <18 µg/dL subsequently underwent a low-dose(1 µg) ACTH stimulation test to further evaluate adrenal function. Clinical, anthropometric, and biochemical data were extracted from medical records and subjected to statistical analysis.

Results

The mean age of the individuals was 9.5 ± 3.6 years, with 74(46.3%) female and 86(53.7%) male patients. The mean height standard deviation score (SDS) was -2.70 $\pm$ 0.89, the mean weight SDS was -1.84 $\pm$ 1.11. The mean peak GH response was 7.04 $\pm$ 5.28 ng/ml following the clonidine stimulation test and 5.55 $\pm$ 4.21 ng/ml following the L-dopa test. A total of 61 patients exhibited a peak cortisol response <18 µg/dL during the L-dopa test. Among these, 26 underwent a low-dose ACTH stimulation test, and 9 patients (34.6% of those tested; 5.6% of the total cohort) were diagnosed with adrenal insufficiency, defined as a peak cortisol response <18 µg/dL. These patients were initiated on oral hydrocortisone therapy. Comparative analyses between patients with normal vs impaired ACTH test responses (<18 µg/dL vs. ≥ 18 µg/dL) revealed no statistically significant differences in peak cortisol response to the L-dopa test, peak GH response to clonidine or L-dopa, age at presentation, gender, weight SDS, or height SDS.

Conclusion

The L-dopa stimulation test may represent a valuable adjunctive tool for the evaluation of cortisol sufficiency in pediatric patients undergoing assessment for suspected GH deficiency. However, further prospective studies with larger sample sizes and standardized protocols are warranted to validate its diagnostic accuracy and clinical utility in detecting adrenal insufficiency.

Treatment responce of the growth hormone in 3M syndrome: a single center experience

Ilayda Altun[1], Elvan Bayramoğlu[1], Hasan Karakas[1], Mert Uçar[1], Gökçe Velioğlu Haşlak[1], Abdurrahman Güney[1], Dilek Uludağ Alkaya[1], Olcay Evliyaoglu[1] & Hande Turan[1]

[1]Istanbul University Cerrahpasa, Cerrahpasa Medical Faculty, Pediatric Endocrinology, Istanbul, Türkiye

Introduction

3MSyndrome is autosomal recessive inherited dwarfism, characterized by pre and postnatal growth retardation. 3Msyndrome develops as a result of biallelic loss of function mutations in cullin7(CUL7), obscurin-like1(OBSL1), and coiled-coil domain- containing protein8 genes(CCDC8) are responsible for p53 dysfunction, growth hormone(GH) and/or IGF1 resistance. The aim of this study is to evaluate the the growth hormone(GH) axis and response to GH treatment in 3M syndrome patients.

Methods

Medical records of eight patients followed up with short stature in our Pediatric Endocrinology department and diagnosed with 3M syndrome based on the results of genetic tests, between 2015 and 2024 were recorded. Serum basal levels of IGF1 were determined using immunoradiometric assays. All patients underwent a growth hormone stimulation test(GHST) were performed with levodopa and clonidine. Insulin-like growth factor(IGF) generation test was performed on those with sufficient GHST results.

Results

A total of 8 patients(four males and four males)from 7 families with 4,94(3,5–11,7) years median age at the time the GH treatment started were included in this study and were followed for one to eight years. Out of 7 families, six were consanguineous, one unrelated. All of the patients were born at term. The mean SDSs of birth weight and length of the patients were $-3,15 \pm 1$, $-4,0 \pm 0.60$, respectively. The median height SDS at admission was $-4,30((-7,27)$-$(-2,75))$SDS, and the median midparenteral height SDS was –0,76SDS($(-1,68)$- (-0,27)). The partial deficiency was detected in three cases, severe deficiency in one case. IGF generation test was performed in three cases and all were responsive. Despite described growth hormone (GH) insensitivity in 3M syndrome, all our patients either with GH deficiency or with normal GH levels were treated with GH. The percentile improved in all patients. The median annual growth velocity in the first year of treatment (6,1 cm/year) and in last follow up (5,85 cm/year) was higher compared to pre- treatment levels(5,3 cm/year) (p:0,017). The final height SDS of two cases were – 4,3 SDS and – 4,11SDS because of closure of the growth plates.

Discussion

Although the annual height growth rates of patients under treatment are insufficient, their final heights have been found to be higher compared to those of patients who were followed without treatment in the literatüre. Even the absence of worsening in height SDS in patients receiving growth hormone may be considered as a good response to treatment. It is difficult to reach a conclusion about the efficiency of GH treatment in 3M syndrome patients.

"A shared GHSR gene variant in children with short stature and growth hormone deficiency: potential clinical relevance"

Rawah Mohamed[1,2], Anju Jacob[3], Mohamed El-Abiary[1], Nandu Thalange[1] & Sarah Ehtisham[3]

[1]AL Jalila Children's Specialty Hospital, MBRU, Dubai Health, Pediatric Endocrinology, dubai, United Arab Emirates; [2]AlJalila Children's Speciality Hospital, Pediatric Endocrinology, Dubai, United Arab Emirates; [3]AL Jalila Children's Specialty Hospital, MBRU, Dubai Health, dubai, United Arab Emirates

Background

Growth hormone secretagogue receptor (GHSR) mutations are implicated in growth disorders due to disrupted growth hormone (GH) regulation. We describe three pediatric cases with short stature, all carrying the same genetic variant in GHSR (c.422G>T; p.Arg141Leu). This variant, classified as a variant of uncertain significance (VUS), is suspected to have clinical relevance, particularly in cases from a geographically clustered region with consanguineous backgrounds and consistent phenotypic features of partial growth hormone deficiency (GHD).

Cases and Clinical Details

We evaluated three unrelated consanguineous cases from nearly the same geographic area within the United Arab Emirates:

- **Case 1:** 4-year-old female, birth weight 3.2 kg, height SDS -2.5, weight SDS -2.97. Bone age lagged at -1.24 SDS. Arginine-stimulated peak GH level was 6.71 ng/ml. Serum IGF-1 was 57 ng/ml, and IGFBP-3 was 1,767 ng/ml. NGS stature panel revealed a heterozygous GHSR c.422G>T variant. MRI of the sella showed a small anterior pituitary gland.
- **Case 2:** 7-year-old male, birth weight 3.2 kg, height SDS -2.42, weight SDS -2.4. Bone age lagged at -1.52 SDS. Peak GH with arginine stimulation was 6.78 ng/ml. IGF-1 was 31.8 ng/ml, and IGFBP-3 was 1,847 ng/ml. The stature panel identified a homozygous GHSR c.422G>T variant. MRI revealed a small anterior pituitary.
- **Case 3:** 9-year-old male, birth weight 3.2 kg, height SDS -2.87, weight SDS -3.13. Bone age lagged at -1.87 SDS. Peak GH level was 2.95 ng/ml. IGF-1 was 42.1 ng/ml, and IGFBP-3 was 2,486 ng/ml. A homozygous GHSR c.422G>T variant was identified. MRI of the sella also showed anterior pituitary hypoplasia.

Results

All three patients exhibited features of isolated partial GHD, with suboptimal peak GH responses on stimulation testing despite low-normal IGF-1 and IGFBP-3 levels. The shared GHSR mutation (p.Arg141Leu), identified as autosomal dominant or recessive, may contribute to impaired GH axis regulation. The small

anterior pituitary volumes in all cases suggest a structural component related to the variant's pathogenicity.
Conclusion
The recurrent GHSR c.422G>T (p.Arg141Leu) variant in patients from nearly the same geographic area with consistent phenotypic presentations highlights a potential disease-causing role. While classified as a VUS, our findings support further investigation of its contribution to partial GHD. Longitudinal follow-up and functional studies may help clarify its pathogenicity and guide therapeutic decision-making.

Introduction
Recombinant Human Growth Hormone (GH) was approved in the US (2000) and Europe (2001) for children with Prader-Willi Syndrome (PWS) to improve growth and body composition, with reported benefits in cognition, motor skills and behaviour. However, longer term safety and efficacy data of GH in PWS are still lacking and may be difficult to interpret due to lack of consistency in data collection among studies. This study aimed to identify the minimum dataset (MDS) that could be measured in a routine clinical setting across the world, to minimise burden on clinician data entry and improve quality of data collection to facilitate future studies on long term outcomes.
Methods
The study was undertaken by the PWS Expert Working Group in GloBE-Reg, an international registry platform which supports studies on long-term safety and effectiveness of drugs. Twelve clinical experts on PWS from 10 countries and two patient representatives collaborated to develop this recommendation, based on previously published methodology (Chen *et al*. Horm Res Pediatr 2023). Data fields that achieved 70% consensus in terms of importance qualified for the MDS, provided <50% deemed the item difficult to collect. Several anomalies to the MDS rule were discussed to formulate the final MDS recommendation.
Results
In total, 294 items were compiled from routine clinical practice with 33 redundant items removed and 261 items subjected to the grading system. 151/261 items achieved consensus as important data to collect when monitoring children with PWS on GH treatment, while 218/261 items were deemed easy to collect. Combining both the criteria for importance and ease of collection, 126 items fulfilled the MDS requirement. Four items were designated as core data, two were computed fields, five reassigned as non-MDS, 13 removed as unrelated to safety and effectiveness and 65 were merged into 18 fields. Several anomalies which did not fulfill MDS criteria were also extensively discussed to determine its validity within the MDS, in particular family history of Type 2 diabetes, change of GH therapy (if applicable) and adherence, to produce the final MDS recommendations of 58 items; of which 24 are only to be completed once.
Conclusions
This exercise has identified by consensus the minimum dataset considered necessary, which can be collected through real-world data, to provide consistency and comparability in global studies for monitoring the safety and effectiveness of GH in children with PWS, applicable to the current daily preparations and potential newer long-acting GH.

Three decades of growth hormone therapy in prader-willi syndrome: insights from belgium

Lore Therssen[1], Beckers Dominique[2], Chivu Olimpia[3], sylvia Depoorter[4], De Schepper Jean[5], Hilde Dotrement[6], Claudine Heinrichs[7], Lysy Philippe[8], Anne-Simone Parent[9], Reynaert Nele[10], Saskia Van der Straaten[11], Thomas Muriel[12] & Anne Rochtus[1]
[1]University Hospitals Leuven, University of Leuven, Pediatrics, Leuven, Belgium; [2]CHU UCL Namur, Pediatrics, Yvoir, Belgium; [3]CHC Montlègia, Pediatrics, Liège, Belgium; [4]AZ Sint-Jan, Pediatrics, Bruges, Belgium; [5]University Hospital of Brussel, Pediatrics, Brussels, Belgium; [6]University Hospital Antwerpen, Pediatrics, Edegem, Belgium; [7]Hôpital Universitaire de Bruxelles (H.U.B), Hôpital Universitaire des Enfants Reine Fabiola (HUDERF), Université libre de Bruxelles (ULB), Brussels, Belgium; [8]UCLouvain, Pediatrics, Brussels, Belgium; [9]CHU Liège, Liège, Belgium; [10]Ziekenhuis Oost-Limburg, Pediatrics, Genk, Belgium; [11]UZ Gent, Gent, Belgium; [12]BELSPEED, Brussels, Belgium

Background & Aim
Prader-Willi Syndrome (PWS) is a rare neurodevelopmental disorder characterized by neonatal hypotonia, feeding difficulties, short stature, behavioural problems, and early-onset hyperphagia leading to progressive obesity. Early diagnosis and a multidisciplinary approach are crucial for managing all these features. This study provides a detailed characterization of the Belgian PWS cohort and evaluates the effectiveness of recombinant human growth hormone (rhGH) therapy.
Patients & Methods
Clinical and auxological data were retrieved from BELGROW, a national database of rhGH-treated patients maintained by BELSPEED (Belux Society for Pediatric Endocrinology and Diabetology), from 1986 until 2021. Baseline characteristics and rhGH treatment outcomes were assessed, including changes in height standard deviation (SD) scores (HSDS).
Results
A total of 123 patients with PWS (50% male) were analysed. Most patients (115/123) were included after 2001. The most common genotype was paternal deletion (53%), followed by maternal uniparental disomy (mUPD) (35%), imprinting disorder (5%), and atypical deletion or translocation (3%). Preterm birth was reported in 21%, and 23% met the criteria for small for gestational age (SGA). Reduced fetal movements were noticed in 79% of pregnancies, and all patients exhibited neonatal hypotonia. Obesity (BMI > 2 SD) was observed in 53%. All patients received rhGH, with the youngest starting at 4.8 months. The median (Q1:Q3) age at therapy initiation was 3.57 years (1.11; 6.54), with a median dose of 0.031 mg/kg/day (0.026:0.035). After two years, HSDS increased by +1.3 SD. Mean weight increased by +0.9 SD, but body mass index (BMI) remained stable (Δ 0.1 SD). Scoliosis was reported in 17% at therapy onset. A subgroup of 52 patients was followed until therapy cessation at a mean age of 15.2 years (12.9–17.5). In this group, rhGH therapy began at a mean age of 7.35 years (4.44–10.69). HSDS improved from -2.2 (-3.1 to -1.1) at initiation to -1.23 (-1.19 to -1.15) at cessation. In addition to multidisciplinary care, patients who started treatment before age 6 ($n = 22$) showed a trend toward a more favorable BMI outcome, with an average SDS decrease of -0.38, compared to a negligible change (+0.02) in those who started later ($P = 0.19$). Patients with a deletion were less frequently obese than those with mUPD.
Conclusions
These findings highlight the effectiveness of rhGH therapy in real-world clinical settings for patients with PWS. Treatment significantly improves height and helps maintain BMI stability, reinforcing the importance of early intervention and long-term management in this population.

New evidence of growth hormone treatment benefit on bone mineralization during transition from paediatric to adult care in a growth hormone deficient french cohort

Clément Bailly[1], Enora Le Roux[2], Michel Polak[3] & Philippe Touraine[1]
[1]AP-HP Pitié-Salpêtrière Hospital - Sorbonne University, Endrocrinology and Reproductive Medicine Department, Paris, France; [2]INSERM, University of Paris, ECEVE UMR 1123, PARIS, France; [3]AP-HP Necker Enfants Malades, Pediatric Endocrinology-Diabetology-gynecology Department, PARIS, France

Introduction
Growth hormone deficiency (GHD) is a rare condition. During childhood (CoGHD), when GHD is confirmed by the hormonal tests, a treatment by growth hormone (GH) is usually introduced. The transition period between paediatric and adult care represents a challenging time. Convincing GHD patients with optimized final stature and their families, to continue GH treatment on such conditions may be complicated. More data need to be collected to better understand the effects of GH treatment during this period, especially for bone health.
Objective
The objective of this study is to describe the bone mass density (BMD) and Zscore evolution during transition period in our CoGHD cohort patients, whether they have received GH treatment in adulthood or not.
Materiel and Methods
We conducted a retrospective study based on our CoGHD patients who had their transition care from 1st January of 1994 to 1st September of 2021. We included all CoGHD patients with a first evaluation (EVAL1) during transition care, and another evaluation (EVAL2) at least 6 months after EVAL1. We described two different populations from our cohort: CoGHD patients continuing GH treatment during more than 6 months between EVAL1 and EVAL 2 (GHT), and CoGHD patients receiving maximum 6 months of GH treatment between the two evaluations (GH0).
Results
162 patients from our 282 CoGHD cohort, were included. In this population, 57 have been treated with GH therapy for 6 months or less (GH0), and 105 continued GH treatment for more than 6 months (GHT). Median follow-up was 5.9 years (3.1-10.8) in GH0 group and 3.6 years (2-6.3) in GHT group. The lumbar spine Z score was -1.61 at EVAL1 and -1.32 at EVAL2 in GH0, and -1.09 at EVAL1 and -0.61 at EVAL2 in GHT ($P = 0.047$). Lumbar spine BMD was 0.90 g/cm^2 at EVAL 1 and 0.93 g/cm^2 at EVAL2 in GH0, and 0.96 g/cm^2 at EVAL1 and 1.01 g/cm^2 at EVAL2 in GHT ($P = 0.17$). The femoral neck Z score was -0.95 at EVAL1 and -0.80 at EVAL 2 in GH0, and -0.87 at EVAL1 and -0.50 at EVAL 2 in GHT ($P = 0.16$). Femoral Neck BMD was 0.81 g/cm^2 at EVAL1 and 0.79 g/cm^2 at EVAL2 in GH0, and 0.89 g/cm^2 at EVAL1 and 0.85 g/cm^2 at EVAL2 in GHT ($P = 0.76$).
Conclusion
Our study provides additional evidence supporting the benefit of GH replacement therapy in bone quality in CoGHD during transition care.

Insulin tolerance test for the diagnosis of adult GH deficiency: definition of BMI-dependent cut-offs using a clinical gold standard

Daniela Cuboni[1], Michela Sibilla[1], Francesca Mocellini[1], Luigi Simone Aversa[1], Emanuele Varaldo[1], Fabio Bioletto[1], Alessandro Maria Berton[1], Nunzia Prencipe[1], Mauro Maccario[1], Ezio Ghigo[1], Silvia Grottoli[1] & Valentina Gasco[1]
[1]Division of Endocrinology, Diabetes, and Metabolism, Department of Medical Science; University of Turin;, Turin, Italy

Background
The diagnosis of adult growth hormone deficiency (GHD) relies on demonstrating a reduced growth hormone (GH) response to stimulation tests. Excess body weight, a condition with increasing prevalence in the general population, is known to blunt GH secretion across all stimulation tests. Consequently, establishing BMI-specific normality cut-offs is essential to ensure accurate interpretation of somatotropic axis function. However, no validated BMI-adjusted cut-offs currently exist for the insulin tolerance test (ITT), the gold standard for GHD diagnosis. This study aimed to define BMI-dependent ITT cut-offs using a clinical criterion as the diagnostic gold standard, addressing key methodological limitations in previous research.
Subjects and Methods
We conducted a retrospective analysis of 105 patients with hypothalamic-pituitary disorders who underwent ITT at our center between January 1, 2021, and September 30, 2024. GHD was defined by the presence of at least three pituitary hormone deficiencies (MPHD), while preserved somatotropic function was established by the absence of other pituitary deficits and an IGF-I SDS ≥ 0. ITT was performed using a standardized protocol. ROC curve analysis was applied to determine optimal BMI-specific cut-off values, defined as those achieving the best sensitivity (SE) and specificity (SP).
Results
The optimal GH cut-off for diagnosing GHD was 2.8 µg/L in normal-weight and overweight subjects (normal-weight: SE 84.6%, SP 97.4%; overweight: SE 100%, SP 92.3%), while for obese individuals, the optimal threshold was lower at 2.1 µg/L (SE 88.2%, SP 87.5%). The area under the ROC curve values were 0.968, 0.957, and 0.897 for normal-weight, overweight, and obese patients, respectively, demonstrating high diagnostic accuracy across BMI categories.
Discussion
This study is the first to establish BMI-specific GH cut-offs for ITT using a clinical definition of GHD as the diagnostic gold standard. The findings reinforce the necessity of applying lower cut-offs in obese individuals to mitigate the risk of overdiagnosis and avoid unnecessary GH replacement therapy. Implementing BMI-adjusted thresholds in clinical practice could enhance diagnostic precision, ensuring that treatment is appropriately targeted to those who will benefit most.

GLP-1 receptor agonists as therapeutic approach to severe obesity in PHP/iPPSD: two case reports

Giulia Del Sindaco[1], Angela Pagnano[1,2], Marie-Agathe Trouvin[3], Giovanna Mantovani[1,2] & Agnès Linglart[3,4,5]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, ERN BOND, ERN for rare endocrine disorders, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]AP-HP, Hôpital Bicêtre Paris-Saclay, Service d'endocrinologie et diabète de l'enfant, Le Kremlin-Bicêtre, France; [4]AP-HP, Centre de Référence des maladies rares du métabolisme du Calcium et du Phosphate, filière OSCAR, ERN BOND, ERN for rare endocrine disorders, Plateforme d'expertise des maladies rares de Paris Saclay, Paris, France; [5]Université Paris Saclay, INSERM U1185, Le Kremlin-Bicêtre, France

Overweight and obesity occur frequently in pseudohypoparathyroidism/iPPSD, especially in children with PHP1A/iPPSD2, who may develop severe early-onset obesity. Both impaired lipolytic response to adrenaline and decreased resting energy expenditure may contribute to weight gain, sometimes accompanied by hyperphagia. Obesity is also reported in PHP1B/iPPSD3 and acrodysostosis. There are no specific treatments for obesity in PHP/iPPSD, except for isolated cases treated with a cannabinoid receptor type 1 antagonist or gastric bypass. To now, no data are available on the use of GLP-1 receptor agonists for weight management in these patients. We aim to describe two patients with PHP/iPPSD, actively followed-up in two tertiary European centers, treated with GLP-1ra for severe obesity. The first patient was diagnosed with PHP1B/iPPSD3 at 15 years of age. He always suffered of overweight, and the mother referred hyperphagia during infancy. At 14 years his BMI was 35 kg/m^2 and dyslipidemia, liver steatosis, insulin resistance and impaired glucose tolerance were also present. At 17 years metformin therapy was introduced to improve his metabolic profile and reduce the gradual weight gain. However, weight continued to raise and at 21 years BMI was 47.6 kg/m^2, thus gastric bypass was proposed. At the same time, we started GLP-1ra therapy with subcutaneous liraglutide, that has been recently shifted to subcutaneous semaglutide. After 23 months at the last follow-up visit, he has lost 14 kg, which represents a 11% decrease in body weight, reaching a BMI of 42.6 kg/m^2. The second patient was diagnosed with PHP1A/iPPSD2 at 3 years of age. She developed early-onset obesity as soon as 4 months of age and had persistent obesity reaching a BMI of 32 kg/m^2 (2.88 SD) at the age of 13 years despite practicing sports regularly and having a healthy lifestyle. At 13 years, the liver US showed steatosis, however the blood metabolic profile was normal; she was then started on liraglutide. Her BMI dropped from 32 to 29.6 kg/m^2 in 8 months, which represents a 7.5% decrease in body weight. She described a significant improvement in satiety. Despite this good response, she stopped treatment on her own and regained weight in the following 6 months, up to a BMI of 30.5 kg/m^2 at the last visit. For both patients, GLP-1 analogs were well tolerated despite nausea and inappetence at the beginning. These two cases suggest that GLP-1ra may represent a promising therapeutic approach for the management of obesity and overweight in PHP/iPPSD patients.

The effects of long-acting growth hormone therapy on serum GH and IGF-i levels and potential safety risks compared to physiological pulsatile growth hormone and daily gh injections

Ashraf Soliman[1], Ahmed Khalil[1], Ahmed Elawwa[1], Nada Alaaraj[1], Noor Hamed[1], Shayma Ahmed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Long-acting growth hormone (LAGH) therapy has revolutionized treatment for growth hormone deficiency (GHD) by enhancing adherence and reducing the frequency of injections compared to daily GH therapy. However, sustained non-pulsatile GH and IGF-I levels, differing from physiological pulsatile secretion, may raise long-term safety and metabolic concerns. This review evaluates the efficacy, serum GH and IGF-I impacts, and safety risks of LAGH therapy relative to daily GH and physiological secretion patterns.
Objectives
1. To assess the clinical efficacy of LAGH in promoting growth and IGF-I regulation.
2. To explore its safety profile, particularly metabolic and proliferative risks, compared to daily GH therapy.
3. To provide quantifiable insights into the percent impact of LAGH therapy across key categories: height SDS improvement, IGF-I level changes, and safety.
Methods
A comprehensive literature review of studies published between 2006 and 2025 was conducted. Data on height SDS improvements, IGF-I level changes, and reported safety events were extracted and analyzed. Studies were categorized and impact percentages were calculated based on clinical outcomes and safety metrics.
Results
• Efficacy:
LAGH therapy demonstrated an average 12% improvement in height SDS, with efficacy comparable to daily GH therapy (Miller *et al*., 2020; Kang *et al*., 2024).
• IGF-I Monitoring:
Sustained IGF-I levels increased by 23% on average, highlighting significant metabolic activity, but requiring careful monitoring to mitigate risks of excessive exposure (Bidlingmaier & Schilbach, 2021; van Dijk *et al*., 2006).
• Safety Concerns:
Safety events, inversely scored for impact, were relatively low at 4 per 100 patients, with no severe adverse outcomes reported in recent trials (Savendahl *et al*., 2022; Bruzzi *et al*., 2023).
• Patient Adherence:
LAGH improved patient adherence and accessibility, reducing injection burden and enhancing treatment satisfaction (Steiner *et al*., 2023; Boguszewski *et al*., 2024).
• Long-Term Needs:
Personalized dosing and regular IGF-I monitoring are essential to mimic physiological GH secretion (Clemmons, 2007; Bruzzi *et al*., 2023).
Discussion
While LAGH therapy offers significant clinical benefits, sustained non-pulsatile GH and IGF-I levels deviate from natural physiology, posing potential risks such as glucose intolerance and proliferative disorders. Percent impact analysis reveals notable gains in height and IGF-I levels, with minimal safety concerns, affirming the therapy's efficacy. However, long-term safety monitoring remains essential.
Conclusion
LAGH therapy is a viable alternative to daily injections, delivering notable improvements in growth and IGF-I levels with minimal safety concerns. Optimized dosing and ongoing research are critical to aligning LAGH therapy with physiological GH dynamics.

Positive impact of healthcare professionals' interaction with a digital health platform on patient adherence to recombinant human growth hormone therapy

Antonio de Arriba[1], Paula van Dommelen[2], Lilian Arnaud[3] & Ekaterina Koledova[4]
[1]Hospital Universitario Materno-Infantil Miguel Servet, Zaragoza, Spain; [2]The Netherlands Organization for Applied Scientific Research TNO, Leiden, Netherlands; [3]Devices and Connected Solutions Engineering, Global Healthcare Operations, Ares Trading S.A. (an affiliate of Merck KGaA, Darmstadt, Germany), Eysins, Switzerland; [4]Global Medical Affairs Cardiometabolic and Endocrinology, Merck Healthcare KGaA, Darmstadt, Germany

Background
The Growzen® Connect digital ecosystem has been developed to support timely treatment optimisation for patients on recombinant human growth hormone (r-hGH) therapy. This ecosystem includes electronic injection devices with adherence data transmitters and a platform for healthcare professionals (HCPs) to monitor real-time patient adherence. This study aimed to investigate whether HCPs' interaction with this platform influences adherence to r-hGH therapy in patients from Spain.
Methods
Adherence data (optimal [≥85%] vs suboptimal [<85%]) at the patient level and three clinic-level metrics were extracted from the platform between July 2023 and June 2024. Patients from Spain aged <18 years were selected. The first metric for platform engagement was frequency of use, which is the number of clinic connections by number of patients, stratified by ≥1 (at least one connection/patient/-year), >0-<1 (less than one connection/patient/year), and 0 (no connection). The second metric for platform engagement was data entry, which is the number of growth data entries by the number of patients, stratified by ≥1 (at least one measurement/patient/year), >0-<1 (less than one measurement/patient/year), and 0 (no measurement). The metric for treatment engagement is defined as the number of dose changes by number of patients, stratified by ≥2 (at least two dose changes/patient/year), ≥1-<2 (less than two and greater or equal to one dose changes/patient/year), and <1 (less than one dose change/patient/year). Multi-level logistic regression analyses were performed with adherence as an outcome and metrics as input adjusted for standardised age at treatment initiation and standardised time on treatment.
Results
Adherence data were obtained from 3,980 patients in 186 clinics. In July 2023, the mean age at treatment initiation was 10.7 years and the mean time on treatment was 21 months as of July 2023, the start of the extraction period. The proportions of patients with optimal adherence were 76% (n = 883/1,161), 79% (n = 1,998/2,542; P = 0.13), and 88% (n = 245/277; P <0.001) in clinics with no (n = 92), >0-<1 (n = 65), and ≥1 (n = 29) connections/patient/year, respectively. The proportions were 78% (n = 2,551/3,270), 80% (n = 542/675; P = 0.86), and 94% (n = 33/35; P = 0.009) in clinics with no (n = 173), >0-<1 (n = 12), and ≥1 (n = 1) measurements/patient/year. Furthermore, the proportions were 71% (161/228), 78% (2,207/2,833; P = 0.62), and 82% (758/919; P = 0.25) in clinics with <1 (n = 27), ≥1-<2 (n = 111), and ≥2 (n = 48) dose changes/patient/year, respectively.
Conclusions
Our research revealed that HCPs' interaction with the digital adherence monitoring platform Growzen® Connect positively influences patient adherence to r-hGH therapy in Spain.

Results of treatment with recombinant human growth hormone (rhGH) in patients with noonan syndrome. albanian experience

Agim Gjikopulli[1], Laurant Kollcaku[1], Sonila Tomori[1], Era Kurti[1] & Anila Babameto[2]
[1]Pediatric Endocrinology Unit, Department of Pediatric, University Hospital Center "Mother Teresa", Albania, Tirana, Albania; [2]Genetic Unit, Department of Pediatric, University Hospital Centre "Mother Teresa," Albania, Department of Pediatric, Tirana, Albania

Introduction
Noonan syndrome (NS) is a relatively common disease with an incidence estimated to be from 1 in 1000 to 1 in 2500 live births. It is a genetically heterogeneous autosomal dominant malformation syndrome. Growth impairment is a common manifestation of NS. In a few studies, recombinant human GH (rhGH) treatment has been shown to increase growth and adult height (AH).
Objectives
To evaluate the effect of rhGH treatment in children with NS and to identify the best indicators of the outcome of this treatment.
Patients and Methods
This is a 24-year-long, monocentric cohort study. Children with NS were followed up from January 2000 to December 2024 in the Pediatric Endocrine Unit, Department of Pediatrics, University Hospital Centre "Mother Teresa", Albania. Patients with NS who were treated with growth hormone until near adult height (NAH) were included in the analysis of this study. We evaluated growth indicators (especially height) before treatment (at the time of starting treatment), during the treatment (evaluating these indicators for each year of treatment), and after the rhGH treatment for patients who completed treatment with rhGH. Growth indicator data were processed using Anthro-plus software, and statistical analysis was performed using SPSS.
Results
During the period mentioned above, 25 patients with NS have been treated with rhGH. There were 19 (73,08%) males and 7 (26,92%) females. The age at which rhGH treatment started was 10,08 ± 4,12 years. The Bone age was 7,38 ± 3,54 years. HAZ at the beginning of therapy was -3,65 ± 1.17 z-score. Sixteen out of 26 (61,54%) have completed the treatment after the meantime treatment duration of

5,18 ± 2.18 years with the mean dose of rhGH at 0.24 IU/week. Their height changed from -3,81 ± 0,83 z-score to -2,56 ± 1,55 z-core, gaining about 1,25 ± 1,43 z-score (p-value 0,003). Despite the late start of treatment, significant height gains were achieved, with a minority (37.5%) reaching the target height range. The NAH was found to correlate well with the adult predicted height, as well as the HAZ score at the start of treatment, the age at the beginning of treatment, the change in the HAZ score during puberty, the duration of GH treatment, and the bone age at the start of treatment.

Conclusions

Our study results provide valuable insights about the effectiveness of rhGH treatment in patients with NS, enlightening us on the factors influencing their height outcomes better.

Growh patterns and genotype-phenotype correlations in tricho-rhino-phalangeal syndrome type i: insights from a korean cohort

A Young Park[1] & Jung Min Ko[1]

[1]Seoul National University Hospital, Pediatrics, Seoul, South Korea

Background/Objectives

Tricho-rhino-phalangeal syndrome, type I (TRPS I, OMIM#190350) is a rare autosomal dominant disorder characterized by distinctive craniofacial features, skeletal abnormality, and ectodermal dysplasia. Due to variable expressivity, TRPS I often remains undiagnosed, leading to unclear prevalence and a lack of large-scale cohort studies. This study aims to delineate the clinical features and genotypes of TRPS I patients in Korea.

Methods

We retrospectively reviewed the medical records of 20 genetically confirmed TRPS I patients (8 males, 12 females) from 20 families. Data collected included demographic information, clinical profiles (growth, craniofacial features, ectodermal dysplasia, skeletal abnormalities), radiologic findings, and treatment history. Genetic diagnoses were confirmed using Sanger sequencing, MLPA, qPCR, or gene panel sequencing.

Results

The median age at diagnosis is 9.0 years old (range: 20 months to 35.1 years). Short stature (35%) was the most common presenting symptom, followed by hypotrichosis (20%) and finger deformity (15%). Almost all patients (95%) had heights below the 50th percentile, with a median height of -1.25 SDS at diagnosis. Four patients (21%) had heights below -2.0 SDS. After 12 years of age, height SDS significantly decreased, accompanied by accelerated bone age, suggesting impaired pubertal growth spurt. Patients aged 12 years and older had significantly lower height SDS than those under 12 ($P = 0.016$). Clinical features included sparse hair (100%), sparse eyebrows (83%), and a pear-shaped nose (100%). Skeletal surveys showed cone-shaped epiphyses in all patients. Four patients (20%) had skeletal abnormalities, including hip dysplasia, with two undergoing hip surgery and one requiring femur osteotomy. Fourteen patients (70%) have been treated with Minoxidil for hypotrichosis, with 50% showing improvement. Genetic analysis revealed diverse pathogenic variants in TRPS1, with 4 (20%) patients having exonic deletions. All 16 sequence variants were private. Variants were distributed across exons 3 to 7, with 9 (45%) being novel. Thirteen (65%) patients had frameshift or nonsense variant. For hand deformities, the exon 6 missense variant was associated with severe hand deformities, while other genotypes exhibited variable severity.

Conclusion

TRPS I can present with short stature, alopecia, and early-onset skeletal dysplasia in pediatric patients, with impaired pubertal growth spurt and accelerated bone age. There were no mutational hotspots, and hand deformities were most severe in patients with exon 6 missense variants. Copy number variation analysis is essential for identifying the genetic etiology in patients without sequence alterations.

Noonan syndrome: a retrospective observational study from a paediatric endocrinology unit at a portuguese tertiary hospital

Nuno Jesus[1,2], Henrique Alexandrino[2], Catarina Tavares[3], Mariana Viegas[4], Marta Martins[5], Inês Rua[5], Isabel Dinis[5], Joana Serra-Caetano[5], Rita Cardoso[5] & Alice Mirante[5]

[1]i3S, University of Porto, Cancer Signalling & Metabolism, Porto, Portugal; [2]Unidade Local de Saúde de Gaia e Espinho, Endocrinology Department, Vila Nova de Gaia, Portugal; [3]Unidade Local de Saúde Viseu Dão-Lafões, Department of Paediatrics, Viseu, Portugal; [4]Unidade Local de Saúde do Oeste, Department of Paediatrics, Caldas da Rainha, Portugal; [5]Unidade Local de Saúde de Coimbra, Hospital of Paediatrics, Coimbra, Portugal

Introduction

Noonan Syndrome (NS) is a genetic disorder characterized by typical facial dysmorphisms, short stature, and congenital heart defects. Several genes have been implicated; approximately 50% of affected individuals present alterations in the *PTPN11* gene, involved in the RAS/MAPK pathway.

Aim

To characterize NS patients followed in the Paediatric Endocrinology Unit in a tertiary hospital from the centre region of Portugal.

Methods

Patients diagnosed with NS and followed in the pediatric endocrinology unit between 2009 and 2024 were identified, and demographic and clinical data were collected.

Results

Eighteen patients diagnosed with NS were identified, of whom 12 (66.7%) were boys. The main reason for referral to the Paediatric Endocrinology Unit was short stature (77.8%), followed by poor weight gain (11.1%) and delayed puberty (11.1%). At the first consultation, patients had a median age of 8.3 years (IQR: 3.7-12.3), although their median age at diagnosis was 3.5 years (IQR: 1.7-10.2). Patients presented with typical facial features (88.9%), cardiac defects (61.1%), stature below P3 (77.8%), *pectus excavatum* (27.8%), developmental delay (44.4%), lymphatic defects (22.2%), and confirmed family history (11.1%), and suspected family history (5.6%). Cryptorchidism was present in 41.7% of boys. Molecular studies were available in 15 cases, identifying mutations in PTPN11 (66.7%), SOS1 (13.3%), BRAF (6.7%), LZTR1 (6.7%), and NF1 (6.7%). The median height z-score at the first consultation was -2.6 (IQR: 1,5), confirming the short stature in 14 patients (77.8%). The median z-score for target height was -0.3 (IQR: 0.7). The final height was available for 7 patients, corresponding to a median height z-score of -1.6 (IQR: 1.7) and a median difference of -1.9 (IQR: 2.6) compared to the target height z-score. At follow-up, only 3 patients presented growth hormone deficiency, receiving an average dose of recombinant human growth hormone (rhGH) 0.029 mg/kg/day (min. 0.021; max. 0.034) for 52 months (min. 16; max. 88). At the last evaluation, 7 (38.9%) patients were prepubertal, and 6 (33.3%) exhibited delayed puberty. Twelve (66,7%) patients exhibited varying neurodevelopmental delays or learning difficulties.

Discussion

The multisystemic involvement of NS requires a multidisciplinary team approach. Paediatric Endocrinology plays a key role in addressing short stature and pubertal development. Despite the approval of rhGH for the treatment of NS in Europe, the conditions for initiating therapy depend on the regulations of each member state. The rhGH improves final height, mainly when initiated early and maintained for a more extended period before the onset of puberty.

An atypical case of silver-russel syndrome linked to a novel variant in HMGA2 gene

Nataliya Volevodz[1,2], Kristina Kokoreva[1,2], Zinaida Zyuzikova[1] & Kseniya Zabudskaya[1]

[1]National Medical Research Center for Endocrinology, Moscow, Russian Federation; [2]Moscow Regional Clinical Research Institute named after M.F. Vladimirsky (MONIKI), Moscow, Russian Federation

Introduction

Silver-Russell syndrome (SRS) is a clinically and genetically heterogeneous disorder characterized by short stature, a typical facial phenotype, and body asymmetry. Molecular genetic abnormalities, such as maternal uniparental disomy of chromosome 7 and hypomethylation of the 11p15 region, are commonly observed in SRS, approximately 40% of patients still lack a confirmed genetic diagnosis. Identifying the underlying molecular cause is essential for accurate diagnosis, effective treatment, and genetic counseling for affected families.

Materials and Methods

A 7-year-old girl was referred due to concerns of growth and weight delay. She was born from second pregnancy complicated by intrauterine growth restriction and delivered by cesarean section at 39 weeks. Birth weight 1820 g (SDS: -3.3), birth length 44 cm (SDS: -4.34), Apgar score 6/8. The family history was non-contributory: maternal height 168 cm, paternal height 170 cm, target height of 160.5 cm (SDS: 0.08). There were no reported comorbidities.

Results

At the time of evaluation, the girl had a proportional physique. Notable dysmorphic features included a wide protruding forehead, clinodactyly of the fifth finger, and

abnormal dental development. Height 103.0 cm (SDS: -3.2), weight 13.8 kg, BMI SDS -1.9. Over the past 18 months, she had grown 6.5 cm. During examination, bone age was delayed by 1 year, and IGF-1 was measured at 103 ng/ml. No deficiency of other pituitary tropic hormones was detected. To investigate maternal uniparental disomy of chromosome 7, microsatellite analysis was performed on critical loci at 7q33-34 (D7S2202, D7S91824) and 7p12.1-12.3 (D7S2422, D7S2519). Additionally, multilocus methylation-sensitive PCR was used to assess allele-specific methylation in the 11p15 region, including the H19/IGF2 imprinting control region. The analyses excluded characteristic molecular genetic defects of SRS, including maternal uniparental disomy of chromosome 7 and hypomethylation of the 11p15 region. Given the negative results, the patient and her parents underwent whole-exome sequencing of peripheral blood lymphocyte DNA in a "trio" format. A previously undescribed heterozygous *de novo* variant was identified in the *HMGA2* gene (NC_000012.2:g.65825359G>A, NM_003483.6: c.89G>A, p.(Gly30Asp)), associated with SRS type 5 (OMIM: 618908). Segregation analysis in the family confirmed the variant by Sanger sequencing.

Conclusion

The use of advanced genetic testing methods, including whole-genome and whole-exome sequencing, significantly improves diagnostic accuracy in patients with suspected SRS. The identification of a novel monogenic cause in this patient facilitated the initiation of somatotropic treatment and enabled comprehensive genetic counseling for the family.

JOINT2273

A single center real world experience with vosoritide for the treatment of children with achondroplasia

Ana Paula Bordallo[1], Tatiana Magalhães[2], Henrique Botti[2], Dafne Horovitz[2], Juan Llerena Jr[2] & Paulo Collett-Solberg[1]
[1]Universidade do Estado do Rio de Janeiro, UERJ, Division of Endocrinology, Department of internal Medicine, Rio de Janeiro, Brazil; [2]Instituto Fernandes Figueira - Fiocruz, Rio de Janeiro, Brazil

Introduction

Achondroplasia is the most common skeletal dysplasia with severe short stature. It is characterized by gain-of-function variants in the *FGFR3* gene. In Brazil, vosoritide was approved in 2021 for ACH children ages 2 years and older, then in 2023 it was approved for children ages 6 months and older.

Objective

to assess the real-world response of children with achondroplasia to Vosoritide.

Methods

Thirty-two children with genetic confirmed achondroplasia initiated treatment with Vosoritide. Height and weight were measured. Changes in height SDS based on WHO growth curves (WHO) or based on achondroplasia specific growth curves (ACH) were assessed after 6 months ($n = 21$) and after 1 year ($n = 14$) of treatment. Adverse events were assessed in all 32 children.

Results

The mean age at start of treatment was 6.1 years. Data for the whole group: Twelve females completed 6 months of treatment and 9 completed 12 months. Even though there was an increment in height SDS after 6 or 12 months, this change was not statistically different. On the other hand, despite having fewer male individuals (9 completed 6 months and 6 completed 12 months) there was a significant difference in height SDS. Safety: Eight patients presented hypertricosis (7 females) that was noticed after a mean duration of treatment of 4.37 ± 1.99 months and a range of 3 and 8 months. Three patients reported local pain at injection site.

Discussion

There is an overall increment in height of children with Achondroplasia in response to the treatment with Vosoritide. Changes in height SDS can be better observed using specific standards for individuals with achondroplasia. The response was better in males. One possible explanation is that some children do not respond robustly to the treatment and in our cohort, we had two, both females.

All Patients (Height)	WHO		ACH	
	6mo	12mo	6mo	12mo
Basal	-4.48 (±0,95)	-4.59 (±0.79)	+0,57(±0,99)	+0,40(±0,84)
After Treatment	-4.36 (±0.95)	-4.39 (±0.8)	+0.77 (±1,05)	+0,71(±0,85)
	(*P* = 0,16)	**(*P* = 0,02)**	**(*P* = 0,002)**	**(*P* = 0,003)**

Height	WHO				ACH			
	Male		Female		Male		Female	
	6mo	12mo	6mo	12mo	6mo	12mo	6mo	12mo
Basal	-3.84 (±0.91)	-4.07 (±0.70)	-4.88 (±0.72)	-4.94 (±0.66)	1,25 (±1.05)	1.01 (±0.80)	0.10 (±0.71)	-0.001 (±0.60)
After treatment	-3.67 (±0.80) **(*P*=0,034)**	-3.81 (±0.65) **(*P*=0.001)**	-4.87 (±0.70)	-4.76 (±0.67)	1,55 (±0.96) **(*P*=0,004)**	1.4 (±0.80) **(*P*=0.0006)**	0.198 (±0.67)	0.260 (±0.53)

Conclusion

Treatment was well tolerated. The difference in SDS based on Achondroplasia standards is more significant than based on WHO standards.

Sex steroid priming prior to growth hormone stimulation testing in peripubertal adolescents with short stature?

Sofia Leka-Emiri[1], Eirini Dikaiakou[1], Costas Mihas[2], Katerina Papadopoulou[1], Ioanna Kosteria[1], Maria Kafetzi[3] & Elpis Vlachopapadopoulou[1]
[1]Department of Endocrinology-Growth and Development, Children's Hosp. "P.& A. Kyriakou", Athens, Greece; [2]General Hospital of Kimi, Evia, Greece; [3]Dept Biochemistry-Hormones Laboratory Children's Hosp. "P.& A. Kyriakou", Athens, Greece

Introduction

Growth hormone stimulation testing (GHST) is recommended to diagnose growth hormone deficiency (GHD) in children. Sex steroids impact on anterior pituitary function, therefore, the efficacy of GHST in peripubertal children, where endogenous sex steroid levels are low is challenging. Sex steroid priming before GHST has been proposed to improve test efficacy in these children, however clear evidence to support its use in clinical practice is limited.

Methods

A total of 141 children with short stature (height <3rd %) (71boys) (Tanner 1, 43.6%*/*), mean age 12±2.3years, were evaluated for growth hormone deficiency upon a 2 year period (2020 -2022). Standard GHST with prior steroid priming ($n=$ 76, 53.9%, mean age 12.5±2years) were compared to a group without prior steroid priming ($n = 65$, 46.1%, mean age 11.7±2.4years) (p=NS). For priming, sex steroids were delivered; testosterone enanthate 100mg IM 5-7 days before GHST for boys and estradiol valerate 1-2mg PO 3 days before GHST (glucagon or clonidine) for girls.

Results

Median GH peak max was 7.1ng/ml (IQR: 6.2) without vs. 7.7 (IQR: 8.0) with prior steroid priming (p=NS). Median E2 levels were 40.4 pg/ml (IQR: 77.1) before vs 68.9pg/ml (IQR: 54.3) after priming ($P = 0.013$); median testosterone levels were 3.2ng/ml (IQR: 5.8) vs 5.7ng/ml (IQR: 6.9) respectively (p=NS). Prepubertal children (Tanner 1) had significantly higher GH response after priming (10.1 vs 8.7 ng/ml, p:0.011) as opposed to pubertal Tanner 2 (9.1 vs 9.3 ng/ml) (p:0.097). Females demonstrated significantly higher median E2 levels after priming (70.6 vs 40.4 pg/ml) (p:0.013) as compared to males with respect to median levels of testosterone (5.7 vs 3.2 ng/ml) (p:0.056).

Conclusion

In our cohort of peripubertal adolescents with short stature sex steroid priming prior to growth hormone stimulation testing failed to reveal statistically significant difference in growth hormone secretion.

Lamb-Shaffer syndrome as a rare cause of short stature

Valentina Mancioppi[1], marika nacci[1], valentina lupieri[1], riccardo battiston[1], Paolo Cavarzere[1], Anita Morandi[1] & Claudio Maffeis[1]
[1]Section of Pediatric Diabetes and Metabolism, Department of Surgery, Dentistry, Pediatrics and Gynecology, University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy

Background

Lamb-Shaffer syndrome (LAMSHF) is an extremely rare genetic disorder due to *SOX5* gene mutation, characterized by global developmental delay, intellectual disability, skeletal anomalies and typical facial features.

Case report

An 11-month-old boy came to our attention for poor growth. His weigh was 6120 g (-3.95 SD, WHO), length 70 cm (-2.10 SD, WHO) and CC 33.5 cm (-1.24 SD, WHO). Frontal bossing, reduced subcutaneous fat with dystrophic appearance and cervical axial tone inadequate for age were observed. Past medical history: born by *in vitro* fertilization (FIVET) at 37 weeks of gestational age after a pregnancy complicated by

gestational diabetes, treated with insulin. The birth weight was 2400 g (-1.64 SDS), the length was 47 cm (-1.03 SDS), and the cranial circumference (CC) was 33.5 cm (-0.40 SDS). Ostium secundum atrial septal defect was found after the birth, no alterations at the neonatal cranial ultrasound, and the glycemic control was always adequate. After the birth the patient was admitted to the hospital frequently: at the age of 5 months due to respiratory syncytial virus bronchiolitis, at 7 months for fever and feeding difficulties, at 9 months due to Cytomegalovirus and B-influenza virus infection. No alterations were found at the abdominal and heart ultrasound. After the weaning the boy showed bottle feeding difficulties with daily vomiting episodes and a global developmental delay. During the subsequent hospitalization due to urinary infection, selective immunoglobulin A deficiency was found, and the brain Magnetic Resonance Imaging (MRI), performed due to the worsening developmental delay, showed a ventricular dilatation, with global subatrophy, without acute event signs. After our first evaluation, due to his worsening short stature (SS) associated by neuropsychiatric impairment, a new laboratory assessment was performed: growth hormone deficiency and celiac disorder were ruled out, and no food allergies were found. Array CGH showed 12p12.1 de novo deletion, involving *SOX5* gene.
Conclusions
LAMSHF is a rare condition with normal birth parameters and growth impairment can be developed during the first years of life. In children with SS, once the main causes of their growth deficiency are ruled out, genetic evaluation has to be considered for the differential diagnosis. In this context, due to SS associated with neurodevelopmental delay, we preferred to perform an Array CGH that permitted the diagnosis. There is no specific treatment for LAMSHF but a comprehensive multidisciplinary care model is required for these patients.

Identification of a novel heterozygous variant of the aggrecan gene in a family with idiopathic short stature and accelerated bone maturation: treatments and challenges

Alessio Rossi[1,2], Laura Corbelli[1,2], Matteo Pontone[1,2], Eugenio Trinati[1,2], Annarita Giliberti[3], Giovanna Traficante[3] & Stefano Stagi[1,2]
[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Diabetology and Endocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy; [3]Division of Medical Genetics, Neuroscience and Medical Genetics Department, Meyer Children's Hospital IRCCS, Florence, Italy

Introduction
The proteoglycan aggrecan, transcripted by *ACAN* gene, is the most abundant non-collagenous protein in the extracellular matrix in cartilaginous tissue. Variants in *ACAN* result in a broad phenotypic spectrum of skeletal dysplasias and various undefined short stature syndromes associated with accelerated bone maturation. We present the case of two brothers with short stature, treated with different growth-promoting therapies and later being diagnosed with *ACAN* variant.
Case report
Patient 1 was referred to our Endocrinology Unit for short stature and GH deficiency, confirmed with two stimulation tests. No significant medical history. He was born appropriate for gestational age; familiarity for short stature in mother and into the maternal line. He was treated with GH therapy from 5 years of age, with height improvement from < -2 SDS up to 10° centile. An anticipated puberty with rapid progression negatively affected patient final height, <-3 SDS. Extensive blood examinations, ACTH test, new CNS MRI and *SHOX*-gene analysis were normal. Patient 2, brother of patient 1, was referred at 5 years of age for short stature. GH deficiency was ruled out with GH-stimulation tests. Radiological evaluation showed advanced bone aged of 1.5 years. Adrenal axis evaluation was normal. At 9 years old he was diagnosed Central Precocious Puberty and was treated with GnRH agonist, Decapeptyl 3.75 mg/28 days. The therapy was suspended at the age of 12, with a skeletal age of 13. After 6 months, bone age advanced 1 more year, therefore, taking also into account the family history, he started aromatase-inhibitor therapy, anastrozole 1 mg/day, in order to slow down growth plate fusion. After pubertal spurt he was -2.5 SDS for height and genetic analysis were performed. Exome sequencing showed the heterozygous variant c.6620C>A (p.(Ser2207*)) in *ACAN* gene, inherited by his mother and presents also in his brother. This variant is not descripted in literature and in the Human Gene Mutation Database yet and it was classified as probably pathogenetic (ACMG).
Discussion
Genetic evaluation, with the widespread use of next-generation sequencing technology, has been demonstrated as an important tool to elucidate the causes of growth disorders. Patient 1 partially responded to GH treatment, as already reported in the literature. Treatment with GnRH analogue and aromatase inhibitor, carried out in patient 2, did not lead to better results and not effectively improve the final height. Bone age pathological progression due to aggrecan variant is still an open challenge.

Differences in age at treatment start of recombinant human growth hormone therapy among european countries

Paula van Dommelen[1], Chiara Centonze[2], Senthil Senniappan[3], Petur Juliusson[4,5,6], Lilian Arnaud[7] & Ekaterina Koledova[8]
[1]The Netherlands Organisation for Applied Scientific Research TNO, Leiden, Netherlands; [2]Medical Affair, Merck Serono SpA (an affiliate of Merck KGaA, Darmstadt, Germany), Rome, Italy; [3]Consultant Paediatric Endocrinologist, Alder Hey Children's Hospital and Honorary Associate Professor, University of Liverpool, Liverpool, United Kingdom; [4]Children and Youth Clinic, Haukeland University Hospital, Bergen, Norway; [5]Department of Health Registry Research and Development, National Institute of Public Health, Bergen, Norway; [6]Department of Clinical Science, University of Bergen, Bergen, Norway; [7]Devices and Connected Solutions Engineering, Global Healthcare Operations, Ares Trading S.A. (an affiliate of Merck KGaA, Darmstadt, Germany), Eysins, Switzerland; [8]Global Medical Affairs, Cardiometabolic and Endocrinology, Merck Healthcare KGaA, Darmstadt, Germany

Background
Early initiation of recombinant human growth hormone (r-hGH) therapy in patients with growth hormone deficiency (GHD) is important as it can improve growth-related outcomes.
Objective
This study aimed to evaluate the age at treatment start in children and adolescents with GHD treated with r-hGH therapy (Saizen®, Merck KGaA, Darmstadt, Germany) among European countries.
Methods
Data of age at treatment start of patients aged <18 years with GHD from European countries were extracted from the Growzen™ Connect digital ecosystem. However, whether patients were previously treated with r-hGH from another company was unknown (non-naive).
Results
Data on age at treatment start was available for 10,150 patients from 15 European countries. The median age at treatment start was <8 years in Sweden and Finland; 9 years in the Czech Republic, Austria, Germany, and United Kingdom; 10 years in Hungary, Slovakia, France, Romania, and Spain; and >10 years in Switzerland, Ireland, Italy, and Serbia.
Conclusions
Although these data include non-naive patients, our findings show variations in the age at treatment start across different European countries. The data suggests a delayed start of r-hGH treatment across most European countries, which has potential implications for the final height outcome. The differences may be explained by the use of different country-specific guidelines for the early detection of growth disorders and their degree of implementation, the number and timing of healthcare visits and other healthcare practices. These results underscore the importance of harmonising guidelines and strategies for early detection of growth disorders across Europe to ensure optimal patient outcomes.

(Un)satisfactory effectiveness of whole-exome sequencing in detecting genetic causes of differential sexual development in 46,XY patients

Ewa Błaszczyk[1,2], Małgorzata Więcek[1], Aleksandra Jezela-Stanek[3], Grzegorz Kudela[4], Tomasz Koszutski[4], Karolina Kowalczyk[5], Jagoda Sikora[1], Agnieszka Bielska-Brodziak[6] & Aneta Gawlik-Starzyk[1]
[1]Departments of Pediatrics and Pediatric Endocrinology, Faculty of Medical Sciences in Katowice, Medical University of Silesia, Katowice, Poland; [2]Medical University of Silesia, Katowice, Poland, Departments of Pediatrics and Pediatric Endocrinology, Faculty of Medical Sciences in Katowice, Katowice, Poland; [3]Department of Genetics and Clinical Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland; [4]Department of Pediatric Surgery and Urology, Medical University of

Silesia, Katowice, Poland; [5]Department of Endocrinological Gynecology, Medical University of Silesia, Katowice, Poland; [6]Faculty of Law and Administration, University of Silesia, Katowice, Poland

Introduction
Differential sexual development (DSD) with 46,XY is a group of rare congenital disorders of the structure and function of the urogenital system resulting from abnormal testicular development or disorders of androgens action. Published data shows that despite the increasingly frequent genetic diagnostics, the causes remain unclear in more than half of cases; with only 34-46% confirmed by molecular testing.
Aim of the study
An attempt to determine the genetic causes of DSD in patients with karyotype 46,XY using the whole-exome sequencing (WES) method.
Patients&Methods
In a consecutive group of 36 children diagnosed in our center as 46,XY DSD (aged 2.4 – 17.9, median age 5.13), 29 raised as boys and 7 raised as girls, with a detailed description of the clinical and biochemical profile, WES was performed.
Results
Pathogenic, potentially pathogenic and variants of uncertain clinical significance (VUS) are presented in the table. No variants that could be related to DSD symptoms were found in the remaining children.
Conclusions
Currently WES is the state of the art method in terms of the quantity of covered genes, nevertheless genetic cause of DSD could still only be identified in less than half of 46,XY DSD patients, for whom the "glass is half full". It is recommended to reexamine the WES results every 12 months and to verify the status of the identified VUS in the biological parents of the patients.

Mixed segmental uniparental disomy of chromosome 15q11-q1 coexists with homozygous variant in GNB5 gene in child with Prader-Willi and Lodder-Merla syndrome

Beata Wikiera[1], Tomasz Marczyk[2], Maria Libura[3], Magdalena Goralska[4], Agnieszka Pollak[5], Rafał Płoski[4] & Robert Śmigiel[6]
[1]Wroclaw Medical University, Department of Pediatrics, Endocrinology, Diabetology and Metabolic Diseases, Wrocław, Poland; [2]Lower Silesian Specialist Hospital - Emergency Medicine Center, Department of Pediatric Neurology, Wrocław, Poland; [3]Medical University of Gdansk, Department of Public Health and Social Medicine, Gdansk, Poland; [4]Medical University of Warsaw, Department of Endocrinology, Warsaw, Poland; [5]Medical University of Warsaw, Department of Medical Genetics, Warsaw, Poland; [1]Wroclaw Medical University, Department of Pediatrics, Endocrinology, Diabetology and Metabolic Diseases, Wrocław, Poland

Background
Uniparental disomy presents two primary developmental risks: inheriting a recessive trait or occurrence of an imprinting disorder. Occasionally, these risks may coexist in a single patient, leading to a rare comorbidity. Managing comorbidities associated with rare diseases presents unique clinical challenges. The aim of this study is to present the case of a boy who was ultimately diagnosed with two rare diseases: Prader-Willi syndrome associated with maternal UPD15 and autosomal recessive Lodder-Merl syndrome associated with a new pathogenic variant of the GNB5 gene.
Case report
A fourteen-month-old boy of young, healthy parents, born by cesarean section in the 38th week of pregnancy with a birth weight of 2110 g, Apgar 7 - 10 points. Bilateral cryptorchidism, hypotonia, weak sucking reflex, apneas, congenital pneumonia, and respiratory failure were found. Treated in the Neonatal Intensive Care Unit, fed through a nasogastric tube. In the fourth month of life, semiological seizures consistent with infantile spasms appeared. The attacks occurred daily in 4-6 series lasting approximately 3 minutes. Neurological examination at the age of 4 months revealed microcephaly (OFC 38.5 cm, below the 3rd percentile), bilateral ptosis, open mouth, poor facial expressions, bilateral horizontal nystagmus, without fixation, profound global hypotonia, poor motor skills. The EEG recording was abnormal and drug-resistant epilepsy was diagnosed. During further follow-up, the patient showed no developmental progress. Genetic testing identified an abnormal DNA methylation pattern in the critical PWS 15q11-q13 region. Microsatellite polymorphism analysis in the 15q region in the proband and both parents confirmed maternal uniparental disomy of chromosome 15. Due to the patient's clinical picture, trio-WES and mitochondrial genome analysis were performed. A homozygous variant of the GNB5 gene was detected in the isodisomy region on chromosome 15. WES analysis of the mother's sample showed that she was a heterozygous carrier.
Conclusions
Co-occurence of PWS and some unexpected or severe phenotype should always raise suspicion of comorbid genetic disease attributed to genes located in Prader-Willi syndrome-associated critical region of chromosome 15q. Epileptic encephalophaty with cardiac arrythmia should implicate prompt cardiologist and genetic care. Presented case provides further support for uniparental disomy as an unexpected cause of Lodder-Merla syndrome. This implicates the importance of comprehensive genetic testing including parental testing and familial cascade testing to learn about recurrence risk.

The impact of growth hormone treatment on physical performance in adult patients with severe growth hormone deficiency - preliminary results

Jagoda Alicja Rogowska[1,2], Izabella Czajka-Oraniec[2], Maria Stelmachowska-Banaś[2] & Wojciech Zgliczyński[2]
[1]Doctoral School of Translational Medicine, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland

Introduction
Growth hormone (GH) influences body composition, appearance, and physical performance by stimulating muscle tissue growth while promoting lipolysis. However, it is not clear if recombinant human growth hormone (rhGH) replacement impacts physical fitness of adult patients with severe growth hormone deficiency (GHD).

Aim
To assess the impact of a 6-month rhGH supplementation on the physical fitness of patients with GHD.
Patients and methods
Seventeen adult patients with GHD were enrolled (9 females, 8 males). The mean age of patients was 40.4 ± 12 years. Physical fitness was assessed using exercise tests such as 6-minute walk test, 30-second chair stand test, up-and-go test, handgrip strength test baseline and after 6 months of rhGH treatment.
Results
All patients normalized IGF-1 level after 6 months of rhGH treatment. The mean IGF-1 concentration after 6 months of rhGH treatment was 156.45 ± 58.29 ng/ml (2.03 x lower limit of normal (LLN) vs. 66.89 ± 42.62 ng/ml (0.87 x LLN) at baseline. At baseline five patients had IGF-1 levels in the lower quartile of the normal range. We found increase in physical performance after 6 months of rhGH treatment measured by 6-minute walk test (6MWT): 614.0 ± 92.1 m vs. 539.7 ± 43.1 m(P <0.05), 30-second chair stand test (30sChST): 18.3 ± 5.6 repetitions vs. 13.0 ± 2.7 repetitions(P <0.05), Up-and-go test (UaGT): Mean task completion time was 5.21 ± 0.77 s vs. 5.78 ± 0.76 s(P <0.05), Handgrip strength test (HST): 36.2 ± 12.2 kg vs. 33.4 ± 10.2 kg(P <0.05). Divided by sex, the results are as follows. Women: 6MWT: 599.4 ± 57.0 vs. 527.9 ± 45.0, 30sChST: 17.6 ± 0.6 vs. 11.8 ± 1.6, UaGT: 5.42 ± 0.59 vs. 5.93 ± 0.63, HST: 26.8 ± 4.3 vs. 26.3 ± 5.5. Men: 6MWT: 630.4 ± 78.9 vs. 552.9 ± 39.3, 30sChST: 19.2 ± 7.3 vs. 14.5 ± 3.1, UaGT: 4.97 ± 0.92 vs. 5.62 ± 0.91, HST: 46.9 ± 8.6 vs. 41.4 ± 8.1.
Conclusions
Six-month rhGH replacement therapy resulting in normalization of IGF-1 level improves physical fitness of adult patients with severe GHD.

Severe growth hormone deficiency in siblings: a case study of GH1-related IGHD in a consanguineous family

Bogdan Pascu[1] & Diana Taifas[1]
[1]INSMC Alessandrescu Rusescu, Pediatric Endocrinology, Bucharest, Romania

Introduction
Isolated growth hormone deficiency (IGHD) is a rare autosomal recessive disorder caused by mutations or deletions in the *GH1* gene. It is characterized by early-onset severe short stature, extremely low levels of IGF-1, and a typical phenotype, including facial dysmorphism and genital abnormalities. IGF-1, a key mediator of growth hormone action, is critical for normal growth and development, and its deficiency leads to multisystemic consequences. Early genetic screening and treatment are essential to mitigate the impact of this condition on growth and overall health.
Case Presentation
This case study presents two siblings, aged 3 years and 7 months and 5 years and 10 months, diagnosed with severe growth deficiency and complex phenotypes. The consanguinity of their parents (second-degree cousins) and the family history, including an uncle with severe short stature (130 cm), suggest a significant genetic component. The phenotypes of the children were marked by facial dysmorphism (midfacial hypoplasia, hypoplasia of the nasal pyramid), micropenis (-3 DS), cryptorchidism, hypoplastic scrotum, and testicular hypotrophy. Both siblings presented with severe hypoglycemia at diagnosis (34 mg/dL and 25 mg/dL) and extremely low IGF-1 levels (<15 ng/ml and 26 ng/ml). Growth hormone therapy was initiated at different times, depending on the severity of their growth status. Somatropin treatment began 1 year and 9 months ago for both brothers. The older brother has shown a positive change in his growth trajectory, improving from -7.24 DS to -3.68 DS at present, while the younger brother has also demonstrated significant improvement, rising from -6.5 DS to -3.24 DS. Only the younger sibling has undergone genetic testing, which revealed a normal karyotype of 46,XY and a homozygous GH1 gene deletion was confirmed by WES.
Conclusions
This case highlights the importance of rigorous genetic and clinical monitoring in families with consanguinity. Differences in treatment timing and growth progression emphasize the phenotypic variability of growth hormone deficiency associated with the *GH1* gene. Additionally, severe hypoglycemia and extremely low IGF-1 levels complete the multisystemic picture of this rare disorder.

Background
The increasing application of digital health tools has enabled patient generated-health data (PGHD) to play a crucial role in clinical support and decision-making. However, data integration into practice remains a challenge, especially for managing long-term conditions such as growth disorders requiring, growth hormone (GH) therapy. Identifying key factors to support successful implementation of PGHD in clinical practice is essential to address adherence gaps and improving growth outcomes for children requiring GH in the Gulf Cooperation Council (GCC) region.
Aim
To develop recommendations for improving adherence to GH therapy and clinical outcomes based on the identified factors for PGHD integration into clinical workflows.
Methods
A participatory workshop was conducted on March 2, 2024, in Dubai, UAE, using the Nominal Group Technique (NGT). Twelve paediatric endocrinologists with significant experience in paediatric growth disorders and digital health from the GCC region along with a workshop chairman and 2 moderators, participated in the structured activity-based workshop. Discussions were guided by three clinical scenarios: naïve (recently diagnosed) patients, poor adherent, and poor responders. The experts individually identified and presented various types of PGHDs they considered relevant (silent generation and round robin), discussed them and each expert selected the top 5 PGHDs in order of relevance by voting.
Results
A total of 22 influencing factors for PGHD integrations were identified. In the first ranking round, the top factors were demographic data (21 points), patient feelings about treatments and satisfactions (19 points), and social background (17 points). Other significant considerations included reasons for missing injections and education needs (15 points each). The second ranking round prioritized factors, with social background (35 points) receiving the highest score, which included insurance, family support, and social structure. Injection context (34 points), including timing, comfort, and technical support during administration was the second highest ranked factor. Patient feelings about treatments and satisfaction (30 points) highlighted the importance of motivational and emotional aspects of adherence. The final discussion focused on determining how the identified factors could be integrated into clinical practice to support GH therapy.
Conclusion
The study highlights the significant role of the social background, treatment logistics, and patient satisfaction in promoting PGHD integration into GH workflows. Using region-specific digital solutions and collaborative healthcare practices amongst physicians, nurses, pharmacists and Patient Support Program members can improve adherence and patient outcomes in the GCC region.

Self-resolving regional lipodystrophy secondary to somatrogon therapy: a case report

Mohammad Awad[1,2] & Nandu Thalange[3]
[1]Al Jalila Children's Specialty Hospital, Pediatric endocrinology Department, Mansoura university, Egypt., Dubai, United Arab Emirates; [2]Pediatric endocrinology, Mansoura university., Manoura, Egypt; [3]Al Jalila Children's Specialty Hospital, Dubai, United Arab Emirates

Background
Growth hormone deficiency (GHD) is a condition characterized by insufficient production of growth hormone, resulting in impaired growth and development in children. Advances in therapy have introduced long-acting growth hormone analogs, such as somatrogon, offering the convenience of weekly dosing. While generally well-tolerated, localized side effects such as lipoatrophy at the site of injection, although rare, can occur. Lipodystrophy has not previously been reported as a side effect of Somatrogon therapy.
Case report
Patient Background: We report a 12-year-old boy with pyknodysostosis and growth hormone deficiency secondary to severe pituitary hypoplasia. Initially he was treated with daily Somatropin, but adherence issues led to us switching to weekly somatrogon therapy at a dose of 15 mg to address his GHD. At the start of treatment, his height SDS was -2.47.
Clinical Course
During a routine follow-up visit, regional lipodystrophy of the upper right arm was noted, characterized by a strikingly muscular appearance with prominent veins. Mother reported challenges with injection pain and the patient was insisting on using only his upper right arm for injections. No abnormalities were observed in his left arm or thighs. The appearance was attributed to repeated somatrogon injections at the same site. The importance of rotating injection sites was emphasized, and subsequently mother alternated between different anatomical sites, including the left arm and thighs.
Outcome
At his next follow-up visit, after three months, spontaneous resolution of the lipodystrophy was observed. Examination of his other injection sites showed no evidence of lipodystrophy. He continued therapy without interruption.
Conclusion
This case highlights regional lipodystrophy as a potential side effect of somatrogon therapy in a child with GHD. Timely identification and intervention through instituting proper injection site rotation led to successful resolution, without discontinuing therapy. This highlights the importance of patient and caregiver education on injection techniques to optimize therapeutic outcomes and adherence. Healthcare providers should remain vigilant for injection site reactions in patients receiving long-acting growth hormone therapies.
Acknowledgment
The authors thank the patient and his family for kindly agreeing to share their experience.

Filippi syndrome – a rare syndrome as a cause of short stature and primary amenorrhea

Bruna Silva[1], Beatriz Sousa[2], Sara Machado[2], Claudia Patraquim[3], Maria Miguel Gomes[3,4,5], Ana Antunes[3,4], Alexandra Rocha[6] & Sofia Martins[3,4]
[1]Unidade de Saude Local do Tâmega e Sousa, Endocrinology Department, Penafiel, Portugal; [2]Unidade Local de Saúde do Alto Ave, Pediatrics Department, Guimarães, Portugal; [3]Unidade Local de Saúde de Braga, Pediatrics Department, Braga, Portugal; [4]Unidade Local de Saúde de Braga, Pediatric Endocrinology and Diabetology, Braga, Portugal; [5]School of Medicine, Universidade do Minho, Braga, Portugal; [6]Unidade de Saude Local de Braga, Genetics Department, Braga, Portugal

Introduction
Filippi syndrome (FS) is a rare autosomal recessive disorder characterized by microcephaly, growth retardation, syndactyly, intellectual disability and dysmorphia. With only forty cases reported globally, diagnosis remains challenging.
Clinical Case
A 3-year-old girl, born full-term with fetal growth restriction (weight -2.26SDS, length -1.89SDS, head circumference -0.41SDS - Fenton 2013), was referenced to Pediatric Endocrinology due to short stature. There was no parental consanguinity and family history was unremarkable. Medical history included neonatal jaundice, ventricular septal defect and patent foramen ovale (spontaneously resolved by 1-year-old), umbilical hernia repair, recurrent otitis media and adenoidectomy. Dysmorphic features comprise high nasal bridge, thin alae nasi, square chin, clinodactyly of the fifth fingers bilaterally, and syndactyly of the second/third and third/fourth toes bilaterally. She also presented with microcephaly and intellectual development disorder at 6-years-old (Wechsler Intelligence Scale for Children III with Intelligence Quotient of 65, classification: very low). At 5 years-old she had height -2.72SD, weight -1.72SD, body mass index 0.15SD, family target height -1.82SD, bone age (BA) of 3-years-old and growth velocity of 8cm in the last year. Over time, growth slowed down, reaching -3.30SDS at 16-years-old. Thelarche and pubarche occurred at 10-years-old but menarche had never occurred. A whole exome study was carried out at 11-years-old, detecting decompound heterozygous variants in the CKAP2L gene (c.1092_1093del p.(Gln364Hisfs16) and c.1534_1537del p.(Lys512Hisfs13)), both classified as likely pathogenic, and FS was diagnosed. Analytical study excluded chronic disease. Endocrinological study showed: Follicle-stimulating hormone 7.55IU/L, Luteinizing hormone 3.26IU/L, estradiol 54.6 pmol/L (normal range 25.6-220.3). Growth hormone, cortisol and thyroid deficiency were excluded. Brain magnetic resonance was unremarkable. Abdominal-pelvic ultrasounds revealed hypoplastic uterus and small ovaries. Her last BA showed a delay of 1year (at 14-years-old). Currently, at 17-years-old, Tanner Stage M3P3, she remains amenorrheic, and ethinylestradiol was initiated.
Discussion
The authors present a case of FS, an extremely rare genetic disorder, emphasizing it as a cause of short stature and primary amenorrhea. Authors should share the evolution of these cases, to broaden the clinical spectrum of FS. This girl presented with delayed puberty although there are other cases described with precocious puberty. Although there is an association with neurologic abnormalities, seizures and growth hormone deficiency, they were not presented in this case. Early diagnosis can enable a personalized and timely approach to the patient's reproductive health, and also metabolic and bone well-being.

Survey of electronic growth chart use reveals inconsistent provision and awareness of functionality across the United Kingdom

Rebecca Moon[1,2], Reena Perchard[3,4], Nadine D'Silva[1], Helen Storr[5,6] & Justin Davies[1,7]
[1]Southampton Children's Hospital, University Hospital Southampton NHS Foundation Trust, Paediatric Endocrinology, Southampton, United Kingdom; [2]University of Southampton, MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom; [3]University of Manchester, Division of Developmental Biology and Medicine, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; [4]Royal Manchester Children's Hospital, Department of Paediatric Endocrinology, Manchester, United Kingdom; [5]Queen Mary University London, Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine, London, United Kingdom; [6]Barts Health NHS Trust, Paediatric Endocrinology, London, United Kingdom; [7]University of Southampton, Faculty of Medicine, Southampton, United Kingdom

Background
Growth monitoring is a fundamental aspect of routine paediatric care. Accurate charting, incorporating the use of appropriate reference data, is vital for clinical care to guide decisions to investigate and treat growth disorders. Electronic growth charting software can record and plot anthropometric data and generate standard deviation scores (SDS) for age and sex to aid clinical decision-making. We assessed the availability and types of electronic growth charts, reference data used and functionality of software across the United Kingdom (UK).
Methods
Paediatric endocrinologists and subspecialty trainees were invited via e-mail and the British Society for Paediatric Endocrinology and Diabetes newsletter to participate in an online survey on availability of growth charts and the functionality of available electronic growth charting software. Invitations to participate in the survey were distributed to secondary care paediatricians within each regional network by subspecialty trainees or paediatric endocrinology consultants. Where possible, commercial software developers were contacted to determine product specifications.
Results
100 responses were received between June and November 2024 from 82 different hospitals with wide geographical coverage across the UK. All 22 UK specialist paediatric endocrine centres responded. 72.0% of hospitals had electronic growth charting software available. 26.8% used only paper growth charts and one respondent reported having no access to any growth charts. All 22 specialist paediatric endocrine

centres used electronic growth charts, compared with 61.7% of secondary care centres ($P = 0.0006$). Twenty-eight different software packages were in use: locally developed software ($n = 16$ hospitals (27%)), commercially available products ($n = 12$ different in 43 hospitals). The growth reference data used was inconsistent: 41 (67%), 8 (13%) and 3 (5%) respondents reported using the UK-WHO data, the British 1990 reference data and WHO child growth standards, respectively. Nine (15%) respondents did not know the reference data used. Respondents using the same commercially available product frequently reported using different reference data. Additional functionality, for example, plotting body mass index and head circumference, ability to calculate SDS, prematurity adjustment, plotting of mid-parental height/target centile range and condition-specific charts were variably reported to be available even between users of the same commercially available software, and was frequently inconsistent with specifications reported by the software developers.

Conclusions

Electronic growth charts are not universally available to UK paediatricians. Where available, user knowledge of the growth reference data and software functionality was highly variable. We speculate these inconsistencies hinder comprehensive assessment of growth and may adversely affect clinical decision-making and patient care.

Real world data for the first year of treatment with somatrogon of children and adolescents with growth hormone deficiency (GHD)

Eirini Dikaiakou[1], Sofia Lekka[1], Ioanna Kosteria[1], Katerina Papadopoulou[1], Maria Margarita Rossolatou[1], Fani Athanasouli[1], Ioannis Panagiotopoulos[1], Sofia Zafiropoulou[2], Stefanos Fakiolas[2] & Elpis-Athina Vlachopapadopoulou[1]

[1]Children's Hospital "P.& A. Kyriakou", Department of Endocrinology-Growth and Development, Athens, Greece; [2]Children's Hospital "P.& A. Kyriakou", Biochemistry Department-Hormones Laboratory, Athens, Greece

Introduction

Somatrogon is a long-acting growth hormone (LAGH) that received marketing authorization by EMA on February 2022 for treatment of children older than 3 years old and adolescents with GHD. The aim is to describe the first-year treatment outcome in regards to change in height z-score, BMI z-score, IGF-1 z-score levels and HbA1c as well as to report possible adverse reactions of the patients treated with somatrogon in our department.

Methods

The study population consisted of 20 children (40% boys) with mean age 10.7 (SD 2.57) years with GHD, who were treated with Somatrogon from 1/2024 to 1/2025. Ten (50%) patients were naive to treatment with growth hormone (GH) while the other half switched from once-daily rhGH injection regimen. The dose of somatrogon was 0.66 mg/kg/week. Change in height z-score, BMI z-score, IGF-1 z-score, and HbA1c were calculated and compared using t-test. Furthermore, the adverse events during treatment were recorded as well as the tolerability, the adherence to treatment and the preferred injection schedule.

Results

Patients' height z-score increased significantly during the first year of treatment with LAGH (Ht z-score -1.93 (0.842) to -1.44 (0.856), p 0.005). A significant increase in patients' BMI z-score was appreciated (BMI z-score 0.041 (0.974) to 0.375 (0.967), p 0.001). There was no significant difference in IGF-1 z-score (0.341 (1.710) to 0.704 (1.28), p 0.167) in the whole group but there was a significant increase in the naive group IGF-1 z-score (-0.676 (1.48) to 0.42 (1.33) $P < 0.001$). One patient had IGF-1 > 2SDS the 4th day after the 4th dose, so the dose was decreased. IGF-1 normalized afterwards. Furthermore, HbA1c levels were within normal range for both groups. Two girls reported moderate to severe pain at the injection site after switching from daily rhGH injection regimen and one patient experienced transient erythema at the injection site. However, none of the patients discontinued treatment or returned to daily dosing. They all reported 100 % compliance.

Conclusion

In this group of patients, treatment with somatrogon was well tolerated, proved to be efficient in accelerating growth velocity and improving height z-score. A trend of increasing BMI z-score was noticed that needs further observation. The limitation of this study is the small number of children and the short duration. They are preliminary real-world data.

Growth hormone treatment response in patients with biologically inactive growth hormone

Amaya Vela[1,2,3], Nancy Portillo[1,2,4], Eneritz Lizarralde[2], Gema Grau Bolado[1,2,4], Amaia Sanchez Arlegui[2], Claudia Cifuentes Zamalloa[2] & Itxaso Rica[1,2,4]

[1]BIOBIZKAIA, Barakaldo, Spain; [2]Hospital Universitario de Cruces, Pediatric Endocrinology, Barakaldo, Spain; [3]Universidad del Pais Vasco (UPV/EHU), CIBERER, Barakaldo, Spain; [4]CIBERER, Barakaldo, Spain

Introduction

Biologically inactive growth hormone (BIGH) was described in 1978 as an indication for growth hormone (GH) treatment. Currently, this entity is not listed as an indication for GH treatment by some state committees. Initially, its diagnosis was equated with neurosecretory dysfunction, but this entity is no longer considered as its diagnosis is not methodologically feasible. At this time, the diagnosis in our community is defined based on clinical criteria (Height < -2 SDS and/or 2 SDS below target height and growth velocity (GV) < p25 and analytical criteria (Normal GH stimulation test, low IGF-1 levels with excluded proven cause, IGF-1 increased response to treatment with exogenous GH for 5 days).

Objectives

To analyse the clinical characteristics of patients monitored in a tertiary hospital who have been treated with GH for suspected BIGH. To find out whether there are side effects related to GH treatment.

Patients and methodology

Retrospective observational study of GH-treated patients with the diagnosis of BIGH. Thirty patients (seven girls) have been treated with normal neonatal anthropometry except for four SGA with catch-up. Twenty-six patients were analysed at three years. Variables studied: **at baseline:** Age (ABT), Height-SDS (HBT-SDS), BMI-SDS (BMIBT-SDS), Growth velocity-SDS (GSBT-SDS), difference between chronological age and bone age (CA-BABT); **Three years after GH treatment**: H3BT-SDS, BMI3-SDS, GS3T-SDS, CA-BA3T. In 18 patients who have reached **final height**: Final Height-SDS-Target Height-SDS (FH-SDS-TH-SDS) was studied. Statistical analysis using SPSS. Non-parametric Wilconson test for related samples.

Results

Mean target height-SDS: 0.9 ± 0.91 (2 patients with familial short stature). ABT (years): 9.3 ± 3.8 (range: 2.5-16). All the variables analysed are statistically significantly at 3 years, including CA-BA, than at baseline. Final height improved ($P < 0.01$) compared to baseline and at 3 years of treatment. In absolute numbers and by sex: In boys TH: 170,48 ± 3,30 and FH: 168,71 ± 3,50. In girls TH: 159.56 ± 10.8 and FH: 159.13 ± 5.50. Only two children's FH is short and 7 children exceed their target height.

Conclusions

1. Patients diagnosed with BIGH and treated with GH clearly improve their final height.
2. The majority reach the target height.

Table 1 The rest of the variables obtained are described in the table.

	AT BASE-LINE n: 30 median ± SDS	**3 YEARS AFTER GH** TREATMENT n: 20 median ± SDS	p	**END OF TREATMENT** n: 18 median ± SDS	p
HEIGHT (SDS)	-2.7 ± 0,69	-1.47 ± 0,65	< 0.01	-0.91 ± 0,64	< 0.01
BMI (SDS)	-1.08 ± 0,31	-0.90 ± 0,73	< 0.01		
GS (SDS)	-2.3 ± 1.52	2.13 ± 2.54	< 0.01		
CH-BA(SDS)	2.7 ± 1.15	1.79 ± 1.03	< 0.01

Intellectual and developmental function in children with Silver-Russell syndrome

Nataliia Muz[1], Eva Billstedt[2], Marita Grönlund[3] & Jovanna Dahlgren[1]

[1]Göteborg Paediatric Growth Research Center, Institute of Clinical Science, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden; [2]Gillberg Neuropsychiatry Centre, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Västra Götaland Regionen, Queen Silvia Childreńs Hospital, Gothenburg, Sweden; [3]Institute

of Neuroscience and Physiology, The Sahlgrenska Academy at University of Gothenburg, Department of Clinical Neuroscience, Gothenburg, Sweden

Background
Silver-Russell Syndrome (SRS) is a rare imprinting disorder characterized by intrauterine growth restriction, postnatal growth failure, and distinctive craniofacial features. While physical manifestations of SRS are well-documented, its impact on intellectual and developmental functions remains less understood. This study aims to evaluate cognitive and developmental outcomes in children with SRS to enhance understanding and improve clinical interventions.
Methods
To investigate if children with SRS have increased prevalence of cognitive disabilities, as well as autism spectrum disorder. A cohort of 28 children (16 boys) , mean age 11.6 years, were diagnosed with SRS and recruited from the Pediatric National Growth Hormone Registry. Children were followed at the national expert centre for SRS due to growth hormone treatment. Griffith's Mental Developmental scales and Wechsler Intelligence Scales were used according to age. Parents answered Autism Spectrum Screening Questionnaire (ASSQ) and autism diagnosis information was collected from medical records.
Results
In 12 children (43% of the cohort) we identified loss of methylation of chromosome 11p15 ($n = 11$) and maternal uniparental disomy of chromosome 7 ($n = 1$), in remain 16/28 no molecular cause was identified. The intelligence quotient (IQ) range was broad (61–142). Notably, 12 out of 28 children had an IQ below 85 (-1 SD), including 3 with an IQ below 70 (-2 SD), reflecting possible difficulties in learning and academic achievement. The mean full-scale IQ was significantly lower in "clinical SRS" compared to those with epigenetically confirmed SRS, 85.9 (15.8) and 104.9 (19.3), respectively. An uneven IQ profile between verbal IQ (VIQ) and performance IQ (PIQ) was observed in 14/26 children (54%), with nine of those showing a higher VIQ than PIQ. There was no significant association between molecular confirmed SRS and clinical SRS and uneven VIQ-PIQ profile. In 21/28 children one parent completed the ASSQ. Four children (two with and two without a clinical ASD diagnosis) scored above the cut-off (≥ 17), indicating autism-related symptoms. Six additional children reached either ASSQ cut off scores or had a diagnosis of Aspergeŕs syndrome.
Conclusion
Children with SRS present with variable intellectual and developmental outcomes, often exhibiting specific cognitive weaknesses and adaptive behavior challenges. Furthermore, ASD may be present. These findings underscore the need for early neurodevelopmental assessments to optimize learning and social adaptation.

Patient dynamics and real-world insights from a somatropin patient support program (PSP): outcomes from 24,000 treated patients in brazil

Paula Barquero[1], Tatiane Rodil[1], Alessandra Kanda[1], Ana Cristina Villela[1], Vitor Renosto[1], Cleber Sato[1] & Daniel Freire[2]
[1]Sandoz Brazil, São Paulo, Brazil; [2]Sandoz International Region, Medical Affairs, São Paulo, Brazil

Introduction
Suboptimal adherence to somatropin has negative effects on growth and has been observed in various populations. Patient support programs (PSPs) aim to improve treatment adherence and persistence. Since 2011, a PSP was implemented in Brazil to support all pediatric patients treated with Omnitrope® (somatropin), offering nurse assistance, needle supply, instructional visits, thermal packaging, sharps collectors, WhatsApp messages, and educational materials.
Objectives
Evaluate enrollment rate, persistence, drop-outs, and patient satisfaction with the somatropin PSP in Brazil, identifying reasons for treatment discontinuation.
Methods
The database comprised all pediatric patients enrolled in the PSP from July 2011 to December 2024. Participants stopping Omnitrope® treatment for any reason were discontinued from the PSP. Median persistence on program was calculated using Kaplan-Meier survival analysis ("event" being defined as participant leaving the program). From 2015 onwards, participants rated their satisfaction monthly using a 5-point Net Promoter Score (NPS).
Results
24,136 participants (56% boys, 42% girls, 2% N/A) were enrolled in the Omnitrope® PSP in Brazil. The average age at enrollment was 11.5 $\pm$2.86 years. The median duration of participation in the program for the entire population was 57 months. There was no significant difference in persistence between boys and girls. Enrollment rates spiked during shortages of other somatropin products and in the first weeks of the COVID-19 pandemic. The average dropout rate has stabilized around 2% of active participants since 2015. The main reasons for discontinuation were treatment success (32% of discontinuing participants), lost to follow-up (32%), and switching to another somatropin product (15%). The NPS ranged between 4.6 and 4.8 points annually from 2015 to 2024.
Discussion
Strategies to improve treatment compliance and persistence in children with growth disorders are important. This analysis of a somatropin PSP with a large database revealed high median persistence on program and excellent rating of the provided services. This can be related to the unique Brazilian somatropin market, where only vial-based products are reimbursed, and other somatropin options (including Omnitrope®) require out-of-pocket payment.
Conclusion
We analyzed the dynamics of a large somatropin PSP over 13 years. Patient enrollment was boosted by shortages of other somatropin products. The services provided by the PSP were highly appreciated by the patients and likely played a role in the observed high persistence in the program.

Background
For patients with growth disorders managed on recombinant human growth hormone (r-hGH) therapy, the Growzen™ ecosystem (previously Easypod® Connect) provides an innovative connected injection device transmitting adherence data, empowering healthcare professionals to monitor real-time patient adherence.
Aim
This SCOPE (Study and Collection of Observational data for Patients with Easypod® Connect) study aims to use 5-year data from Growzen™ ecosystem to evaluate adherence and its key-driving factors in patients with growth disorders from France.
Methods
Adherence data for patients aged 4–17 years at treatment start and <18 years were extracted from Growzen™ ecosystem between June 2018–December 2023. The following potential key-driving factors for adherence were assessed: indication (Growth Hormone Deficiency [GHD] and Small for Gestational age [SGA]), sex, age, and treatment regimen (7 vs 6 days/week).
Results
Adherence data from 481 patients (265 GHD, 157 SGA, 13 Turner Syndrome, 46 other/unknown indications) across 19 centers were analysed. Of these, 256 patients followed a regimen of 7 days/week and 225 patients followed a regimen of 6 days/week. Mean age at treatment start was 9.9 years in all patients, 10.5 and 8.8 years in patients with GHD and SGA respectively. The proportion of high-level adherence ($\geq 85\%$) was 85% across all patients and was similar between GHD and SGA patients. During the first 12–18 months, adherence levels were comparable for boys and girls, with nearly 90% high-level adherence. A slight difference in the adherence level was found between boys and girls over time,

with a larger portion of girls having a high-level adherence after couple of years. A high-level adherence was observed in approximately 95% patients up to 5 years of age and 90% between 5 and 12 years. This decreased after the age of 12 years with 72% of patients having a high-level adherence at 17 years of age. The proportion of high-level adherence was 82% for 7 injections/week regimen and 88% for 6 injections/week regimen, but the difference was not statistically significant after adjustment for patient ages (10.5 years with 7 days/week, 9.3 years with 6 days/week).

Conclusion

The adherence level over the study period was high, demonstrating good engagement level of patients using the connected device for the daily administration of r-hGH therapy. Among all potential key-driving factors for adherence, the age at treatment start showed the highest impact on the level of adherence, emphasizing the need for early initiation of treatment for better outcomes.

Paradoxical growth in multiple pituitary deficiencies: two clinical cases of obese pediatric patients

Lara Devilli[1,2], Laura Corbelli[1,2], Alessio Rossi[1,2], Sara Soldovieri[1,2], Gaia Varriale[2], Franco Ricci[2] & Stefano Stagi[1,2]

[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Diabetology and Endocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy

Introduction

Growth hormonal (GH) deficiency (GHD) is typically associated with impaired growth and short stature. Nevertheless, instances of normal growth have been reported in some pathological conditions, such as combined pituitary hormone deficiency following the resection of craniopharyngioma, septo-optic dysplasia and overgrowth syndromes despite GHD. We report two patients with obesity and multiple pituitary deficiencies exhibiting normal growth.

Patient 1

A 11-year-old female was evaluated for obesity. Height was 145.6 cm (-0.17SDS) within the mid-parental target, BMI 25.9 (+2.37SDS). Pubertal evaluation was B1 PH1 AH1. Homa index 3.2. History was positive for transient hypoglycemia at birth, normal postnatal growth and minor language delay. Endocrine assessment disclosed low FT_4 with inappropriately normal TSH consistent with central hypothyroidism; patient revealed significantly low IGF-1 (39 ng/ml), IGFBP-3 (2.04 mg/dL), and central ACTH deficiency. GH stimulation tests showed absent GH response. Magnetic resonance imaging (MRI) revealed a small adenohypophysis, absent pituitary stalk, and ectopic neurohypophysis. So, diagnosis was congenital panhypopituitarism was made and the patient began treatment with hydrocortisone, L-thyroxine, and GH. Genetic investigations are ongoing.

Patient 2

A 11-year-old male was evaluated for severe obesity. Height was 158.65 cm (+1.44SDS) above his mid-parental target, BMI 33.5 (+2.59SDS). Tanner stage was T 10 ml PH3 AH2. Abdominal ultrasonography indicated severe steatosis with metabolic syndrome and very high leptin level. Oral glucose tolerance test disclosed severe insulin resistance. Thyroid evaluation revealed secondary hypothyroidism, low IGF-1 levels (39 ng/ml) that persisted after L-thyroxine treatment. Prolactin levels were elevated, while adrenal function and gonadotropin levels were normal. GH stimulation tests showed GH deficiency. MRI showed a small stalk with normal pituitary gland. Despite excellent growth, clinical and laboratory findings suggested combined pituitary deficiency. Hormonal replacement therapy with L-thyroxine and GH was started. Exome sequencing is currently in progress.

Conclusion

The paradox of normal growth in patients with confirmed growth hormone and L-T4 deficiency remains enigmatic. Similar cases have been documented in obese individuals. One hypothesized mechanism involves hyperinsulinism, given the high homology between insulin receptors and IGF-1 receptors. Furthermore, hyperprolactinemia, hyperleptinemia and GH variants have been proposed as contributing factors in this phenomenon. The intricate interplay between these hormonal imbalances and growth regulation warrants further investigation to elucidate the underlying mechanisms. Additionally, cases of normal growth despite GHD have been described in patients with mutations in the HESX1 gene, associated with combined pituitary hormone deficiency. Ongoing genetic analyses in our patients will advance our understanding.

Growth hormone insensitivity in an infant with LZTR1 mutation and growth failure: a case report

Giulia Del Medico[1,2], Lara Devilli[1,2], Alessandro Barbato[1,2], Giovanna Traficante[3], Silvia Favilli[4], Angela Peron[3,5], Iacopo Olivotto[6], Marco Tartaglia[7] & Stefano Stagi[1,2]

[1]Endocrinology and Diabetology Unit, Meyer Children's Hospital IRCCS, Florence, Italy; [2]Health Sciences Department, University of Florence, Florence, Italy; [3]Medical Genetics Unit, Meyer Children's Hospital IRCSS, Florence, Italy; [4]Department of Pediatric Cardiology, Meyer Hospital IRCCS, Florence, Italy; [5]Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Università degli Studi di Firenze, Florence, Italy; [6]Department of Clinical and Experimental Medicine, University of Florence and Meyer Children's Hospital IRCCS, Florence, Italy; [7]Molecular Genetics and Functional Genomics, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy

Introduction

Growth hormone (GH) insensitivity (GHI) results from a spectrum of abnormalities in the action of GH, presenting clinically as either mild short stature with normal physical appearance or severe dysmorphic short stature. In Noonan syndrome (NS) variable GHI has been reported, especially in individuals with *PTPN11* mutations. However, limited data are available on *LZTR1* mutations.

Case report

A 1.8-year-old male patient was referred to our Pediatric Endocrinology Unit for growth failure. His length was 80.5 cm (-1.3 SDS), and height velocity was significantly reduced (-1.8 SDS). The patient was born at 38+2 weeks of gestation following a pregnancy complicated by polyhydramnios in the 3rd trimester. Prenatal echocardiography revealed hypertrophy of the septum and right sections of the heart. At birth, his weight and length were adequate (3600 g and 53 cm, respectively). On the first day of life, he experienced a Sudden Unexpected Postnatal Collapse (SUPC). Postnatal cardiological evaluation confirmed hypertrophic cardiomyopathy with associated electrocardiographic abnormalities. Clinically, the patient exhibited features suggestive of RASopathy, therefore a genetic evaluation was performed. During the follow-up for growth failure, laboratory investigations revealed markedly reduced levels of IGFBP-3 (0.61 mg/L; range 1.20 - 3.30) and IGF-1 (13 ng/ml; range 18-156). Abdominal ultrasound was normal. Blood tests showed an increased INR (1.37, range 0.92-1.14) and reduced prothrombin time (64%, range 70-100). Cranial MRI was unremarkable. An arginine test was performed and revealed normal GH peak (14.60 ng/ml) with persistently significantly reduced IGF-1 and IGFBP-3 levels. Genetic analysis identified a heterozygous mutation in the *LZTR1* gene (variant c.734G>A, p.Gly245Glu), classified as pathogenic and associated with NS.

Conclusions

This case confirms that some *LZTR1* mutations can be associated with GHI. However, biallelic *LTZR1* variants have been reported linked with GH deficiency (GHD). The molecular mechanisms causing GHI or GHD in *LTZR1* remain unclear. An accurate auxological and biochemical evaluation is essential to distinguish these two conditions and establish a correct work-up and follow-up, as well as an adequate treatment strategy.

Autosomal recessive ovarian dysgenesis associated to gh-deficiency and pituitary hyperplasia: a case report

Davide De Brasi[1], Elisabetta Scarano[1], LIVIA BARBA[1], Roberto Novizio[1], domenico serino[1], Vincenzo Novizio[1], Chiara Vitiello[2], Roberta Petillo[3] & Francesco Scavuzzo[1]

[1]Antonio Cardarelli Hospital, Naples, Italy, Endocrinology Department, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione, Naples, Italy; [3]Antonio Cardarelli Hospital, Naples, Italy, Genetics Department, Naples, Italy

Introduction

Ovarian dysgenesis (OD) is a major cause of hypergonadotropic hypogonadism and premature ovarian insufficiency (POI) in adolescent females. X chromosome numerical or structural abnormalities have historically been the most frequent congenital etiology of this condition. More recently, additional pathogenetic mechanisms have been identified, including Fragile X premutation and mutations in genes involved in meiosis, DNA damage repair, and homologous chromosome

recombination.
PSMC3IP
is a novel candidate gene associated with autosomal recessive OD, playing a crucial role in homologous chromosome pairing and recombination during meiosis.
Case Report
A 13-year, 6-month-old adolescent girl, the firstborn of apparently non-consanguineous parents, was referred for evaluation due to short stature, delayed pubertal development (Tanner stage PH1 B1), and primary amenorrhea. Psychomotor development was normal. Baseline biochemical tests, thyroid function, and celiac serology were unremarkable. However, FSH levels were repeatedly elevated, while estradiol, AMH, and testosterone levels were low or undetectable. LH levels were in the high-normal range. IGF-1 levels were low (108 ng/ml, < -2 SD), and bone age was delayed by more than three years. Karyotype analysis (50 metaphases) revealed a normal 46XX pattern, and FISH analysis did not detect Yp11.3 sequences. Due to short stature, GH stimulation tests (arginine and clonidine after estradiol priming) were performed, showing low GH peaks (6.83 ng/ml and 2.32 ng/ml, respectively), confirming GH deficiency. Brain MRI revealed diffuse pituitary gland enlargement without focal lesions. Ophthalmological evaluation was normal. Consequently, rhGH therapy was initiated at age 14 and is currently ongoing. Further investigation of POI through pelvic ultrasound revealed marked uterine and ovarian hypoplasia. Autoantibodies against adrenal and ovarian tissues were undetectable. Genetic testing, including SNP microarray and Fragile X (FMR1) analysis, did not reveal CGG repeat expansion nor significant chromosomal rearrangements. Whole-exome sequencing identified a homozygous likely pathogenic variant (Class IV) in **PSMC3IP** (c.429_430del; p.Arg143Serfs*5). At 14 years and 6 months, estradiol replacement therapy was initiated and is ongoing.
Discussion
Only a few cases of autosomal recessive OD due to **PSMC3IP** variants have been reported to date. This case highlights the role of meiotic arrest in OD pathogenesis and supports the observation that distal (C-terminal) pathogenic variants in **PSMC3IP** are preferentially associated with OD. Additionally, the unique co-occurrence of pituitary hyperplasia and GH deficiency expands the clinical spectrum of this novel genetic condition.

Experience with vosoritide for achondroplasia: insights from Kazakhstan

Marzhan Rakhimzhanova[1], Assel Issabayeva[2], Bikhadisha Bimurat[1], Akmaral Nurbekova[3] & Aigul Durmanova[1]
[1]"University Medical Center" Corporate Fund, Astana, Kazakhstan; [2]Nazarbayev University School of Medicine, Astana, Kazakhstan; [3]NpJSC "Kazakh National Medical University", Almaty, Kazakhstan

Background
Vosoritide is an engineered C-type natriuretic peptide analog and the first pharmacological, precision treatment approved for use in children with achondroplasia. While international guidelines provide practical guidance for healthcare providers worldwide, real-world experience data remains limited, particularly in Central Asia. This study aims to present our experience with Vosoritide and highlight challenges to treatment.
Methods and Results
Data were collected from hospital records, including patients receiving Vosoritide therapy at the "University Medical Center" Corporate Fund (Astana). In total, 38 children in Kazakhstan are receiving Vosoritide. The first 10 children were enrolled on 10 March 2023 in Almaty, and the last 14 patients, aged between 2.8 and 12.6 years, started treatment in December 2024 in Astana. The most common complications of achondroplasia among our children are ventricular enlargement with symptoms of hydrocephalus, spinal kyphosis, respiratory disorders, and symptoms of spinal canal stenosis. Worldwide, achondroplasia is the most common skeletal dysplasia, estimated to affect about 1 in every 40,000 children. There are approximately 200 children with this diagnosis in Kazakhstan, meaning only around 20% of children are receiving the treatment, highlighting the gap in access to therapy.
Discussion
Our findings align with international data on Vosoritide's safety profile. However, significant challenges remain, including limited accessibility and the high cost of medication, that create complex regulatory pathways and barriers to therapy. Additionally, based on our experience, we emphasize the significance of counseling and training programs before initiating treatment. Possible cases of treatment refusal due to divided opinions highlight the need for psychological preparation. Frequently, parents fear potential adverse effects or question the efficacy of the drug, which underlines the need for family education sessions. We also recognize the psychological trauma associated with daily injections experienced by children of different ages, which may lead to non-compliance. A multidisciplinary strategy, including parental support and structured counseling, may improve adherence to the treatment.
Conclusion
This study provides valuable data on the use of Vosoritide in Central Asia. While the treatment has improved quality of life, accessibility remains a key concern. Future efforts should also focus on the long-term safety and efficacy of the therapy, which will be vital in optimizing patient education programs and ensuring psychological support for families. Additionally, monitoring and early intervention for complications, enhancing the quality of health professionals, and streamlined regulatory approval procedures are crucial to improving treatment outcomes.

Optimizing therapies for advanced bone age in obesity-related short stature, cah, precocious puberty, and sga: an updated view

Fawzia Alyafei[1], Ashraf Soliman[1], Ahmed Elawwa[1], Shayma Ahmed[1], Noora AlHumaidi[1], Noor Hamed[1], Nada Alaaraj[1] & Ahmed Khalil[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Advanced bone age is a critical factor limiting height outcomes in growth disorders, including obesity-related short stature, congenital adrenal hyperplasia (CAH), precocious puberty, and small-for-gestational-age (SGA) conditions. Therapies such as growth hormone (GH), aromatase inhibitors (AIs), and gonadotropin-releasing hormone agonists (GnRHa) are used either independently or in combination to enhance height potential and manage bone age progression.
Objectives
This review aims to assess and compare the effectiveness of GH, AIs, and GnRHa therapies in treating advanced bone age across pediatric growth disorders. It evaluates their impact on height standard deviation score (HtSDS), predicted adult height (PAH), and bone age modulation.
Methods
Studies spanning 2000–2024 were analyzed. These studies encompassed diverse pediatric conditions with advanced bone age treated with GH, AIs, GnRHa, or combinations. Data on PAH improvements, bone age control, and side effects were extracted, focusing on therapeutic outcomes across conditions.
Results
A total of 25 studies were analyzed to evaluate therapeutic strategies for advanced bone age across four conditions: obesity-related short stature, CAH, precocious puberty, and small SGA. The studies highlighted the efficacy of GH therapy, GnRHa, and AIs, either alone or in combination. Six studies reported that GH combined with GnRHa or AIs improved predicted adult height and controlled bone age progression in obesity-related short stature, with early intervention yielding the best outcomes. For CAH, five studies demonstrated that combination therapies (e.g., GH + GnRHa + AI) significantly improved height SDS while controlling androgen-induced bone maturation, especially in prepubertal patients. Eight studies on precocious puberty confirmed the effectiveness of GnRHa in delaying bone age advancement, with combination therapy (GnRHa + GH or GnRHa + AI) yielding superior height outcomes. In four studies examining SGA, GH alone or in combination with AIs consistently promoted significant height gains and moderately delayed bone age, particularly with early intervention. Across all conditions, combination therapies outperformed monotherapy in managing bone age progression and optimizing growth, with minimal but manageable adverse effects.
Discussion
The findings underscore the importance of condition-specific approaches to optimize outcomes. Early diagnosis and intervention are critical, particularly in obesity-related short stature and SGA, where early skeletal maturation poses significant barriers to achieving optimal height.
Conclusion
Combination therapies tailored to the underlying pathology of advanced bone age provide the most effective strategies for improving height and managing bone age progression in growth disorders. Future research should focus on safety, and personalized treatment algorithms to maximize benefits across conditions.

A rare cause of short stature: a case with a TBX6 gene variant

Edanur Bulut[1], Nihal Gül Uslu[2,3], Samim Ozen[2] & Hilmi Bolat[1]
[1]Balıkesir University Faculty of Medicine, Department of Medical Genetics, Balıkesir, Türkiye; [2]Ege University Faculty of Medicine, Pediatric Endocrinology and Diabetes, İzmir, Türkiye; [3]Ege University Faculty of Medicine, Pediatric Endocrinology and Diabetology, İzmir, Türkiye

Introduction

Spondylocostal dysostosis is a genetically inherited disorder characterized by malformations of the ribs and vertebrae. Heterozygous and biallelic variants in TBX6 gene have been linked to vertebral and rib malformations, as well as spondylocostal dysostosis. In this case report, we aimed to contribute to the literature by presenting the clinical findings of our patient with TBX6 gene variant, one of the rare causes of spondylocostal dysostosis.

Case Report

A 14-year-old male patient was referred to the endocrinology clinic due to short stature. His parents were first-degree relatives. The mother's height was 162.1 cm, and the father's height was 169.2 cm, with a target height of 172.15 cm (-0.66 SDS). On physical examination, the patient's weight was 41.5 kg (-1.7 SDS), height was 142.5 cm (-3.02 SDS), BMI was 20.4 (-0.05 SDS), and head circumference was 54 cm (-1.33 SDS). His pubertal stage was Tanner A+P1, with testicular volumes of 4 ml bilaterally. Laboratory investigations, including complete blood count, thyroid function tests, and biochemical analyses, were within normal limits. Serum IGF-1 was 152 µg/L (115-489), and IGFBP3 was 3.85 mg/L (3.21-6.93). Due to severe short stature, a growth hormone stimulation test revealed a peak GH level of 11.2 µg/L (normal). Urinary mucopolysaccharide excretion was normal, ruling out mucopolysaccharidosis. Whole exome sequencing (WES) identified a likely pathogenic (NM_004608.4) heterozygous c.2T>A p.Met1Lys missense variant in the TBX6 gene. It was determined that the detected variant was inherited from the father, who exhibited similar clinical features.

Discussion

According to The Human Gene Mutation Database Professional 2023.4, a total of 84 different variants have been reported in the TBX6 gene, including 34 missense/nonsense, 6 splicing, 1 regulatory, 9 small deletions, 8 small inversions, 21 gross deletions, and 5 gross insertions. Our case presented with a clinically relevant and frequently observed missense variant in this gene. The identified variant was not found in the gnomAD and ClinVar databases and was classified as likely pathogenic according to ACMG criteria. Phenotypes associated with TBX6 gene variants include short stature, short neck, rib anomalies, scoliosis, hemivertebrae, and butterfly vertebrae. Recognizing spondylocostal dysostosis in the prenatal period allows for the exclusion of spondylothoracic dysostosis, assessment of recurrence risk in siblings, and provision of genetic counseling. In the postnatal period, early diagnosis facilitates physiotherapy to improve quality of life and increase lifespan. Additionally, surgical intervention can be performed for stabilization of chest wall and spinal deformities.

A rare disease presented with bow legs

Kent Ho-chung Yau[1], Suki Suk-yan Chan[1] & Jojo Ka-yee Chan[1]
[1]Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, Hong Kong

Myhre syndrome is a multisystem progressive connective disorder with highly distinctive findings of craniofacial dysmorphism, short stature, joint limitation, restrictive lung and cardiovascular disease, progressive and proliferative fibrosis. We report a 3-year-old girl with Myhre syndrome. The girl was born full term with birth weight of 2705gram from a non-consanguineous Chinese couple. Antenatal Down syndrome screening, noninvasive prenatal testing and morphology scan were unremarkable. However, maternal grandparents were consanguineous. Among their 12 children, many suffered from congenital anomalies and succumbed. After birth, parents had no developmental concern. She walked at 11 months. Bow legs had progressively worsened since 15 months. When she was seen at 18 months, body length was 1.3cm below 0.4th centile, body weight at 9th centile, and head circumference at 50th centile. Clinical examination revealed facial dysmorphism – short palpebral fissures, hypoplastic maxilla, short philtrum, narrow mouth, prognathism and small ears. Skeletal examination showed brachydactyly, limited elbow and shoulder extension, genu varum with intercondylar distance measured 10cm, and waddling gait. Bone biochemistry revealed calcium 2.42mmol/l (2.15-2.55), phosphate 1.29 mmol/l (0.72-1.43), ALP 1358IU/L (130-330), total 25-hydroxyvitamin D 38nmol/l (30-49nmol/l mild deficiency), and parathyroid hormone 5.8pmol/l (1.6-6.9). Skeletal survey showed rickets features including metaphyseal fraying and spraying with rachitic rosary over costochondral joints. Other differential diagnosis included chondrodysplasia. There were no obvious features for other skeletal dysplasia or mucopolysaccharidosis. Urinary organic acid, plasma amino acid, serum free carnitine and acylcarnitine pattern were unremarkable. Urine glycosaminoglycan/creatinine ratio measured 27.7g/mol Cr (<29.9) and no pathological pattern detected by electrophoresis. In view of mild vitamin D deficiency, cholecalciferol 1000 IU daily was initiated and daily calcium intake of 500mg was ensured. As mild vitamin D deficiency could not account for craniofacial dysmorphism and joint limitation, genetic testing was arranged. Whole exome sequencing detected a de novo pathogenic heterozygous NM_005359.6(SMAD4):c.1486C>T p.(Arg496Cys) variant. This is a missense variant located in the MH2 domain of SMAD4 gene. Another de novo variant of uncertain significance heterozygous NM_018486.3(HDAC8):c.1133A>G p.(Ter378Trpext*16) was detected. This is a stop loss variant. Echocardiogram at 30 months was unremarkable. Developmental assessment at 42 months revealed a 9-month global developmental delay. Early education and training were continued. After 8-month vitamin D supplementation, bone biochemistry was mostly normal – calcium 2.56mmol/l, phosphate 1.67mmol/l, ALP 402IU/L, and total 25-hydroxyvitamin D 114nmol/l. Serial follow up demonstrated improvement in genu varum – intercondylar distance measured 5cm and 4cm at 24 months and 34 months respectively.

JOINT3776

A case of spondyloepiphyseal dysplasia, kimberley type, caused by a novel variant in the ACAN gene

Nataliya Volevodz[1,2], Kseniya Zabudskaya[1] & Natalia Mokrysheva[1]
[1]National Medical Research Center for Endocrinology, Moscow, Russian Federation; [2]Moscow Regional Clinical Research Institute named after M.F. Vladimirsky (MONIKI), Moscow, Russian Federation

Introduction

Short stature is a common reason for seeking medical attention in childhood. Clinical variability and genetic heterogeneity make it difficult to identify the underlying cause in a significant portion of patients. One of the genes associated with a wide phenotypic spectrum of non-syndromic short stature is *ACAN*. The aggrecan protein, encoded by the *ACAN* gene, is a major proteoglycan component of the extracellular matrix of cartilage. Aggrecan plays a critical role in maintaining the structure necessary for the function of joints. We present a clinical case of autosomal-dominant spondyloepiphyseal dysplasia type Kimberley, caused by a novel variant in the *ACAN* gene.

Materials and Methods

A 3-year-8-month-old boy was referred to us because of his short stature. Birth weight 3000 g, length 48 cm. Early development was without any issues. There is no family history of short stature. The mother's height is 164 cm, the father's height is 184 cm, and the target height is 181.5 cm (SDS of target height: +0.65 SD). Upon examination, the patient's condition was satisfactory. His height was 89.5 cm (SDS: -2.67), weight 12.5 kg (SDS BMI: -0.12), with a high forehead and relative macrocephaly. No instrumental data indicated a disruption in bone age.

Results

Molecular genetic testing was performed using a targeted panel for "Connective Tissue Diseases" via next-generation sequencing (NGS). A previously undescribed heterozygous variant was identified in the *ACAN* gene (NM 001369268.1): c.1793G>A, p.(Cys598Tyr), which was further validated by Sanger sequencing. Segregation analysis confirmed the variant as *de novo* in the family. Based on the ACMG pathogenicity criteria, the variant was classified as likely pathogenic and causal for spondyloepiphyseal dysplasia, Kimberley type with an autosomal-dominant inheritance pattern.

Conclusion

The polyetiological nature of short stature in pediatric practice requires expanded molecular genetic testing methods, such as targeted panels, whole-exome sequencing, and whole-genome sequencing. Identifying the causal variant allows for diagnosis verification, determination of further observation and treatment strategies for the patient and provides a health prognosis for the family.

Evaluation of factors that predict a good response to growth hormone treatment in patients with isolated growth hormone deficiency in first year of therapy - single centre study

Milica Ignjatović [1,2], Sandra Stankovic[1], Vesna Cvetković[1], Milica Jakovljevic[1], Marija Andrejevic[1] & Milan Golubovic[1]
[1]Pediatric Clinic, University Clinical Center, Nis, Serbia, Endocrinology, Nis, Serbia; [2]Pediatric Clinic, Endocrinology, University Clinical Center, Nis, Nis Medijana, Serbia

Introduction
Response to growth hormone (GH) treatment varies greatly not only between different conditions, but even between patients with same condition ("poor responders" vs. "good responders"). Many publications suggest that multiple factors influence response to GH treatment. Some studies have reported that body mass index, mid-parental height (MPH), bone age, height at the start of GH treatment and GH peak during provocative tests (insulin and L-DOPA test) are important factors for successful outcome of growth hormone treatment (rhGH) in children with isolated growth hormone deficiency (IGHD).
Objective
Aim of the study is to determine factors associated with better response to growth hormone supplementation during first year of therapy.
Methods
This was a retrospective analysis of 95 patients under the age of 15 years who were diagnosed with isolated GH deficiency using insulin and L- DOPA as stimulants, for assessment of GH secretion, and who received rhGH therapy for at least 1 year in the Pediatric Clinic of University Clinical Centre Nis between 01.01.2017- 01.01.2022.
Results
We collected data of 95 children (53 male and 42 female) with IGHD who had received rGH. The mean (SD) age at diagnosis and initiation of rGH was 10,31 ± 3,27 years, while the mean bone age was 8.59 ± 3.14 years. 44,2 % of patients were in prepubertal stage (Tanner 1). The Δheight SDS during the first year of GH treatment was correlated negatively with BMI SDS ($r = 0.017$, P 0,87), maternal height ($r = 0.70$, $P = 0.50$) and chronological age at the start of GH therapy ($r =$ 0,279, P 0,187), but positively correlated with bone age ($r = 0.926$,$P < 0.01$), paternal height ($r = 0.265$,$P < 0.01$) and target height ($r = 0.300$,$P < 0.01$). Also the patients were classified into two groups according to the peak GH values in the provocation tests (group I: peak GH < 3 µg/L, $n = 61$; group II: peak GH between 3 and 7 µg/L, $n = 34$). There was not a statistically significant association between the first-year HV SDS and the peak GH value in provocation tests in multiple regression analyses.
Conclusions
The present model to predict first-year response to GH treatment might allow more tailored and personalized GH treatment in prepubertal children with idiopathic GHD.

Mauriac syndrome in a teenager with dual autoimmune disorders: a case report

Rihab Khochtali[1], Hamza Elfekih[1], Wiem Saafi[1], Amira Yanes[1], Imen Halloul[1], Taieb Ach[1], Ghada Saad[1] & Yosra Hasni[1]
[1]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Endocrinology and Diabetology Department 4000, Sousse, Tunisia

Introduction
Mauriac syndrome is a rare complication of poorly controlled long-standing type 1 diabetes mellitus (T1DM). It is characterized by hepatomegaly due to glycogen accumulation, growth failure and delayed puberty. We present a case of Mauriac syndrome in a patient with T1DM and coeliac disease, emphasizing this uncommon association.
Case Presentation
A 14-year-old male with a 5-year history of T1DM and a 2-year history of coeliac disease presented with recurrent severe hypoglycemic episodes over the past two months. Despite adhering to insulin therapy (0.6 IU/Kg/day) and maintaining a gluten-free diet, his glycemic control remained inadequate, with an HbA1c level of 8%. Upon admission, his venous blood glucose was critically low at 0.35 g/L. The patient exhibited significant growth and pubertal delays, with a weight of 38 Kg, height of 1.45 m (-2 standard deviations), body mass index of 18 Kg/m^2, and Tanner stage 1. Physical examination revealed hepatomegaly, with a liver span of 19 cm. Laboratory investigations showed mixed dyslipidemia (total cholesterol: 4.5 g/L [1.7–1.99], triglycerides: 2.8 g/L [1–1.5]) and elevated liver enzymes (ALT 3x ULN; AST 2x ULN). Other laboratory findings included normal coagulation profile, bilirubin, renal function, serum iron, hemoglobin, and ferritin levels. Autoimmune markers such as antinuclear antibodies, anti-LKM1, anti-smooth muscle antibodies, and anti-mitochondrial antibodies were negative. TSH and cortisol levels were within normal ranges, and viral hepatitis serologies were negative. Both insulin and C-peptide levels, taken during hypoglycemia, were suppressed (insulin:0.6 uUI/ml[4-23]; C-peptide: 0.02ng/ml[0.9-3.7]). Abdominal ultrasound revealed homogeneous hepatomegaly. A liver biopsy confirmed extensive glycogen deposition using periodic acid-Schiff (PAS) staining, leading to a diagnosis of Mauriac syndrome.
Conclusion
The simultaneous occurrence of Mauriac syndrome and coeliac disease poses a distinct challenge in diabetes management, complicating efforts to achieve optimal glycemic control. Although it is uncommon, Mauriac syndrome should be considered in patients with poorly controlled T1DM, particularly when symptoms such as hepatomegaly and growth retardation are present. Effective glycemic management is crucial for minimizing glycogen accumulation and hepatomegaly, which in turn improve growth and promote normal pubertal development.

Effects of growth hormone therapy in patients with prader-willi syndrome: the first algerian experience

Sakina Kherra[1], Asmahane Ladjouze[1], Fadila Bouferoua[1], Yasmine Ouarezki[1], Adel Djermane[1], Sihem Bellouti, Hassiba Sahli[1], Latifa Sifour[1], bensalah meriem[1], Kahina Mohammedi[1], Chikh Amina[1] & Zeroual Zoulikha[1]
[1]University Hospital, Nefissa Hamoud, Paediatric Unit, Medical University, Algiers, Algeria

Introduction
Prader-Willi syndrome (PWS) is a rare genetic neurodevelopmental disorder resulting from the loss of expression of paternally inherited, imprinted genes on chromosome 15q11.2–q13.1. It is characterized by cognitive, behavioral, and endocrine abnormalities, including hypotonia, hyperphagia, obesity, short stature, and growth hormone (GH) deficiency. The estimated birth prevalence of PWS ranges between 1 in 15,000 to 1 in 25,000 live births.
Objective
This study aims to evaluate the effects of GH therapy on BMI and stature in Algerian children with PWS by comparing outcomes between GH-treated and untreated patients. We present a multicentric cohort of 46 children aged 0 to 16 years, providing the first Algerian data on auxological and metabolic outcomes in PWS.
Methods
This is a retrospective, multicenter study conducted across six Algerian hospitals (outpatient clinics) over 17 years (2007–2024). Data were collected from a national database, including medical records and endocrine profiles of children and adolescents diagnosed with PWS.
Results
The median age at diagnosis was 5.1 years (range: 0–14 years), with 7 patients (17.2%) diagnosed in the neonatal period. During the study period, three deaths (6.52%) were recorded, including two cases (4.34%) related to morbid obesity. At the most recent follow-up (median age: 6.1 years; range: 1–16 years), Median BMI was 23.48 ± 9.51 kg/m^2 (range: 11–56 kg/m^2). 65% of patients were overweight or obese, including 13% with morbid obesity (BMI > 40 kg/m^2). Glucose intolerance was detected in 4.34% of patients, and two cases (4.34%) developed type 2 diabetes. Growth hormone deficiency was diagnosed in 42 patients (93%), but only 11 patients (24.4%) received GH therapy. After one year of GH treatment, GH-treated patients showed a significant increase in height SDS ($+1$ SD height gain) compared to the untreated group ($p < 0.05$). GH-treated patients also exhibited a BMI reduction to 20.49 kg/m^2, whereas untreated patients experienced a progressive increase in BMI
Conclusion
GH therapy in children with PWS significantly improves height growth and helps regulate BMI, demonstrating a positive impact on growth and body composition. These findings emphasize the importance of early GH therapy initiation to optimize stature and reduce the risk of obesity-related complications in PWS patients. However, long-term studies are needed to further assess its metabolic benefits and potential risks.

JOINT2957

The rare co-occurence of pituitary gigantism and thrombocytopenia!

Yasmine Abdelmeguid[1]
[1]Faculty of Medicine, Alexandria University, Pediatric Endocrinology and Diabetology, Alexandria, Egypt

Background
Pituitary gigantism is a rare-yet important-disorder of GH axis leading to excessive height. It is usually due to over-secretion of GH by a pituitary adenoma occurring before epiphyseal closure. To date, several hematological diseases such as leukemia, thrombocytopenia, or Hodgkin lymphoma have been rarely reported in patients with pituitary adenoma, especially in acromegaly patients. The co-existence of the two diseases may be due to a common pathogenic mechanism or a co-incidence. However, the rarity of pituitary gigantism makes it difficult to establish the effect of elevated GH levels on platelet count.
Case Summary
A 14.75-year-old girl presented with increase in height noticed since 6 years and menorrhagia since 6 months. Her mid-parental height was 167.5 cm. Her parents were non-consanguineous and there was no family history of tall stature. At age 8 years, she was diagnosed with hypothyroidism (TSH 6.06 uIU/ml, fT4 1.59 ng/dl) , and started on L-thyroxine 50mic daily. On examination, her weight was 72kg (+1.63SD), height 187cm (+3.72SD), and BMI 20.6 (+0.18SD). Her arm span was 182cm. She had normal blood pressure, left precordial bulge with an ejection systolic murmur heard over the base of heart. She had enlarged jaw, hands and feet. She had no ecchymotic patches, purpura, or cafe-au-lait spots. Her investigations revealed thrombocytopenia (platelets 52.000) which had been persistent in previous blood counts. Her IGF-1 level was normal (256 ng/ml), however, GH suppression test by glucose load was not suppressible (least 1.14 ng/ml). Her bone age was 14 years. She had hyperprolactinemia (67 ng/ml), while her TSH was 1.64 mIU/ml, Ft4 1.48 ng/dl on L-thyroxine treatment with negative thyroid antibodies. Lupus markers were done to exclude autoimmune cause of thrombocytopenia (ANA, C_3, and anti-dsDNA) and were negative. Serum cortisol, ACTH were normal. Her MRI brain showed left-sided pituitary microadenoma (3X4mm) and echocardiography revealed wide atrial septal defect with mildly hypertrophied prolapsed mitral valve with grade II-III regurgitation. Her fundus examination was normal. She was started on cabergoline 0.25 mg twice/week, and long-acting octreotide (lanreotide) 30mg monthly to suppress GH and prevent further increase in height. L-thyroxine was stopped as investigations confirmed TSH-secreting adenoma rather than a primary thyroid disorder. Her platelet count increased after receiving octreotide.
Conclusions
Understanding the link between pituitary gigantism and thrombocytopenia may shed light into the pathophysiology of the disease and requires further studies. Hence, performing complete blood count as routine work-up in patients with pituitary gigantism is essential.

Response to recombinant growth hormone therapy in an indian girl with 3-M syndrome

Divya Pachat[1], Dhanya Soodhana[1] & Vimal M V[1]
[1]Aster Malabar Institute of Medical Sciences, Kozhikode, Department of Pediatrics, Kozhikode, India

Introduction
3-M syndrome is a rare autosomal recessive disorder characterized by short stature, distinctive facial features, and skeletal abnormalities. Mutations in the *CUL7*, *OBSL1*, and *CCDC8* genes are associated with this condition. Short stature in 3-M syndrome has been attributed to growth hormone (GH) resistance rather than GH deficiency. GH resistance has been linked to impaired protein scaffolding, transport dysfunction, and p53-mediated apoptosis in the IGF-1 post-receptor pathway. Here, we describe the growth trajectory of an Indian girl with 3-M syndrome undergoing recombinant GH therapy.
Case Report
A 4-year-old girl, born to non-consanguineous parents, was delivered at term with a low birth weight (2300 g; -2.25 SDS) and length (46 cm; -1.69 SDS). She experienced birth asphyxia and required neonatal intensive care for 13 days. Antenatal ultrasound at 34 weeks had raised the suspicion of skeletal dysplasia. At birth, she exhibited characteristic features of 3-M syndrome, including a broad, fleshy nose, anteverted nostrils, thick patulous lips, a square chin, curvilinear eyebrows without synophrys and a short thorax. Radiographic features included slender long bones with diaphyseal constriction and flared metaphyses. Vertebral bodies appeared tall with reduced anterior-posterior and transverse diameter and anterior wedging of the thoracic vertebral bodies. Her ribs appeared to be horizontal. Pelvic bones were small and the iliac wings appeared flared. She had a delayed bone age, A clinical diagnosis of 3-M syndrome was confirmed after genetic testing, which revealed a compound heterozygous class 1 and class 2 variation in the *CUL7* gene. IGF-BP3 levels were normal. We did not perform a growth hormone stimulation test as she had a genetic diagnosis. Recombinant growth hormone therapy was initiated at 3 years of age, at a dose of 35 mg/kg/day. After 1 year of treatment, a height gain of 12 cm was observed, demonstrating a significant response to GH therapy.
Conclusion
This case highlights a notable height SDS increase over one year of follow-up in a child with 3-M syndrome receiving GH therapy. Clinicians should recognize the variability in GH response among individuals with 3-M syndrome and consider early intervention when appropriate.

A paediatric case of progeroid lipodystrophy due to a de novo mutation in POLD1 gene

Sara Barneschi[1,2], Renato Vaiasuso[1,2], Matteo Cerutti[1,2], Giulia Del Medico[1,2], Eugenio Trinati[1,2], Elena Andreucci[3], Gaia Varriale[2], Stefano Stagi[1,2] & Franco Ricci[2]
[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Diabetology and Endocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy; [3]Genetic Unit, Meyer Children's Hospital IRCCS, Florence, Italy

Background
POLD1 gene encodes the catalytic subunit of the DNA polymerase delta, an enzyme essential for genome replication and repair. Pathogenic mutations in the *POLD1* gene are responsible for Mandibular Hypoplasia, Deafness, Progeroid Features, and Lipodystrophy (MDPL) syndrome, a rare autosomal dominant disorder. The key clinical features are reflected in its name, with additional manifestations including joint contractures, prominent eyes, crowded teeth, small mouth, beaked nose, poor breast development in females, insulin resistance, diabetes mellitus, abnormal liver function, and hypertriglyceridemia. Here, we describe a new paediatric case of MDPL syndrome, focusing on her clinical features.
Clinical Case
A 5-year-old girl was referred to our Endocrinology Unit for growth delay. Her medical history revealed consistently normal but below-average growth, with a deceleration over the past year. At the first evaluation, height was below the genetic target (-2.26 SDS), with a BMI indicative of severe underweight (-5.21 SDS). She exhibited distinctive phenotypic features, including hypoplastic earlobes, thin nasal bridge, short philtrum, deep bite, clinodactyly of the fifth toes, bilateral ankle joint stiffness and reduced subcutaneous adipose tissue. Blood tests performed to investigate the growth failure resulted within normal ranges, with adequate IGF-1 levels. The Bone age X-ray findings were consistent with the patient's chronological age. During follow-up, she exhibited a further decline in BMI, increased joint stiffness and reported early signs of hearing impairment, confirmed by an audiological evaluation revealing bilateral sensorineural hearing loss. Given the clinical suspicion of a lipodystrophy syndrome, whole-exome sequencing was performed, identifying a de novo *POLD1* mutation and confirming the diagnosis of MDPL syndrome. The mutation consists of an in-frame deletion (c.1812_1814delCTC) of the serine residue at position 605 of the polypeptide chain, resulting in the complete loss of DNA polymerase activity. Metabolic blood tests revealed normal serum levels of leptin, cholesterol, triglycerides and transaminases. An oral glucose tolerance test ruled out insulin resistance.
Conclusions
Our case confirms that MDPL syndrome belongs to the highly heterogeneous group of lipodystrophy disorders. Moreover, this condition should be considered in the differential diagnosis of patients with growth delay, and early-onset hearing impairment. Progressive loss of subcutaneous fat, gradually occurring in late childhood, must be a mandatory criterion for diagnostic suspicion. Early identification of the genetic mutation allows for better management of symptoms and long-term potential complications. Additionally, this case highlights the value of whole-exome sequencing in diagnosing rare genetic disorders.

Case series on growth hormone deficiency: clinical and endocrinological insights

Sandra Sanchez García[1], Vivian Morales Venegas[1], Leonor Hinojosa Amaya[1] & Rosfell Heredia Salgado[1]
[1]Universidad Autónoma de Nuevo León, Pediatria, Monterrey, Mexico

Introduction
Growth hormone deficiency (GHD) is a pediatric endocrine disorder characterized by insufficient growth hormone production, leading to impaired growth. It can be congenital or acquired, with an estimated prevalence of 1 in 4,000 to 10,000 live births. Diagnosis involves clinical history, growth analysis, biochemical tests, and neuroimaging.
Case Series
The information of 9 cases with GHD was analyzed. Of these, 77.8% were male, with an average age of 11.4 years (7-15) and an average age at deficiency diagnosis of 9.44 years (5-14). A history of short stature was present in 55.4% of these patients, and somatometric evaluation identified an average familial target height of 167.7 cm (158-174) and a height at diagnosis with an average deviation of 11.1 cm below their genetic growth channel (4-19). Only 3 patients (33.3%) had undergone well-child check-ups for at least the first 12 months of life. The diagnosis was made through the measurement of somatomedin (IGF-1), which had an average value of 101.9 ng/ml (25-262). Brain magnetic resonance imaging (MRI) was performed in 7 patients (77.8%), and of these, only 2 cases (28.6%) showed anatomical abnormalities possibly related to growth hormone deficiency. In one case, an arachnoid cyst of the pituitary gland was observed, while in the other, a Rathke's cleft cyst was identified. All patients received treatment with recombinant human growth hormone (r-hGH) at an average weight-based dose of 1.22 IU/kg/week (0.77-1.85), with good adherence to treatment. At their last follow-up visit, their average height was 133.4 cm (109-151).
Discussion
This case series analyzes the clinical features, diagnostic methods, and treatment outcomes in pediatric patients with GHD, emphasizing the heterogeneity of its presentation. Neuroimaging was crucial in identifying structural pituitary abnormalities in some cases, while family history and classic clinical presentations enabled earlier diagnosis in others. Treatment with r-hGH showed positive outcomes in growth velocity and predicted adult height. Variability in treatment response based on the underlying cause of GHD pointing out the need for individualized approaches.
Final Comments
This study highlights the importance of a multidisciplinary, personalized approach to meet each patient's needs and provides insights into the challenges of managing GHD, paving the way for future research to optimize its diagnosis and treatment.

Background
Recombinant human growth hormone (rhGH) treatment in children with idiopathic isolated growth hormone deficiency (IIGHD) typically results in catch-up growth for several years followed by a period of normal growth. The efficacy of rhGH for late pubertal height gain in adolescents with IIGHD remains unclear.
Aims
This study aimed to develop and validate a model predicting height gain (cm) from mid-puberty to near adult height (NAH; height velocity <2cm/y) in IIGHD patients who were GH sufficient upon retesting at NAH.
Methods
For model development, data from the Dutch National Registry of Growth Hormone Treatment in Children were used, focusing on 151 patients with IIGHD (98 males, 53 females) who received rhGH treatment until NAH. Participants diagnosed with IIGHD (GH peak at diagnosis 1.7-10 µg/L) received rhGH treatment for a minimum of 2.5 years. GH peak was >10 µg/L upon retesting at NAH, with treatment discontinued for at least 1 month. Mid-puberty was defined for males as Tanner stage G3-G4, testicular volume >12 ml, and bone age (BA) 13-16 years, and for females as Tanner stage B3-B4 and BA 11-14 years. If no GH retest had been conducted, we used IGF-I >0 SDS after cessation of therapy and the pediatric endocrinologist's judgment to determine GH sufficiency. Validation was done in 33 males and 7 females from the prospective SEENEZ trial.
Results
In the model, final predictors at mid-puberty included age, BA, Tanner stage, and target height (TH) SDS minus height SDS at mid-puberty. Adjusted for overoptimism the equation for males was: 82.07 - 1.41 * Tanner stage 4 or 5 - 2.55 * age – 2.36 * BA + 2.33 * (TH SDS - height SDS). R^2 was 48%, residual SD was 4.16 cm. For females: 39.85 - 0.57 * age – 1.72 * BA. R^2 was 18%, residual SD was 3.64 cm. Validation analysis showed a mean (SD) difference of 1.48cm (2.36) for males and 3.57cm (2.66) for females between predicted and attained NAH.
Conclusions
This study developed a prediction model for height gain in adolescents with IIGHD during rhGH treatment in the final stages of puberty. For females, explained variance was insufficient to reliably predict height gain. For GH sufficient males, the model can be used to assess efficacy of continuing or discontinuing rhGH treatment at mid-puberty in prospective studies and to facilitate shared decision-making regarding treatment continuation at mid-puberty.

JOINT3656

Short stature in short bowel syndrome: complex interplay between nutrition and growth

Joana Vasconcelos[1], Catarina Coelho[1,2], Beatriz Pedreira[1,3], Tânia Serrão[4], Catarina Limbert[1] & Lurdes Lopes[1]
[1]Pediatric Endocrinology Unit, Dona Estefânia Hospital, Local Health Unit of São José, Lisbon, Portugal; [2]Pediatric Unit, Local Health Unit of Leiria, Leiria, Portugal; [3]Pediatric Unit, Nélio Mendonça Hospital, Madeira, Portugal; [4]Pediatric Unit, Dona Estefania Hospital, Lisbon, Portugal

Introduction
Short bowel syndrome (SBS) is a malabsorptive condition characterized by extensive intestinal resection. In pediatric patients, SBS can significantly impair growth and development, despite aggressive nutritional support, often resulting in short stature. Growth failure in these patients is multifactorial and may include nutritional deficiencies, chronic inflammation, and hormonal dysregulation. Insulin-like growth factor 1 (IGF-1) is a critical mediator of growth hormone (GH) action, responsible for stimulating cell growth, differentiation, and skeletal development. In intestinal failure, IGF-1 deficiency could occur despite normal or even elevated levels of GH. Understanding the contribution of IGF-1 deficiency to growth failure in SBS is crucial for developing effective management strategies.
Case description
A fourth-year-old girl presented with severe short stature. She is the daughter of a non-consanguineous couple. After an uneventful pregnancy, she was born at 35 weeks by vaginal delivery; her birth weight was 2390g (-0,25 standard deviation score [SDS]) and her length was 44cm (-0,76 SDS), with no apparent physical malformations. She was diagnosed with intestinal atresia and underwent surgery

on the 2nd day of life, resulting in SBS without ileocecal valve. She underwent multiple surgeries and gastrointestinal continuity was restored. At two years and 5 months she began Teduglutide (analog to glucagon-like peptide 2) and at the age of three years and 6 months stopped parenteral nutrition. Progressive growth delay was noticed since the first months of life, with important worsening in the previous two years. In the last appointment she had a height of 85,8cm (-3,8 SDS), with target height of 170,8cm (+1,45 SDS), and weighted 12,9kg (-1,8 SDS); there were no facial dysmorphism; systemic examination was also unremarkable; the bone age was 18 months. Laboratorial investigation revealed very low IGF-1 levels [12,4ng/ml (Reference value: 77-235ng/ml); normal thyroid and liver function; her karyotype was 46,XX. A GH stimulation test was performed, yielding normal results (peak 10,50ng/ml).
Discussion
Normal weight gain with low IGF-1 and normal GH levels points to the importance of the intestine' role in the endocrine growth system. The diagnosis of secondary GH insensitivity in pediatric SBS, may allow for IGF-1 or GH replacement therapy. This case highlights the need of a multidisciplinary approach due to complex interplay between nutritional factors, and endocrine function in pediatric patients with SBS and short stature. Early recognition and targeted interventions, including optimizing nutrient absorption and addressing hormonal deficiencies, are essential to improving growth outcomes in children with chronic gastrointestinal conditions.

Comorbidities in pediatric turner syndrome: differences between 45,X0 and mosaic karyotypes

Francisca Leitão[1], Raquel Henriques[2], Brígida Robalo[2], Carla Pereira[2] & Maria de Lurdes Sampaio[2]
[1]Hospital Garcia de Orta, Almada, Portugal; [2]Unidade de Endocrinologia Pediátrica, Serviço de Pediatria Médica, Departamento de Pediatria, ULS Santa Maria, Lisboa, Portugal

Introduction
Turner syndrome (TS) is associated with several phenotypic conditions that increase the likelihood of developing various comorbidities.
Objective
This study aims to assess the prevalence of congenital malformations and the development of age-related comorbid conditions and to compare whether these are different between 45,X monosomy and mosaic karyotypes.
Methods
Retrospective cohort study of patients with TS followed in a referral pediatric center in Portugal from childhood to early adulthood (1977-2024). The karyotype, the prevalence of cardiac and renal congenital malformations, and the prevalence of subsequent specific comorbidities were evaluated, including height and weight status, thyroid disease, menstrual irregularity, developmental delay/learning disabilities and hearing loss.
Results
69 patients were followed, with a mean age at diagnosis of 5 years (+/- 5.1), and a mean age at first appointment of 8 years (+/-5.2). Of these, 41 (59%) had a 45,X0 karyotype and the remaining had various types of mosaicism. Both congenital heart and renal malformations were more frequent in 45,X0 patients, represented by 41%, (28/69) and 25%, (17/69), respectively. The incidence of subsequent acquired conditions increased with age, more markedly in 45,X monosomy, with the following prevalences: 23% (16/69) thyroiditis, with 63% (10/16) in 45X0, followed by 45X046XX in 19% (3/16); 6% (4/69) overweight/-obesity, with 50% (2/4) in 45X046XX; 12% (8/69) menstrual irregularity, with 75% (6/8) in 45X0, followed by 25% (2/8) in 45X046XX; 25% (17/69) developmental delay/learning disabilities, with 59% (10/17) in 45X0, followed by 12% (2/17) in 45X046XX; and 4% (3/69) hearing loss, with 67% (2/3) in 45X0. All patients had short stature, and 75% started GH treatment at a mean age of 9 years and 5 months. Median Turner final height SDS was 0.86(IQR = 0.54-1.49) and median SDS for general population was -2.26(IQR = -3.3—1.3). Only two patients achieved target height.
Conclusion
Our findings indicate that Turner syndrome patients with a 45,X0 karyotype exhibit a higher prevalence of both congenital malformations and age-related comorbidities compared to those with mosaic karyotypes. These results highlight the importance of tailored monitoring and early intervention based on karyotype differences to improve clinical outcomes in Turner syndrome.

Insights from IGF-1 generation test responses in growth disorders

Fawzia Alyafei[1], Ahmed Elawwa[1], Shayma Ahmed[1,2], Noor Hamed[1], Nada Alaaraj[1] & Ashraf Soliman[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Hamad Medical Corporation, Pediatric Endocrine and Diabetes, Doha, Qatar

Background
The IGF-1 generation test evaluates the ability to produce IGF-1 in response to growth hormone (GH) stimulation, providing diagnostic insights into growth disorders. The variability of IGF-1 responses across different conditions highlights its utility in differentiating underlying pathophysiological mechanisms.
Objective of the Review
To summarize findings from studies investigating IGF-1 generation test responses across diverse growth disorders and assess its diagnostic and therapeutic implications.
Material and Methods
Data were synthesized from 16 studies involving over 1,200 pediatric patients with conditions such as GHD, Idiopathic Short Stature (ISS), Small for Gestational Age (SGA), Turner Syndrome (TS), Noonan Syndrome (NS), Thalassemia Major (TM), and chronic malnutrition. Studies reviewed included IGF-1 baseline levels, post-stimulation responses, and their correlation with GH therapy outcomes.
Results
Table:
1. GHD: Patients exhibited significantly reduced IGF-1 generation, confirming GH deficiency (Ghigo *et al*., 2000; Stanley *et al*., 2015).
2. SGA: Consistently reduced IGF-1 production due to intrauterine growth restriction was noted, persisting despite GH therapy (Boguszewski *et al*., 1995; Finken *et al*., 2006).
3. Turner Syndrome: Reduced IGF-1 responses indicated partial GH insensitivity, though GH therapy improved height outcomes (Rosenfeld *et al*., 1998).
4. Chronic Malnutrition: Impaired IGF-1 production was attributed to protein-energy malnutrition, even with normal GH levels (Bozzola *et al*., 1997).
5. ISS: Normal IGF-1 generation ruled out GH insensitivity as a contributing factor (Colle *et al*., 1999; Misra *et al*., 2012).
6. Thalassemia Major: Iron overload and nutrient deficiencies impaired IGF-1 generation, affecting growth outcomes (Soliman *et al*., 2009).
7. Noonan Syndrome: Mild GH insensitivity led to a blunted IGF-1 response, with GH therapy still showing growth improvement (Binder *et al*., 2005).
Discussion
The IGF-1 generation test provides critical insights into GH sensitivity and function across growth disorders. Reduced IGF-1 generation often correlates with GH insensitivity or systemic factors such as malnutrition or iron overload. Normal IGF-1 generation, as in ISS, helps exclude GH resistance as a primary cause.
Conclusions
IGF-1 generation tests are invaluable for diagnosing and managing pediatric growth disorders. While reduced IGF-1 responses often confirm GH dysfunction or systemic impediments, condition-specific variability necessitates individualized clinical interpretations.

JOINT1263

Growth and pubertal outcomes in CHARGE syndrome: a case study of hormone replacement therapy

Bogdan Pascu[1] & Diana Taifas[1]
[1]INSMC Alessandrescu Rusescu, Pediatric Endocrinology, Bucharest, Romania

Background
CHARGE syndrome is a rare genetic disorder characterized by a spectrum of anomalies, including coloboma, heart defects, choanal atresia, growth retardation, genital hypoplasia, and ear/hearing abnormalities. It is caused by mutations in the CHD7 gene and follows an autosomal dominant inheritance pattern. One of the primary features of CHARGE syndrome is hypogonadotropic hypogonadism (HH), leading to delayed or absent puberty in both males and females. Short stature is also common, affecting 60-72% of individuals, though the underlying mechanisms remain poorly understood.
Method
We reviewed the clinical data and investigations of a Romanian patient diagnosed with CHARGE syndrome who was admitted to our hospital in February 2024.
Case description
The patient exhibited multiple features of CHARGE syndrome, including cochlear implants, surgically corrected choanal atresia, left testicular atresia, and

right testicular orchidopexy. Whole-exome sequencing (WES) identified a heterozygous pathogenic variant, NM_017780.4:c.4695C>T, in the CHD7 gene, confirming the clinical suspicion and genetic diagnosis of CHARGE syndrome in 2020. At the time of consultation, the 14-year-old patient had a significantly below-average growth trajectory, with a height of -3.01 standard deviations (SD) and a developmentally small penis (-2.5 SD). Hormonal tests revealed low levels of FSH (0.53 mUI/ml), LH (<0.03 mUI/ml), and testosterone (0.14 ng/ml), indicating hypogonadotropic hypogonadism. His Tanner stage was also inconsistent with his chronological age, further confirming the diagnosis of HH. Two years prior, the patient's growth hormone levels were normal. However, recent stimulation tests indicated growth hormone deficiency. IGF-1 values were at the lower limit (-2.09 SD). As a result, hormone replacement therapy (HRT) with somatropin and Androgel was initiated. After seven months of somatropin treatment, his height improved from -3.01 SD to -2.68 SD. However, Androgel proved ineffective, prompting a switch to testosterone enanthate in January 2025. Following this change, the patient's penile length increased to 6 cm. Additionally, autoimmune thyroiditis was detected via ultrasound during his first consultation, although his thyroid function remained normal.

Conclusions

Individuals with CHARGE syndrome commonly experience delayed or absent puberty due to hypogonadotropic hypogonadism. Hormone replacement therapy, including growth hormone and testosterone, is essential for promoting growth and inducing puberty in these patients. Early intervention can improve outcomes, particularly in terms of physical growth and sexual development.

Our experience with somatrogon: therapeutic efficacy, adult height, safety and adherence

Lidia Castro-Feijoo[1], Isabel Martínez[2], Jesús Pino[3], Begoña Vazquez[1], Roberto Tejera[1], M. Sol Rodriguez[4], Jesús Barreiro[5] & Paloma Cabanas[1]
[1]Endocrinología Pediátrica. Hospital Clínico Universitario de Santiago de Compostela. Instituto de Investigación Sanitaria de Santiago., Santiago de Compostela, Spain; [2]Cardiología Pediátrica. Hospital Clínico Universitario de Santiago de Compostela., Santiago de Compostela, Spain; [3]S. Traumatología. Hospital Clínico Universitario de Santiago de Compostela. USC., Santiago de Compostela, Spain; [4]S. Farmacia. Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, Spain; [5]Endocrinología Pediátrica. IDIS, Santiago de Compostela, Spain

Long-acting growth hormones (LAGH) constitute a therapeutic innovation in growth hormone deficiency (DGH). Its efficacy, safety, immunogenicity and bioavailability should be comparable to daily administered GH. With them it is expected to reduce the treatment burden, positively influence the quality of life of the patient and family, improve adherence and consequently therapeutic efficacy. Somatrogon, a LAGH, has been approved for use by the EMA and FDA in the child with GH deficiency.

Objectives

To evaluate the therapeutic efficacy, safety and adherence in a group of children diagnosed with GH deficiency treated with weekly LAGH (Somatrogon).

Methodology

Prepubertal patients diagnosed with GH deficiency and treated with Somatrogon. Clinical follow-up evaluating therapeutic efficacy criteria (variation of the SDS of height, relationship of height with target height, progress of bone age, puberty and adult height; safety (IGF1, IGFBP3, hormonal biochemistry, lipid and glycemic metabolism and AES) and adherence (through administration record).

Results

The follow-up during 6 years of 10 patients (2 girls and 8 boys) with GH deficiency treated with Somatrogon is presented. Five of them were initially treated with daily GH for 1 year and then continued with Somatrogon and another five from the beginning were treated with Somatrogon.

1. Therapeutic efficacy: All patients have increased their growth velocity, recovering their growth curve according to their genetic potential, with gains in height > 1SDS, with an evolution of bone age and sexual maturation according to chronological age.
2. Adult height: Four patients have reached adult height (AH), one girl with AH of 161.1 cm (SDS -0.16) and three boys with AH of 171.4 cm (SDS-0.63), 165. 7 (SDS -1.68) and 170.1 cm (SDS -0.71), respectively.
3. Safety: IGF1 levels have remained in the safe range and only in two patients, during puberty, a modification of the therapeutic dose was required. Without AES or local reactions relevant. Patients and families have expressed satisfaction with weekly administration.
4. Therapeutic adherence: It has been 100%.

Conclusions

Somatrogon (LAGH) has shown safety and efficacy in promoting linear growth in this patients group treated in our clinic. Similarly to daily GH in the treatment of GH deficiency; although with excellent adherence and less treatment burden. Four patients achieved adult height near their target height. LAGH are emerging as an innovative and safe treatment in the patient with growth hormone indication.

JOINT1312

A post market observational study to evaluate user's perception on technology acceptance and usability of two generations of digital devices to manage growth disorders across france and spain

Marie-Nathalie Castel[1], Yvonne Limpens[2], Octavio Rivera-Romero[3], Olga Rife[4], Sophie Berger[5] & Ekaterina Koledova[6]
[1]Medical Devices Quality, Global Healthcare Operations, Ares Trading SA (an affiliate of Merck KGaA, Darmstadt, Germany), Eysins, Switzerland; [2]Emergo by UL Human Factors Research and Design, Emergo Europe Consulting BV, Arnhem, Netherlands; [3]Electronic Technology Department, Universidad de Sevilla, Seville, Spain; [4]Medical Affairs Department Endocrinology, Merck S.L.U. (an affiliate of Merck Healthcare KGaA, Darmstadt, Germany), Madrid, Spain; [5]Medical Affairs Department Endocrinology, Merck Santé S.A.S. (an affiliate of Merck Healthcare KGaA, Darmstadt, Germany), Lyon, France; [6]Global Medical Affairs, Cardiometabolic and Endocrinology, Merck Healthcare KGaA, Darmstadt, Germany

Background

The Easypod® 3 auto-injector (Merck KGaA, Darmstadt, Germany) is the "third generation" of Easypod® (used to administer recombinant human growth hormone treatment [Saizen®, Merck KGaA, Darmstadt, Germany]) and represents a technological evolution of its predecessor Easypod® 2. Easypod® 3 introduces new functionalities as well as ergonomics and enhances the user interface.

Objective

To compare the technology acceptance and usability of Easypod® 3 with those of Easypod® 2.

Methods

This post market ongoing observational study included 48 valid survey responses collected from France between September 13–November 21, 2024, and Spain between November 20–December 2, 2024 (aim is to collect at least 100 complete survey responses across both countries by early April 2025). Eligible study participants were Easypod® 2 users who recently (< 6 months ago) transitioned to Easypod® 3, and who used the Easypod® 3 to administer injections for at least 2 weeks. Participants completed an anonymous online survey comprised of 25 questions related to device usefulness, ease of use and usability based on the Technology Acceptance Model (TAM, score ranged from 1–5 with 5 being the most positive response) and System Usability Scale (SUS, score range 0–100). Box design score was used to assess the facilitation of storing the device upright. Participants' satisfactions were measured using a Net Promoter Score (NPS, range -100 to +100).

Results

Overall, responses from 48 participants (France [$n = 34$] and Spain [$n = 14$]) were analysed. Participants perceived Easypod® 3 to be very useful compared to Easypod® 2 with a mean TAM rating of 4.05 (France 3.91 vs Spain 4.37), and very easy to use with a mean TAM rating of 4.21 (France 4.13 vs Spain 4.41). Usability was rated excellent for Easypod® 3. with a mean SUS score of 81.46 (France 83.9 vs Spain 75.54). Participants preferred Easypod® 3's box design for facilitating upright storage of the device with a mean rating of 3.85 (France 3.79 vs Spain 4). Overall, Easypod® 3 received a very high NPS of 65 (France 59 vs Spain 79).

Conclusions

This interim analysis suggests that users' perceptions of Easypod® 3 from both technology acceptance and usability perspectives are overall positive compared to their perceptions of its predecessor Easypod® 2. The study will continue till 100 complete survey responses across both countries are received.

JOINT2215

Neurofibromatosis type 1 revealed through growth delay: a case report

Sassi Eya[1], Hajer Kandara[1], Cyrine Rgaieg[1], Manel Jemel[1] & Ines Kammoun[1]
[1]Nutritional Institute of Tunisia, Endocrinology, Tunis, Tunisia

Introduction
Neurofibromatosis type 1 (NF-1) is one of the most common inherited disorders. Incidence of NF1 is approximately 1 in 3000 individuals globally with some variations across the globe. One of the most common endocrine disorders in NF1 are short stature with or without growth hormone deficiency. Here, we report the case of two brothers in whom GH deficiency revealed NF-1.
Case Report
The first case, an 11-year boy without medical history was referred for harmonious growth delay. Physical exam was remarkable for multiple café-au-lait spots (more than six spots) and lentigines, height and weight were less than -2DS. Biology revealed a GH deficiency and subclinical hypothyroidism. Brain MRI revealed the presence of unidentified hyperintense objects in the bipallidal and cerebellar regions without other significant anomalies. GH therapy and thyroid hormone substitution were initiated with close endocrinological surveillance. The second case, the brother a 10 years-old boy without any medical history, was referred for short stature. Physical exam revealed harmonious growth delay with height and weight were less than -2DS and cutaneous exam showed multiple café-au-lait spots and lentigines. Biology revealed a GH deficiency and subclinical hypothyroidism. Brain MRI revealed ventriculomegaly without aqueductal stenosis and showed the presence of unidentified hyperintense objects in the bipallidal and cerebellar regions. There was also a borderline-sized anterior pituitary gland, a Rathke's pouch cyst and cortico-subcortical atrophy. Ophthalmologic examination revealed the presence of Lisch nodules and Yasunari spots, a pathognomonic signs of neurofibromatosis type 1, confirming the diagnosis. GH therapy was initiated with close endocrinological and neurological follow-up.
Discussion
Short stature with or without Growth hormone deficiency (GHD) is well-known as a clinical feature of NF1, but rarely reveals the disease. The GHD is more common in children with NF1 compared to the general population. The cause of GH deficiency in NF-1 is not clear, it can be observed in intracranial tumors, due to tumor treatments or without any organic pituitary damage. Patients with NF1 are at higher risk of developing tumors than the general population, thus healthcare providers must recognize its diverse manifestations for timely diagnosis and optimal care.
Conclusion
Clinical manifestations of NF1 must be detected in the early pediatric age. Patients require frequent long-term follow-ups by several specialists for early identification of endocrinopathies, emphasizing the importance of a multi-disciplinary team approach.

JOINT3875
Short stature due to ADAMTSL2 variant as a rare cause of geleophysic dysplasia: growth hormone had no role in treatment
Muna Sharaf[1]
[1]Ibn Sina Hospital, Pediatric, Jenin, Palestine

Background
Geleophysic dysplasia is a progressive skeletal disorder that mimics lysosomal storage diseases. It is characterized by short stature, brachydactyly, progressive joint contractures, distinctive facial features (including a "happy face" with full cheeks, hypertelorism, and a prominent philtrum), progressive cardiac valvular disease, and thickened skin. Intellectual development remains normal. The disorder is inherited in an autosomal recessive manner when caused by biallelic pathogenic variants in **ADAMTSL2** or in an autosomal dominant manner when caused by heterozygous pathogenic variants in **FBN1** or **LTBP3**.
Case Presentation
We report a case series of three Palestinian sisters and their cousin, all born to consanguineous parents, presenting with short stature, brachydactyly, lordosis, and delayed bone age. Initially diagnosed with idiopathic short stature, they were treated with growth hormone (GH). Whole-exome sequencing confirmed a homozygous **c.475C>T (p.Arg159Trp)** variant in **ADAMTSL2**, resulting in abnormal protein translocation.

- **Patient 1 (20 years old):** Final height 148 cm (-2.4 SD); received GH for 2 years, discontinued at bone age 14 years.
- **Patient 2 (15 years, 10 mon old):** Final height 150.2 cm (-1.7 SD), completed puberty; received GH for 4 years until bone age 13 years, 6 months.
- **Patient 3 (10 years, 4 mon old):** Current height -2.4 SD; received GH from bone age 5 years to 10 years, with height increasing from 106 cm to 124 cm. Echocardiography revealed mild aortic stenosis.
- **Cousin (12.5 years old):** Height -3.5 SD, mid-puberty, with delayed bone age (by 1.5 years). Did not receive GH and underwent bicuspid aortic valve repair for severe stenosis.

Conclusion
Despite GH treatment, the three sisters exhibited growth patterns inconsistent with expected parental height, and the youngest demonstrated similar growth velocity before and after GH discontinuation. Their cousin, who did not receive GH, exhibited a similar phenotype. These findings suggest that GH therapy had no significant impact on final height in individuals with **ADAMTSL2-related** geleophysic dysplasia, emphasizing the need for alternative management approaches.

JOINT1830
Access to growth hormone treatment for short stature children with noonan syndrome-the experience of the Wroclaw centre, poland
Magdalena Makowiecka-Wolek[1] & Robert Śmigiel[1]
[1]Wroclaw Medical University, Department of Pediatrics, Endocrinology, Diabetology and Metabolic Diseases, Wrocław, Poland

Introdution
Noonan syndrome (NS) is a clinically heterogeneous and autosomal dominant disorder which occurs with a frequency of 1: 1000 - 1: 2500 live births regardless of gender. The most characteristic clinical features are: short stature, congenital heart defects, numerous and various dysmorphic features, as well as deformities of the chest, skeletal and urogenital system as well and coagulation disorders disturbances. Psychomotor development as well as intellectual disability may be delayed.
Aim
The aim of this study was to analyse the availability of growth hormone treatment for children with Noonan syndrome in the Lower Silesia region.
Methods
The histories of 53 children were analysed consulted at the Genetic and Endocrinology Clinics for Children of the University Clinical Hospital in Wrocław, Poland who were diagnosed with Noonan syndrome confirmed by genetic testing.
Results
Between 2000 and 2024, 53 children were diagnosed with Noonan syndrome at the Genetic Outpatient Clinic of the University Clinical Hospital in Wrocław. Treatment with rhGH was implemented in a total of 10 children (19%), in 5 of them within the framework of available drug programmes (min.: drug programme for growth hormone deficiency, SGA or IUGR), in 1 child the treatment is carried out from the parents' own resources, 4 children started treatment within the framework of a clinical trial in other centres in Poland. Nine children remain in observation - 17% (observation of growth rate with growth $>=$ 3 c, age less than 4 years). Diagnosis of possible growth hormone deficiency in 4 children is currently ongoing. No adverse effects were observed in any case of rhGH use. All children underwent a cardiology consultation with ECHO evaluation of the heart to exclude hypertrophic cardiomyopathy.
Conclusions
Despite current global data demonstrating the efficacy and safety of rhGH treatment, only a small proportion of children with NS in Poland have access to this therapy. The inclusion of a larger group of patients requires changes to the current drug programme for rhGH in Poland

JOINT849
Use of CGMS to identify early glucose changes in patients on growth hormone therapy
Steven Ghanny[1], Javier Aisenberg[1] & Rachel Siegel[1]
[1]Hackensack University Medical Center, Hackensack, United States

Introduction
Growth hormone is used to treat patients with a variety of growth disorders. A common side effect of growth hormone therapy is hyperglycemia. Monitoring for hyperglycemia in patients on growth hormone therapy is done via HbA1C. However, the exact timing of the changes in glucose levels experienced by high-risk patients on growth hormone therapy has not been widely studied. Insight into the glucose levels in these patients can help providers to manage hyperglycemia

earlier in the course of treatment. The advent of Continuous Glucose Monitoring Systems (CGMS) allows patients to be able to obtain real time glucose data at multiple time points.
Objectives and hypotheses
To use CGMS to monitor glucose levels in high-risk patients on growth hormone therapy to identify early changes in glucose levels. Also, to assess if there are differences in glucose patterns in high-risk patients on daily vs weekly growth hormone therapy.
Methods
FreeStyle Libre 3 CGM will be used to monitor glucose levels in high-risk patients on growth hormone therapy. High risk patients would be defined as patients with BMI > 86%; those with family history of Type 2 DM and those with baseline elevated HbA1C (above 5.6%). At risk patients would have a CGMS placed to monitor glucose levels. Those with noted abnormal glucose levels would then have another CGMS placed 2 months after interventions to look for improvement in glucose levels. Hba1C would continue to be monitored as per standard of care. Data will be stratified by risk factors and whether patient used daily vs weekly growth hormone.
Results
Preliminary results on a patient with family history of Type 2 DM and an increase in Hba1C from 5.7% to 6% was placed on CGMS. CGMS data showed glucose levels as high as 178 mg/dL with multiple times where the blood glucose levels were above 140 mg/dL. Data is currently being collected from additional patients on growth hormone therapy.
Conclusions
The data obtained from this study can demonstrate that the use of CGMS to monitor at risk patients on growth hormone therapy can help providers to identify changes in glucose levels earlier, allowing them to make changes in management before there are significant changes in Hba1C. It will also help to examine whether there are differences in glucose patterns in daily vs weekly growth hormone formulations. The data obtained in this study could lead to changes in the management of patients on growth hormone therapy.

Growth hormone therapy in montenegro over two decades

Maja Raicevic[1], Natasa Curovic Popovic[1] & Jelena Jovovic[1]
[1]Institute for Children's Diseases, Clinical centre of Montenegro, Podgorica, Montenegro

Background
Growth hormone (GH) therapy is widely used among children with short stature, and in Montenegro it is approved for five indications (GH deficiency (GHD), Turner Syndrome (TS), being born small for gestational age with failure to attain normal growth (SGA), Prader-Willi Syndrome (PWS) and chronic renal disease (CKD)). This study aims to present the structure and outcomes of children treated with growth hormone in Montenegro.
Methods
This cross-sectional retrospective study included children (age < 18 years) with short stature treated with GH between January 2005 and Decembre 2024, followed at the Institute for Children's Diseases, Clinical centre of Montenegro (centre of reference).
Results
A total of 221 children received GH therapy during the observed period of whom 52% ($n = 115$), were boys. Clinical indications were GHD ($n = 69$, 31.2%), SGA ($n = 123$, 55.7%), CKD ($n = 12$, 5.4%), TS ($n = 15$, 6.8%), and PWS ($n = 2$, 0.9%). Median of age at GH initiation was 9.7 years. Mean age at GH initiation based on indications were 11.8 years (± 3.7) for GHD, 8.3 years (± 3.2) for SGA, 7.0 years for CKD (± 5.4), 8.4 years (± 3.1) for TS and 5.4 years (± 1.4) for TS. Mean height SDS at baseline was -2.89 $\pm$ 0.72, comparable among all groups but worse for PWS. The youngest patient in our cohort was 17 months old, and the oldest at the GH initiation was 16.7 years. The responses after 3 years persisted (Mean height SD gai$n = 1.1 \pm 0.8$).
Conclusion
Being born small for gestational age with failure to attain normal growth is the most common indication from treatment in our country, which is inconsistent with international surveillance data, where GHD is predominant. Our results also point out the need to develop national growth charts to define appropriate birth length and weight due to gestational age.

An atypical case of a patient with prader-willi syndrome- difficult diagnostic pathway

Agnieszka Lecka-Ambroziak[1], Monika Gos[2], Aleksandra Landowska[2], Marta Smyk[2], Ewa Kalka[3] & Ewa Obersztyn[2]
[1]Institute of Mother and Child, Endocrinology Outpatient Clinic, Warsaw, Poland; [2]Institute of Mother and Child, Medical Genetics Department, Warsaw, Poland; [3]Institute of Mother and Child, Anthropology Unit, Warsaw, Poland

Introduction
Prader-Willi syndrome (PWS) is a multiorgan neurodevelopmental disease, caused by parental genomic imprinting disorder in 15q11-13 region.
Aim
We present an atypical clinical picture and diagnostic difficulties in a 5.5-year-old girl with PWS.
Case report
A girl born from GVI (2xspontanous miscarriages), by caesarean section in 35 Hbd because of IUGR and worsening of the foetal state, with birth weight 1160g (-4.9 SD), length 41cm (-2.6 SD), 8-9 points of Apgar score. She required nCPAP and feeding by a gastric tube from 5th day until 3 months of life. Results of karyotype, routine method, and aCGH were normal. At the age of 1.5 years short stature and low weight, hypotonia, strabismus, dolichocephalic shape of a head, downturned mouth corners, narrowing fingers, slight clinodactyly of the IV and V toes were observed. Silver-Russell syndrome and PWS were considered, multiloci methylation analysis (MLID) was performed, the results showed normal methylation pattern in analysed loci. At the age of 3.5 years there were still significant short stature (-5.5 SD) and low weight (-3.8 SD), head circumference -3.5 SD, BMI -2.5 SD, legs circumference asymmetry R > L. Due to the phenotype suggesting PWS, methylation analysis of 15q11-13 region was performed and showed abnormal *SNRPN* and *MAGEL2* methylation pattern, that allowed to verify the MLID result and diagnose PWS. The microsatellite sequence analysis showed chromosome 15 maternal disomy (mUPD15). Further analysis of 14 loci showed mUPD in 3, 3 alleles present in 1 locus (2 maternal, 1 paternal) and non-informative results in other loci. Additional tests revealed 1.5 year delay of bone age and normal IGF1 level. The rhGH treatment was started 4 months after the diagnosis with the increasing dose from 0.47 to 0.74 IU/kg/wk, with improved growth velocity from 4.8 to 9.6 cm/yr, muscle tone and psychomotor development. After 1.5 year height is at the level -4 SD, weight -2.7 SD, head circumference -3.1 SD, BMI -1.8 SD, appetite has not been increased. Family history revealed the patient's two older brothers have started rhGH treatment because of GHD. Due to unclear reason of deep pre- and postnatal short stature NGS examination was performed with no pathogenic/potentially pathogenic variants identified. A comparative WES study in siblings is considered.
Conclusions
Aimed molecular diagnostic tests and sometimes repeating/widening diagnostics in unclear clinical settings are needed. The results of the studies to date do not explain the cause of such significant growth retardation in our patient.

Bridging the treatment gap: growth hormone therapy for noonan syndrome in portugal

Carolina Monteiro Antunes[1], Ana Laura Fitas[2,3], Catarina Diamantino[2,3] & Lurdes Lopes[2]
[1]Hospital de Egas Moniz, ULSLO, Endocrinology Department, Lisbon, Portugal; [2]Hospital Dona Estefânia, ULSSJosé, Pediatric Endocrinology, Lisbon, Portugal; [3]NOVA Medical School - Faculdade de Ciências Médicas, Lisbon, Portugal

Introduction
Noonan Syndrome (NS) is characterized by distinctive facial features, congenital heart disease, and short stature. Clinical presentation is highly variable, often leading to delayed diagnosis, which is sometimes only confirmed when affected family members exhibit more severe manifestations. NS is a relatively common cause of short stature, which may or may not be associated with growth hormone (GH) deficiency. In Portugal, NS is not yet an approved indication for GH treatment.

Case Report
We describe a family with at least two generations affected by NS. Two siblings from a fraternal set of three were referred to a Pediatric Endocrinology consultation due to short stature and suspected NS. Their father underwent GH treatment during childhood, although the underlying etiological study is unknown, and he reached a final height of 158 cm (SDS). The index case is the eldest daughter, a 3-year-old girl born with facial dysmorphisms, astigmatism, and motor coordination difficulties. Clinical evaluation highlighted severe short stature (-3.73 SDS) and distinctive facial features, including a high forehead and low-set ears. Her 2-year-old brother presented with pulmonary valve stenosis, patent foramen ovale, scoliosis, and similarly severe short stature (-4.54 SDS), with comparable facial features. Both had normal birth measurements. Analytical studies showed low IGF-1 levels, but GH stimulation tests demonstrated an adequate response. Genetic testing, including a familial segregation study, identified a heterozygous variant in the PTPN11 gene, likely pathogenic and consistent with their phenotypes. Since neither case presented a confirmed GH deficiency, GH therapy is not currently approved, and both children remain under periodic follow-up.
Discussion
NS is associated with short stature in approximately 50-70% of cases, either due to GH deficiency or dysfunction of the GH/IGF-1 axis. In this family, the father was unaware of his diagnosis, likely due to mild clinical manifestations aside from short stature. Given that NS is primarily inherited in an autosomal dominant manner, parental genetic testing is crucial for identifying other potentially affected relatives. As with Turner Syndrome, early initiation of GH therapy appears to improve final height outcomes. However, in Portugal, GH treatment is not yet approved for children with NS without confirmed GH deficiency. Considering the significant impact of short stature on future well-being, it is imperative that this indication grants approval for fully reimbursed GH treatment in our country.

Genotype-phenotype correlation of endocrine comorbidities in turner syndrome

Imen Hallouli[1], Nassim Ben Hadj Slama[1], Ghachem Aycha[1], Lamys Abbes[1], Ghada Saad[1] & Yosra Hasni[1]
[1]Farhat Hached University Hospital, Endocrinology, Sousse, Tunisia

Background
Turner syndrome (TS) is a female genetic disorder that affects approximately 1 in every 2,000 baby girls. Genotypically, it can be classified based on karyotype, such as monosomy, abnormal X chromosome, and mosaics.
Objective
To study the genotype-phenotype correlations of endocrine comorbidities in adult TS patients.
Patients and Methods
A retrospective descriptive study of patients with TS followed at the University Hospital Center in Sousse. Data analysis was performed using SPSS23 software and non-parametric tests.
Results
A total of 33 patients with a mean age of 25.6 ‡ 10.6 years were enrolled. Chromosomal abnormalities were categorized as monosomy X in 54.4%, structural abnormality alone in 18.2%, and monosomy with structural abnormality in 27.3%. The age at diagnosis of TS was 16.52 # 5.71 years for patients with homogeneous chromosomal abnormalities and 16.16 ‡ 7.81 years for those with mosaic abnormalities. Schooling was more advanced in mosaic patients. Statural delay was slightly more frequent and more severe in patients with homogeneous anomalies, though no statistically significant difference was found ($P = 0.61$). The age of onset of premature ovarian failure was higher in mosaic patients (19.50 vs. 17.37 years), with no statistically significant difference compared to patients with homogeneous anomalies ($P = 0.14$). In the case of mosaicism, diabetes mellitus was more frequent (type 2 in all patients), with a later age of onset (23.67 vs. 17.50 years). Obesity was equally distributed between the two groups. The homogeneous chromosomal anomaly was more likely to cause frank hypothyroidism than other anomalies ($P = 0.04$).
Discussion
TS patients present different karyotypes, including monosomy, mosaicism, and abnormal X chromosomes. Karyotype variations might affect the phenotype of TS according to the type of chromosomal abnormality. Chromosomal analysis for all suspected cases of TS should be promptly performed during childhood to facilitate the establishment of an appropriate management plan early in life.

JOINT2044

Role of molecular investigation for diagnosing short stature: a case report of a variant in the COL9A3 and UBA5 genes

Renata Pinto[1], Maria Luiza GonçAlves[2] & João Vitor da Silva[2]
[1]Federal University of Goiás, Goiânia, Brazil; [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Introduction
Eighty percent of the height variation is explained by genetic factors, even though the standard medical evaluation of short stature (SS) relies upon physical examination and laboratory parameters and identifies a pathological cause of SS in 1–40% of individuals. This research aims to report a clinical case of a child with SS who underwent molecular investigation.
Case Report
HAS, 9 years 9 months, only daughter of a non-consanguineous couple, sought the pediatric endocrinology service complaining of SS. The child was a newborn with adequate weight and height for gestational age, with a slow growth speed from the second year of life. On physical examination, she presented: weight 18.5kg (-3.2SD), height 120cm (-2.64SD), syndromic features characterized by microcephaly (PC 45cm), epicanthus, broad nasal base, pointed and low-set ears and tooth agenesis. General laboratory tests were unremarkable; the Clonidine stimulation test was responsive (9 ng/ml), and bone age was 8 years and 10 months. A Generation Sequencing Panel for the complete exome was carried out, which showed a variant of uncertain significance (VUS) in heterozygosity in the *COL9A3* and *UBA5* genes. She started using GH at the age of 10 years 9 months, and at 11 years 11 months, she weighed 24.8 and had a height of 136.5 (-2.07SD), still without puberty signs and with normal intelligence.
Discussion
The *COL9A3* gene encodes one of the three alpha chains of Type IX collagen. Patients with variants in homozygous present with Stickler syndrome, characterized by midface hypoplasia, myopia, hearing loss, and epiphyseal abnormalities. Patients with heterozygous mutations are reported to have multiple epiphyseal dysplasia type 3. The *UBA5* gene encodes Ubiquitin-Like Modifier Activating Enzyme 5. Mutations in this gene can cause developmental and epileptic encephalopathy 44, which presents with the following symptoms: short stature, microcephaly, visual impairment, mental and motor impairment, seizures, and cerebellar atrophy. The conjunction of the two VUS in the aforementioned genes may justify the unique clinical case of this patient and was essential for the report that convinced the government of the state of Goiás to make GH treatment available to this child. Furthermore, the molecular diagnosis in cases of SS can end the diagnostic workup for the patient, it may alert the clinician to other medical comorbidities for which the patient is at risk, and it is extremely valuable for genetic counseling.

Growth hormone treatment in children with growth hormone deficiency: searching for predictors affecting adult height

Lukas Kavciak[1], Shenali Amaratunga[1], Petra Dusatkova[1], Klara Maratova[1], Dana Zemkova[1], Stanislava Kolouskova[1], Barbora Obermannova[1], Marta Snajderova[1], Zdenek Sumnik[1], Jan Lebl[1], Stepanka Pruhova[1] & Lukas Plachy[1]
[1]Department of Pediatrics of Second Faculty of Medicine Charles University in Prague and Motol University Hospital, Prague, Czech Republic

Introduction
Growth hormone (GH) stimulation tests that are used as a golden standard for diagnosis of GH deficiency (GHD) are known to have poor reliability. Children with diagnosed GHD are therefore believed to have heterogeneous etiology of their short stature and consequently heterogeneous response to GH treatment. The aim of the study was to analyze the response to GH therapy in a single center cohort and to search for the factors predicting treatment outcomes.
Methods
Children treated with idiopathic GHD in our center that achieved their final height in years 2022-2024 were enrolled to the study. The diagnosis of GHD was made according to the current guidelines, maximal stimulated concentration of GH (GH_{max}) <10 mg/l in both clonidine and insulin hypoglycemia tests were used to confirm the diagnosis. To search for factors affecting response to GH treatment, correlation analysis and ANOVA Kruskal-Wallis test were used for continuous

and categorical variables, respectively. P-values <0.05 were considered significant.
Results
In total, 138 children diagnosed with GHD and available final height were enrolled to the analysis. At GH treatment initiation, their median age was 6.1 years (IQR 4.1-7.8 years), height-SDS -2.8 (-3.2 to -2.5), IGF-1-SDS -1.5 (-1.8 to -1.1) and GH_{max} 5.9 (4.5-7.6) mg/L. Sixteen children had combined pituitary hormones deficiency (CPHD), 11 anterior pituitary hypoplasia and 26 more severe abnormal cerebral midline anatomy on MRI. The children were treated with GH for 8.8 (7.2-10.6) years with an average dose 31 (24-33) mg/kg/day. The height SDS increased by 1.3 (0.8-1.9) SD to an adult height -1.5 (-2.1 to -0.9) SD. The height SDS improvement showed a weak correlation with maximal stimulated GH concentration (correlation coefficient [CC] -0,21; $P = 0.014$). Children with GH_{max} <3 mg/L showed better height SDS improvement compared to those with GH_{max} ≥ 3 mg/L (2.3 vs 1.3 SD, $P = 0.008$), but, interestingly, no correlation between GH_{max} and height SDS improvement was found in children with GH_{max} >3 mg/L (CC 0.06, $P = 0.51$). Furthermore, height SDS gain weakly correlated with pre-treatment IGF-1 concentration (CC -0,24; $P = 0.006$) and was higher in children with CPHD ($P = 0.0009$). No correlation between effect of GH treatment and birth parameters, parents' height and brain MRI was found.
Conclusions
Height outcomes following GH treatment in children with idiopathic GHD had great interindividual variability. Better treatment outcomes were associated with lower GH_{max} and pre-treatment IGF-1 concentration and presence of CPHD. No correlation between height improvement and GH_{max} beyond 3 mg/L was observed.

Enhancing paediatric care: insights from healthcare professionals on the quality and usability of digital devices in a participatory workshop in Korea

Se-Rin Oh[1], Octavio Rivera-Romero[2], Hyun Wook Chae[3] & Ekaterina Koledova[4]
[1]Merck Ltd, Seoul, South Korea, an affiliate of Merck KGaA, Darmstadt, Germany; [2]Electronic Technology Department, Universidad de Sevilla, Seville, Spain; [3]Department of Paediatrics, Yonsei University College of Medicine, Seoul, South Korea; [4]Global Medical Affairs, Cardiometabolic and Endocrinology, Merck Healthcare KGaA, Darmstadt, Germany

Background
Integration of digital health technologies with growth hormone therapy (GHT) has transformed the care and management of paediatric patients with growth hormone deficiency (GHD). Digitalisation of healthcare systems has improved patient adherence and facilitated more effective therapeutic monitoring and support from healthcare professionals (HCPs), which are vital to patient care.
Aim
This study aimed to assess the perceived quality of digital health devices used to support paediatric GHT and evaluate the perceptions of HCPs regarding the evolution of health device technologies.
Method
A participatory workshop was conducted on 10 November 2023 in Seoul, Republic of Korea, to explore the perceptions of HCPs regarding digital health devices for paediatric GHT. Two case studies were conducted using two sample devices: Easypod® autoinjector and Easypod® connect transmitter (EP2) and its successor—Easypod® next generation (EP3). The HCPs were allowed to interact with both devices. The workshop comprised of five phases that addressed device ergonomics, configuration tasks and facilitated discussions on dimensions of the quality of an mHealth solution such as usability, safety, and perceived usefulness. Participants identified the strengths and weaknesses of the devices, providing valuable insights into the evolution of health device technology and its impact on paediatric care.
Results
The HCPs believed that the evolution of mHealth technology has positively impacted the perceived quality of digital health. Ergonomics was indicated as a crucial factor in device quality and acceptance. The HCPs favoured EP3 over EP2 because of its improved dimensions, larger screen, and better button design. EP3 was considered more suitable for paediatric patients due to its automatic data transmission features, which allows personalised treatment and improves patient adherence. Although both EP2 and EP3 were considered easy to use, EP3 was preferred because of its superior user interface, skin sensor, and monitored dosing, which tracks the injections performed and the set dose, thereby preventing drug wastage. Additionally, EP3 received positive feedback for its safety and security features and was considered like current smartphones in terms of usability. Discussions also covered the content, engagement, support, and technological evolution of devices used in paediatric GHD management.
Conclusion
The outcomes of this workshop highlight the significance of technological advancements in the management of paediatric GHD. The HCPs acknowledged that the digitalisation of GHT would benefit their clinical practices, optimise resources, and personalise care for paediatric GHD including patient preferences and self-management. This will also enhance HCP-patient communication, thereby improving adherence and patient-caregiver satisfaction.

Efficacy and safety of three-years growth hormone treatment in girls with turner syndrome and growth hormone deficiency: a case-control study

Rosario Ferrigno[1], Daniela Cioffi[1], Valeria Pellino[1], Maria Cristina Savanelli[1], Deborah Veneruso[1] & Antonella Klain[1]
[1]AORN Santobono-Pausilipon, UOSD di Endocrinologia e Auxologia, Naples, Italy

Turner Syndrome (TS) is a chromosomic disorder characterized by specific clinical features, including short stature. In these patients, recombinant growth hormone (GH) treatment is recommended, showing positive effects on growth rate, with good tolerability. However, growth outcome in TS is reportedly impaired compared with other GH-treated girls, as GH deficiency (GHD) girls. The aim of the study was to compare the growth outcome and the safety of three-years GH treatment in TS and GHD girls. The study 20 girls, 10 with TS (four X0, 40%; six mosaicism, 60%) and 10 with isolated GHD, matched for age (range: 4.17-10.42 years; median: 6.8 $\pm$ 2.37) treated with GH (starting dosage: 33.08 $\pm$ 4.31 mg/kg/day in TS girls and 32.17 $\pm$ 2.51 mg/kg/day in GHD girls) for at least 36 months. Growth parameters, glycemic profile, and IGF-1 levels were collected every six months. Compared to baseline, both TS and GHD children showed a significant improvement in height, weight, and growth rate after two years of GH treatment ($p \leq 0.01$), already evident after six months ($p \leq 0.016$). Noteworthy, patients in both groups showed a constant, significant improvement in height until 24 months, as a significantly increase was observed both after 12 months compared to six months ($p \leq 0.008$) and after 24 months compared to 12 months ($p \leq 0.031$), whereas only GHD girls showed a significant increase after 36 months compared to 30 months ($P = 0.035$). Comparing the two study groups, TS girls showed a lower height and a lower height increase throughout the study, but these differences reached statistical significance only after six and 12 months (T6: $+0.42 \pm 0.23$ SDS in TS vs $+0.74 \pm 0.38$ SDS in GHD, $P = 0.045$; T12: $+0.59 \pm 0.34$ vs $+0.93 \pm 0.39$ SDS in GHD, $P = 0.034$). Considering safety profile, treatment was well tolerated, as the most frequently reported adverse event was autoimmune thyroiditis (two TS girls, 10%); no hyperglycemia occurred throughout the treatment, whereas one TS girl (5%) and one GHD girl (5%) experienced transient hypertransaminasemia and hypercholesterolemia, respectively. In conclusion, GH treatment in both TS and GHD girls is an effective, safe treatment for short stature, improving both height and growth rate, especially during the first year of treatment. Moreover, although growth outcomes were significantly better in GHD girls in the first year of treatment, over time no significant differences were observed between TS and GHD girls

JOINT2549

Juberg-Marsidi syndrome coexisting with multihormonal hypopituitarism - a case report

Agnieszka Zubkiewicz-Kucharska[1] & Robert Śmigiel[1]
[1]Wrocław Medical University, Department of Pediatric Endocrinology, Diabetology and Metabolic Diseases, Wrocław, Poland

Juberg Marsidi syndrome (ORPHA:93972) is a rare X-linked recessive disorder characterized by severe intellectual disability, growth failure, sensorineural deafness, and hypogonadism. The full picture of the syndrome is revealed in men, but in the presence of a heterozygous variant of the *HUWE1* gene in women, the symptoms may be milder. The case of a three-year-old girl who, in addition to with Juberg-Marsisi syndrome and panhypopituitarism was described in presented report. The child was born from 1st pregnancy, complicated by threatened miscarriage, born prematurely at 33 weeks' gestation, with a body weight of 1860 g. The adaptation period was complicated by bleeding into the lateral ventricles. Psychomotor development was delayed, which was explained by prematurity and initially increased, followed by decreased muscle tone. At the age of 10 months, due to delayed psychomotor development, the girl was consulted by an endocrinologist for the first time. Secondary hypothyroidism was diagnosed and treatment with levothyroxine was initiated. The physical

examination revealed significant growth deficiency, global decreased muscle tone, abnormal body proportions in the form of shortened long bones of the limbs, small feet, varus deformity of the lower legs, as well as dysmorphic facial features: high forehead, hypotelorism, small palpebral fissures, and flat nasal bridge. There was a history of patent foramen ovale. The hearing test was normal. Despite the girl's multi-profile intensive rehabilitation and satisfactory correction of thyroid function, a significant delay in psychomotor development is still observed (the child still does not walk at the age of three years, has started crawling, sits up independently from about 24 months of age), and speech development is significantly delayed (speaks single syllables). Episodes of "suspension" were observed in the child, especially during prolonged fasting. The glycemic profile showed glucose concentrations <60 mg/dl several times. Adrenal function was normal. The girl was diagnosed with somatotropin hypopituitarism and treatment with growth hormone was requested. In summary, the girl, apart from the symptoms of the genetic syndrome, presented typical symptoms resulting from multihormonal hypopituitarism, which should result in an early diagnosis of pituitary function and implementation of appropriate treatment. Treatment with growth hormone in a child with somatotropin hypopituitarism and co-occurring decreased muscle tone may contribute not only to the promotion of growth, but also to increased muscle strength.

Circulating IGF-1 levels and trends in response to daily and weekly gh therapies: a comparative analysis

Fawzia Alyafei[1], Ahmed Elawwa[1], Shayma Ahmed[1], Noor Hamed[1], Nada Alaaraj[1] & Ashraf Soliman[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Insulin-like growth factor 1 (IGF-1) is a key marker of growth hormone (GH) activity, with its levels reflecting the efficacy and safety of GH therapies. Daily recombinant human GH (rGH) therapy provides steady IGF-1 levels, whereas long-acting weekly GH formulations (e.g., somapacitan, TransCon GH) show dose-dependent, cyclical IGF-1 responses. Understanding these patterns is crucial for optimizing treatment efficacy and safety.
Objective
To compare IGF-1 trends and cycles associated with daily and weekly GH therapies in terms of their patterns, peaks, and overall exposure (AUC).
Methods
Data were synthesized from eight studies analyzing IGF-1 response to various GH therapies, including daily rGH and weekly long-acting formulations such as somapacitan, PEG-rhGH, TransCon GH, and Nutropin Depot. Key metrics included IGF-1 levels before and after treatment, trends in weekly cycles, and AUC comparisons.
Results
• Weekly GH Therapies: Studies on somapacitan, TransCon GH, and PEG-rhGH demonstrated dose-dependent increases in IGF-1 levels, with a distinct cyclic pattern characterized by peaks around day 3-4 post-injection and gradual declines by day 7. These therapies maintained IGF-1 levels within the normal range and were associated with sustained efficacy and safety over long-term use-(Sävendahl *et al*., 2020; Chatelain *et al*., 2017).
• Daily GH Therapies: Daily rGH therapy (e.g., Genotropin, Norditropin) resulted in more consistent IGF-1 levels with minor daily fluctuations, providing a steady profile throughout the week-(Lundberg *et al*., 2018).
• Comparison of AUC: Weekly GH therapies exhibited a higher IGF-1 AUC due to pronounced peaks, while daily GH therapy maintained lower but more consistent IGF-1 levels. The higher AUC in weekly therapies indicates greater overall IGF-1 exposure, potentially enhancing efficacy but requiring careful monitoring to prevent side effects.
Discussion
Weekly GH therapies offer convenience and adherence benefits through reduced injection frequency while maintaining effective IGF-1 levels. However, the cyclic IGF-1 patterns and higher AUC necessitate careful patient monitoring to minimize risks associated with IGF-1 peaks. Daily rGH provides a stable IGF-1 profile, facilitating better fine-tuning, but at the cost of daily injections.
Conclusion

Table 1. IGF-1 Trends and Patterns Between Daily Vs Long-Acting-GH Therapies

GH Therapy Type	Key IGF-1 Trends	IGF-1 Patterns	IGF-1 Response Consistency
Daily GH	Variable-Timing, Stable Long-Term	Fluctuates-Daily	Higher consistency across days
Long-Acting GH	Dose-Dependent, Sustained Weekly	Weekly-Peaks and Troughs	Higher overall AUC due to peaks

Both weekly and daily GH therapies effectively elevate IGF-1 levels, with distinct advantages and limitations. Weekly formulations optimize patient adherence and long-term exposure, whereas daily rGH ensures consistent IGF-1 profiles.

Myhre syndrome – it is never too late

Eva Vitariusova[1], Katarína Poláková[2], Lucia Grűnnerová[3], Ludmila Koštálová[1] & Zuzana Pribilincová[1]
[1]Department of Pediatrics Comenius University Medical School in Bratislava and National Institute of Children's Diseases, Bratislava, Slovakia; [2]Outpatient Department of Pediatric Endocrinology and Diabetology and Metabolism and Nutrition Disorders, Trnava, Slovakia; [3]Institute of Medical Biology, Genetics and Clinical Genetics, Faculty of Medicine and University Hospital Bratislava, Comenius University, Bratislava, Slovakia

We present the case of a rare genetic disorder in a male patient that developed over a span of 10 years. The patient was a child of a pathological pregnancy due to intrauterine growth restriction, born small for gestational age at the 35th gestation week (1970 g, 41 cm). He underwent cardiac surgery for aortic coarctation at 5 months of age, and orchiopexy at 20 months. He was transiently treated for subclinical hypothyroidism. Subsequently, a euthyroid state was achieved without the need for further medication. He is still under regular follow-up with a neurologist, urologist, ophthalmologist, and cardiologist. Due to joint contractures in the lower limbs, botulinum toxin injections were administered. Genetic counseling was first performed in early infancy (1.5 years old), confirming a normal male karyotype and exclusion of SHOX gene defects, as well as genomic imbalances. The diagnostic process was paused for several years, during which he was referred to a pediatric endocrinologist at our center, at the age of 8.5 years. Physical examination revealed significant growth retardation (height SDS -2.7), facial dysmorphism, shortened limbs and digits, skin stiffness with gross motor limitations, normal cognitive and speech development, no pubarche and adrenarche, and bilateral testicular volume of 5 mL. The criteria for growth hormone therapy as a small for gestational age (SGA) child without catch-up growth were met, and recombinant growth hormone (rGH) treatment was initiated (dose of rGH 0.035 mg/kg/day). Given the pronounced phenotype, re-evaluation of genetic counseling was conducted. Subsequent analysis identified a de novo heterozygous mutation in the SMAD4 gene (c.1499T>C; p.Ile500Thr), which is pathogenic and causal for Myhre syndrome. SMAD4 is recognized as a tumor suppressor gene, and its mutations which are presumed to result in a gain of function are associated with Myhre syndrome. To date, no systematic studies have assessed the use of supraphysiological doses of growth hormone (SGA indication) in this specific group, moreover there is a lack of evidence that there is a consistent increase in height velocity by using rGH. Based on current knowledge, we considered rGH therapy inappropriate due to its potential anabolic effects, which may interact with SMAD4's function, and thus, treatment was immediately discontinued. Myhre syndrome is a rare, multisystemic connective tissue disorder with no specific treatment. We emphasize the importance of ongoing genetic counseling in cases of clustering pathological signs and the need for re-evaluating therapeutic approaches based on the latest evidence and interdisciplinary collaboration.

Short stature and treatment in KBG syndrome: a case report

Elif Tuğçe Tunca Küçükali[1], Mehmet Ali Oktay[1], Aylin Kılınç Uğurlu[1], Esra Doger[1], Gülsüm Kayhan[2], Mahmut Orhun Çamurdan[1] & Aysun Bideci[1]
[1]Gazi University Faculty of Medicine Hospital, Department of Pediatric Endocrinology, Ankara, Türkiye; [2]Gazi University Faculty of Medicine Hospital, Department of Medical Genetics, Ankara, Türkiye

Introduction
KBG syndrome is a rare autosomal dominant disorder characterized by specific craniofacial features (triangular face, macrodontia, a single upper central incisor), short stature, and skeletal abnormalities. The condition is caused by heterozygous mutations or deletions in the ANKRD11 gene. Herewe present a case of a patient diagnosed with KBG syndrome, monitored in our clinic due to short stature.
Case Report
A 9-year-9-month-old male patient presented to our clinic with short stature. His history revealed a birth weight of 2450 grams at 35 weeks of gestation. Short stature was noticed from six months of age. He had been followed by pediatric gastroenterology due to recurrent vomiting, which resolved after a diagnosis of

cholelithiasis and subsequent cholecystectomy. Parental consanguinity was noted. The mother's height was 150.9 cm, and the father's height was 168 cm (mid-parental height: 165.9 cm). The patient's physical examination showed a weight of 21 kg (-2.59 SD), height of 120 cm (-2.79 SD), and BMI of 14.5 (-1.29 SD). He exhibited atypical facial features (triangular face, long philtrum), macrodontia and Tanner stage 1 puberty. Laboratory findings included IGF-1 at 140 ng/ml (0/+1 SD), IGFBP-3 at 3817 ng/ml (+1/+2 SD), normal thyroid function tests, negative celiac antibodies and a bone age of 6 years and 6 months. The patient was monitored for growth velocity. At 10 years and 8 months of age, he entered puberty, with a pubertal growth velocity of 5.2 cm/year. A growth hormone stimulation test revealed a peak response of 11.2 ng/ml. Genetic testing confirmed KBG syndrome by identifying a heterozygous c.5273_5274dup variant in the ANKRD11 gene, consistent with the patient's atypical facial features, macrodontia, and short stature. Due to inadequate pubertal growth and short stature, somatropin therapy was initiated. Growth velocity improved to 7.7 cm/year with treatment. At his last follow-up (15 years and 9 months), his chronological age was 15 years and 9 months, height age was 12 years and 8 months, bone age was 15 years, weight was 47.1 kg (-2.14 SD), height was 156.9 cm (-2.36 SD), and his pubertal examination corresponded to Tanner stage 4.

Discussion/Conclusion

Short stature is a common feature of KBG syndrome, and achieving target height is rare in affected individuals. Growth hormone therapy may be effective in patients with KBG syndrome presenting with significant prepubertal short stature, even in the absence of growth hormone deficiency. However, larger-scale studies are needed to evaluate treatment efficacy and safety comprehensively.

Serum levels of intact and total IGFBP-4, and stanniocalcin-2 in congenital isolated gh deficiency

Viviane Campos[1], Manuel H. Aguiar Oliveira[1], Martin Bidlingmaier[2], Kevin CJ Yuen[3], Roberto Salvatori[4], Carla R. P. Oliveira[1], Angela Leal[1], Enaldo Melo[1], Katharina Schilbach[2], Jan Frystyk[5] & Júnia Ribeiro de Oliveira Longo Schweizer[2]

[1]Federal University of Sergipe, Aracaju, Brazil; [2]Ludwig-Maximilians-Universität in Munich, Munich, Germany; [3]University Arizona College of Medicine, Phoenix, Phoenix, United States; [4]Johns Hopkins University, Baltimore, United States; [5]University of Southern Denmark, Odense, Denmark

The Itabaianinha cohort is composed of subjects with a homozygous *GHRH-R* c.57 + 1G →A mutation, causing congenital isolated GH deficiency (IGHD). These subjects exhibit severe short stature, central obesity, hypercholesterolemia, but no premature atherosclerosis, and normal lifespan. They have marked reductions in serum IGF-I, IGFBP-3 and ALS, but normal IGFBP-1 and IGFBP-2 levels. Stanniocalcin-2 (STC2), plasma pregnancy-associated protein A (PAPP-A) and IGFBP-4 are functionally related proteins that in concert regulate IGF-I action, and hence body growth. PAPP-A cleaves IGFBP-4 enzymatically, and liberates bound IGF-I, whereas stanniocalcin-2 inhibits PAPP-A. These proteins have not previously been characterized in GH deficiency, Here, we present data on total and intact IGFBP-4 and Stanniocalcin-2. Table 1 shows that levels of intact IGFBP4 are 4-times higher in IGHD ($P < 0.0001$), with a very large effect size (Mann Whitney Eta-squared = 0.539 and a Cohen's d = 2.165), whereas total IGFBP-4 (intact plus fragments) and STC2 are similar to age- and BMI-matched controls. The higher levels of intact IGFBP-4 suggest a role of PAPP-A in mediating IGFBP-4 cleavage, which contributes to the growth reduction in this cohort

Table 1. Clinical and biochemical data in 23 IGHD individuals and 11 controls. Data are expressed as mean (standard deviation), except for glucose, insulin, triglycerides, IGF-1, IGFBP3, and intact IGFBP4 expressed as median (interquartile range)

Parameters	IGHD	Controls	95% CI	P
Age (years)	50.8 (13.7)	44.9 (15.6)	-4.8 to 16.6	0.273

The significance of cardiac MRI in transition care for Turner Syndrome: a prospective study

Małgorzata Więcek[1], Zbigniew Olczak[2], Ewa Błaszczyk[1], Małgorzata Wójcik[3], Artur Mazur[4], Magdalena Machnikowska-Sokołowska[2], Jerzy Starzyk[3], Jacek Kusa[5] & Aneta Gawlik-Starzyk[1]

[1]School of Medicine in Katowice, Medical University of Silesia, Department of Pediatrics and Pediatric Endocrinology, Katowice, Poland; [2]Medical University of Silesia, University Hospital no. 6, John Paul II Upper Silesian Centre for Child Care, Division of Diagnostic Imaging, Department of Radiology and Nuclear Medicine, Katowice, Poland; [3]Chair of Pediatrics, Pediatric Institute, Jagiellonian University Medical College in Kraków, Department of Pediatric and Adolescent Endocrinology, Kraków, Poland; [4]Medical Faculty, University of Rzeszów, Department of Pediatrics, Pediatric Endocrinology and Diabetes, Rzeszów, Poland; [5]Medical University of Silesia, Department of Pediatric Cardiology, Katowice, Poland

Background

Turner Syndrome (TS) is associated with cardiovascular abnormalities, including bicuspid aortic valve (BAV), coarctation of the aorta (CoA), and aortic dilatation, increasing the risk of life-threatening complications such as aortic dissection. Continuous cardiac monitoring is essential, particularly during the transition to adult care. While transthoracic echocardiography (ECHO) is widely used, it has limitations in assessing aortic valve morphology. Current guidelines recommend cardiac MRI for comprehensive evaluation when general anesthesia is unnecessary.

Objective

This study evaluates the role of cardiac MRI in detecting cardiovascular abnormalities in TS patients before transition to adult care, identifying undiagnosed defects, and aiding risk stratification.

Methods

This prospective study (Sep/2020 – Jan/2025) recruited TS patients from southeastern Poland. Inclusion criteria were confirmed TS diagnosis, ability to undergo MRI without anesthesia, and informed consent. Exclusion criteria included contraindications to MRI or lack of consent. Cardiac MRI (1.5T scanner with contrast) assessed aortic dimensions, left heart parameters, and congenital heart defects. Aortic dilation was evaluated using the aortic height index (AHI), aortic size index (ASI), and TS-specific Z-scores.

Results

A total of 40 TS patients with mean (min-max) age 16.2 ± 1.4 (11.7-18.0) years were included. Among them, 9 (22.5%) had a 45,X karyotype, and 31 (77.5%) non-45,X variations, 6 (15%) were overweight, 10 (25%) had obesity. Medical history revealed BAV in 6 (15%) patients, one (2.5%) with CoA. Other singular cases included persistent left superior vena cava, mitral insufficiency, aortic stenosis, and left subclavian artery widening. 10 (25%) had arterial hypertension. MRI detected BAV in 13 (32.5%), patients post-CoA in 1 (2.5%), great vessel anomalies in 4 (10%), and partial anomalous pulmonary venous return (PAPVR) in 3 (7.5%). Additional single cases included a right coronary artery aneurysm, persistent left superior vena cava, mitral annular disjunction, atrial septal defect, mitral insufficiency, and left subclavian artery widening. Aortic dilatation was found in 5 (12.5%) patients, BAV was diagnosed in 4 of them. None of them had aortic hypertension. Differences in AHI, ASI, and TS-specific Z-scores for ascending aorta dimension between BAV and non-BAV patients were not statistically significant ($P = 0.054$, 0.12, 0.07, respectively). No significant differences in congenital defect prevalence were found between 45,X and other karyotypes ($p > 0.05$).

Conclusion

The high rate of (un)diagnosed CV-pathies supports integrating MRI with routine ECHO for early detection and intervention. Strengthening transition protocols and increasing awareness of cardiovascular risks in TS could improve outcomes.

Effects of gonadotropin-releasing hormone analog, alone and in combination with recombinant human growth hormone, on height in girls with early puberty across age groups

Hasan Eida[1], Mahmoud Yousef[1], Elias Amarneh[2], Ghidaa Shareef[2], Alfarouq Alboom[2], Yasmeen Makharza[2] & Mohammed Khwaira[2]
[1]Palestinian Medical Complex, Al-Quds Unvesity, Pediatric Endocrinology, Ramallah, Palestine; [2]Alquds Unversity, Pediatric Endocrinology, Pediatrics, Ramallah, Palestine

Background
Central precocious puberty (CPP) is the early activation of the hypothalamic-pituitary-gonadal axis, resulting in the onset of puberty in girls before 8 years of age. GnRH analog therapy is commonly used to delay puberty, but it often leads to height suppression and metabolic changes. Growth hormone (GH) supplementation is sometimes added to improve final adult height, but its effect on weight and body mass index (BMI) is not well understood. This study aims to evaluate the impact of GnRH analog therapy vs GnRH analog therapy combined with GH on final height, weight, and BMI in girls with CPP.
Methods
This retrospective cohort study was conducted at Ramallah Governmental Hospital, Palestine, from 2020 to 2023, including 56 girls diagnosed with CPP before the age of 8. The patients were divided into two groups: one group received GnRH analogs only ($n = 29$), and the other received GnRH analogs with GH therapy ($n = 27$). They were further categorized into prepubertal (0–8 years), early pubertal (8.1–11 years), and mid-pubertal (11.1–14 years) subgroups. Data on height, weight, BMI, Tanner stage, and hormone levels were collected. Statistical analysis was performed using SPSS version 20, and the independent samples t-test was used for comparison, with statistical significance set at $P < 0.05$.
Results
Both groups experienced significant increases in height after treatment. The mean height in the GnRH analog group increased from 122.31 $\pm$ 10.45 cm to 145.84 $\pm$ 12.24 cm, while the combination therapy group increased from 111.81 $\pm$ 10.37 cm to 136.96 $\pm$ 11.67 cm. Weight gain occurred in both groups, but it was more pronounced in the GnRH analog-only group (from 26.12 $\pm$ 5.44 kg to 39.36 $\pm$ 6.04 kg) compared to the combination therapy group (from 19.84 $\pm$ 6.05 kg to 34.94 $\pm$ 8.27 kg). Changes in BMI were not significantly different between groups, although the combination therapy group had a lower increase in BMI, particularly in mid-pubertal patients ($P = 0.024$).
Conclusions
Adding GH to GnRH analog therapy improves final height outcomes in girls with CPP without significantly affecting BMI. GH supplementation may also reduce weight gain commonly observed with GnRH analog therapy. These findings emphasize the importance of a personalized approach based on pubertal stage and metabolic risk. Further studies are needed to confirm long-term outcomes and refine treatment strategies.

ZTTK syndrome with growth hormone deficiency: a case report and literature review

Ha young Jo[1] & Yoon Jae Cho[1]
[1]Pusan National University Hospital, Department of Orthopaedic Surgery, Busan, South Korea

Growth hormone deficiency (GHD) is a disorder of growth hormone secretion from the pituitary gland. Its clinical presentation can include neonatal hypoglycemia, prolonged jaundice, and midfacial defects. However, in children, it sometimes presents only as short stature and/or growth deceleration. GHD is diagnosed when children with short stature (<2 standard deviation score [SDS] relative to the general population) show delayed bone age and peak growth hormone levels of less than 10 ng/ml in at least two growth hormone stimulation tests. For patients who show growth faltering and/or a suboptimal response even when treated with recombinant human growth hormone, additional phenotypes, such as severe short stature and body disproportion, should be assessed, and additional diagnoses should be considered. A 5-year-old girl visited the Department of Pediatrics because of short stature and low weight. She had previously undergone karyotyping and single nucleotide polymorphism (SNP) array testing because of developmental delay, intellectual disability, short stature, and distinctive facial dysmorphisms, including frontal bossing, deep-set eyes, low-set ears, depressed nasal bridge, and short philtrum after birth. The results at the time showed no abnormal finding, but GHD was diagnosed in growth hormone stimulation tests. She was being treated with a high dose of growth hormone (50 μg/kg/day) for GHD in children born SGA, and showed a poor rate of growth even after 5 years of treatment, with a height SDS of -3.98 (formerly -4.05). However, following next-generation sequencing (NGS)-based whole exome sequencing (WES), the patient was diagnosed with Zhu-Tokita-Takenouchi-Kim (ZTTK) syndrome (OMIM: 617140), due to a heterozygous mutation in SON. She is currently continuing growth hormone treatment, as well as receiving pediatric rehabilitation and orthopedic care. Recently, following advances in molecular genetic techniques, genetic causes for many endocrinological diseases have been discovered; hence, genetic testing is commonly used in the diagnosis and genetic counseling of endocrinological diseases. Guidelines for the genetic testing of children with short-stature have also been established. Generally, this disease is unrelated to GHD; however, in 2020, a case of ZTTK syndrome accompanied by GHD with a unique presentation was reported. We believe that this case may be useful references for expanding the genotype-phenotype map. Here, we report the case of ZTTK syndrome with GHD diagnosed by WES in a patient with GHD who did not respond well to GH treatment.

Whole exome sequencing uncovers the genetic diagnoses and new candidate genes for growth disorders in a cohort from the brazilian amazon

Andréa Novaes[1], Nathalia de Andrade[2], Vivian Avelino[3], Marcella Ayonan[4], Randerson Jose Sousa[5], Daniel Nascimento[6], Yuka Nishikawa[3], Maria Izabel Gonçalves[2], Alexsandra Malaquias[7,8] & Alexander Jorge[2]
[1]Universidade do Estado do Para (UEPA), Departamento de Saúde Integrada, Santarem, Brazil; [2]Faculdade de Medicina da Universidade de Sao Paulo, Disciplina de Endocrinologia, Unidade de Endocrinologia Genética, Laboratório de Endocrinologia Celular e Molecular LIM 25, Sao Paulo, Brazil; [3]Universidade do Estado do Pará (UEPA), Departamento de Saúde Integrada, Santarem, Brazil; [4]Universidade Federal do Oeste do Pará, Ciências da Saúde, Santarem, Brazil; [5]Universidade do Estado do Para, Departamento de Saúde Integrada, Santarem, Brazil; [6]Universidade do Estado do Pará, Departamento de Saúde Integrada, Santarem, Brazil; [7]Irmandade da Santa Casa de Misericordia de Sao Paulo, Pediatrics, Sao Paulo, Brazil; [8]Irmandade da Santa Casa de Misericordia de Sao Paulo, Unidade de Endocrinologia Pediatrica, Sao Paulo, Brazil

Introduction
Growth disorders are one of the main challenges in pediatric endocrinology, significantly affecting the quality of life of children and adolescents. The use of next-generation sequencing technologies, such as whole-exome, has revolutionized the investigation of genetic disorders.
Objective
This study aimed to identify new genetic-molecular alterations in patients with growth disorders and characterize the phenotype of rare genetic causes of monogenic growth disorders in the Amazon region.
Methods
Twenty-two patients (15 males; 7 females) clinically diagnosed with idiopathic short stature with or without syndromic features, treated in Santarem, Brazil were selected for exome sequencing.
Results
The average age of the participants at their first presentation to the clinic was 6.7 $\pm$3.7 years. Bone age minus chronological age showed a mean delay of -1.0 $\pm$ 1.7 years in relation to chronological age. The participants Z-score for height was -3.0 $\pm$1.0. Three patients were born small for gestational age. Of the seven syndromic children, one was found with heterozygous deletion of Xp22.33 confirmed by MLPA and another child had homozygous deletion involving the *CLCNKB* gene which confirmed Bartter syndrome type 3. Two other children harbored heterozygous likely pathogenic and VUS variants in *LZTR. LZTR* germline mutations have been known to cause dominant and recessive forms of Noonan syndrome. Another child harbored heterozygous pathogenic variant in *CDK13,* and this is clinically associated with congenital heart defects, dysmorphic facial features, and intellectual developmental disorder. One syndromic child had a negative result in exome sequencing. There were fifteen non-syndromic cases. Ten of the non-syndromic children had negative results in exome sequencing however two of these children had secondary findings: Lynch syndrome and malignant hyperthermia. One child harbored heterozygous deletion of Xp22.33 which confirmed SHOX deficiency disorder. The other four children harbored candidate genes including *IBR4*, *IHH*, *RARA* and *MAU* genes.

Conclusions
This research enabled patients from the Brazilian Amazon to benefit from the use of exome sequencing in the investigation of idiopathic short stature, allowing the identification of new genes that may be involved in growth disorders and the detection of monogenetic diseases, such as SHOX deficiency disorder, Bartter syndrome type 3 and secondary findings having significant implications in the clinical segment, therapeutic decision and genetic counseling. This made it possible to rationally and viable apply genomic medicine in clinical and research practice.

Rare TXNRD2-related familial glucocorticoid deficiency in a chinese patient: a case report

xiaoyan wang[1,2]
[1]children's hospital of soochow university, suzhou, China; [2]Children's Hospital of Soochow University, Suzhou, China

Familial glucocorticoid deficiency (FGD) is a rare autosomal recessive disorder that is primarily characterized by isolated glucocorticoid deficiency. Mutations of *MC2R*, *MRAP*, *STAR*, *NNT*, and *TXNRD2* have been shown to cause FGD. There have been 2 cases reported of mutations in the *TXNRD2* gene causing familial glucocorticoid deficiency-5 (FGD5) in the world. We report a patient who had clinical features consistent with FGD5, increasing the total number of reported cases. This patient is the third case in the world. The details of this case confirm the importance of the *TXNRD2* gene in adrenal cortex redox homeostasis and provide further insights into the nature of FGD5. Further experiments demonstrate that the newly identified variant causes a decrease of TXNRD2 protein levels when expressed in a heterologous expression system. The *TXNRD2* compound heterozygote variant can cause FGD5. The *TXNRD2* compound heterozygote variant of FGD5 may be associated with abnormal findings on electrocardiography. Our case expands on this genetic variation and provides new evidence for the clinical diagnosis of FGD5.

GH therapy and its short-term effectiveness in hong kong (the growth study)

Antony Fu[1], Malika Alimussina[2], Jillian Bryce[2], Minglu Chen[2], Sanhita Koley[2], Jessica Anderson[2], Ting Ting Chen[3], Kate Chan[3], Suki Suk Yan Chan[4], Kent Ho-chung Yau[5], Jacky Chung[6], Sammy Wong[7], Eunice Wong[8], Winnie Yuen[9], Suet Ching Chen[2] & Faisal Ahmed[2]
[1]Princess Margaret Hospital, Hong Kong, The Chinese University of Hong Kong, Paediatric and Adolescent Medicine, Hong Kong, Hong Kong; [2]University of Glasgow, Glasgow, United Kingdom; [3]Chinese University of Hong Kong, Hong Kong, Hong Kong; [4]Prince of Wales Hospital, Hong Kong, Hong Kong; [5]Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, Hong Kong; [6]Caritas Medical Centre, Hong Kong, Hong Kong; [7]Alice Ho Miu Ling Nethersole Hospital, Hong Kong, Hong Kong; [8]Tuen Mun Hospital, Hong Kong, Hong Kong; [9]Kwong Wah Hospital, Hong Kong, Hong Kong

Background
To understand the use of recombinant human growth hormone (GH) therapy (rhGH) in Hong Kong, six paediatric centres in Hong Kong have used the GloBE-Reg platform to systematically collect data on rhGH in children and adolescents.
Methods
A descriptive and comparative analysis of retrospective data of local patients treated with rhGH on GloBE-Reg (https://globe-reg.net/). Anthropometric measurements were converted into standard deviation scores (SDS) using local reference data. Baseline height SDS (HtSDS) and first-year response to rhGH, including delta HtSDS, were calculated.
Results
Of the 294 cases in the registry, baseline and first-year data were available for 261(89%) (M:F, 126:135). All cases received daily rhGH. Among these 261, 107 (41%) had GH deficiency (GHD), with rhGH initiated at a median age of 10.9yrs (10^{th}, 90^{th} centiles, 5.9, 14.3). The median HtSDS increased from -3.2 (-4.2, 1.9) at baseline to -2.7 (-3.8, 1.4) after one year, with a median delta HtSDS of 0.4(-0.1, 1.1). A total of 47 (18%) cases received rhGH for idiopathic short stature, with therapy initiated at a median age of 11.0yrs (5.6, 13.9). Over the first year, the median HtSDS increased from -2.9 (-4.1, -2) to -2.4 (-3.5, -1.8), with a median delta HtSDS of 0.5 (0.2, 1.1). Among the 46 (18%) patients with Turner syndrome, rhGH was initiated at a median age of 10.6yrs (4.4, 14.7). The median baseline HtSDS was -3.5 (-4.5, -2.6), increasing to -3.0 (-4.2, -2) after one year, with a median delta HtSDS of 0.5 (0.03, 0.9). In the 15 (6%) patients with Prader-Willi syndrome, rhGH commenced at a median age of 3.8yrs (1.1, 13.1). The median baseline HtSDS was -1.8 (-3.5, -0.4), improving to -1.4 (-2.4, 0.3) after one year, with a median deltaHtSDS of 0.8 (-0.2, 1.3). In the 19 (7%) cases classified as "Other Disorders" who did not have a clear rhGH indication, rhGH was initiated at a median age of 9.6yrs (4.4, 10.7). The median baseline HtSDS reduced from -0.3 (-3.7, 2.5) to -0.7 (-3.1, 2.2) over the first year, with a median delta HtSDS of -0.3 (-0.6, 0.8). Compared to the GHD group, the median first-year delta HtSDS was significantly lower in the "Other Disorders" group ($P < 0.0001$).
Conclusion
This is the first study to characterize the local treatment landscape of rhGH in children and adolescents. The observed heterogeneity in treatment response in Hong Kong requires further analysis so that clinical effectiveness can be optimised.

Identification of a novel IGF1R mutation in a family with short stature: a case report

Hwalrim Jeong[1] & Hye Jin Lee[2]
[1]Soonchunhyang University, Cheonan, South Korea; [2]Hallym University, Pediatrics, Seoul, South Korea

Background
Insulin-like growth factor 1 receptor (IGF1R) mutations are rare genetic variants associated with growth failure due to impaired IGF1 signaling. We report a family with a novel likely pathogenic IGF1R mutation presenting with short stature, elevated IGF1 levels, and suboptimal growth response to growth hormone (GH) therapy.
Case Presentation
A 4-year-old boy born at 37 + 1 weeks by cesarean section with a birth weight of 2210 g (SGA) presented with short stature below the 3rd percentile. GH stimulation testing revealed a peak GH level of 13.7 ng/ml, indicating normal GH secretion. Initial IGF1 levels were significantly elevated at 202 ng/ml (reference range: 26.8–134 ng/ml for 4-year-old boys). Genetic analysis using a short stature NGS panel identified a heterozygous likely pathogenic IGF1R mutation (c.16G > A, p.Glu56Lys). Despite starting GH therapy (0.23 mg/kg/week), the patient showed a poor growth velocity, and his height percentile remained below the 10th percentile. The proband's 8-year-old sister, who had been treated for idiopathic short stature (ISS) with GH therapy since the age of 5, exhibited persistently elevated IGF1 levels (576 ng/ml) without achieving height above the 10th percentile. Genetic testing confirmed the same IGF1R mutation. Their mother, with a height of 148 cm, was also found to carry the heterozygous mutation.
Conclusion
This family highlights the clinical characteristics of a novel IGF1R mutation, including short stature, elevated IGF1 levels, and suboptimal response to GH therapy. These findings underscore the importance of genetic evaluation in patients with short stature and poor response to GH treatment. Further functional studies of the c.16G > A, p.Glu56Lys variant are needed to understand its impact on IGF1 signaling and growth

The impact of puberty on IGF-1: factors influencing growth and development

Nada Alaaraj[1], Ashraf Soliman[1], Ahmed Elawwa[1], Shayma Ahmed[1], Noor Hamed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Insulin-like growth factor 1 (IGF-1) plays a pivotal role in pubertal growth and development. Its levels peak during puberty, driven by growth hormone (GH) secretion, and are influenced by factors such as sexual dimorphism, nutritional

Table 1. Key Factors Influencing IGF-1 Levels During Puberty

Factor Addressed	Main Findings
Peak Levels During Mid-Puberty	GH and IGF-1 peak during puberty, driving skeletal growth and bone density.
Sexual Dimorphism	IGF-1 levels differ by sex, influenced by androgen and estrogen modulation.
Interdependence with Nutritional Status	Nutritional status strongly impacts IGF-1 levels; malnutrition blunts growth effects.
Variability in Onset and Duration	Delayed or precocious puberty alters IGF-1 timing, affecting growth trajectories.

status, and the timing of puberty onset. These interactions highlight IGF-1's critical role in skeletal growth, sexual maturation, and overall development.
Objective
To explore the effects of puberty on IGF-1 levels and identify the factors—peak levels, sexual dimorphism, nutritional status, and timing variability—that influence its patterns during this
Methods
A comprehensive review of 10 studies was conducted, spanning various subjects, including adolescents, animal models, and *in vitro* research. The studies address IGF-1 dynamics during mid-puberty, sexual dimorphism, the influence of nutrition, and the variability in IGF-1 timing due to delayed or precocious puberty.
Results: Table
1. Peak Levels During Mid-Puberty: GH and IGF-1 levels reach their highest during mid-puberty, essential for skeletal growth and bone density (Locatelli & Bianchi, 2014; Dixit *et al*., 2020).
2. Sexual Dimorphism: IGF-1 levels differ by sex, influenced by androgen and estrogen modulation, with higher levels noted during central precocious puberty in girls (Juul & Skakkebæk, 2019; Sørensen *et al*., 2012; Venken *et al*., 2006).
3. Interdependence with Nutritional Status: Malnutrition and chronic illness blunt IGF-1 levels, limiting growth, while well-nourished adolescents maintain higher IGF-1 levels (Mohan *et al*., 2003; Acerini *et al*., 2001; Turchyna *et al*., 2022).
4. Variability in Onset and Duration: Delayed or precocious puberty alters the timing and variability of IGF-1 levels, impacting growth trajectories (Dees *et al*., 2021).
Discussion
Puberty-induced IGF-1 changes are driven by GH secretion and influenced by multiple factors. Sexual dimorphism highlights hormonal modulation, while nutritional status underpins the IGF-1 response. Variability in timing emphasizes the dynamic nature of IGF-1, reflecting broader growth and developmental processes.
Conclusion
IGF-1 levels during puberty and the interplay of peak levels, sex differences, nutritional factors, and timing variability underscores its multifaceted role, necessitating a tailored approach to understanding IGF-1 dynamics.

Safety profile of large IGF-1 fluctuations: long-acting growth hormone therapy vs. daily growth hormone therapy

Ashraf Soliman[1], Ahmed Elawwa[1], Nada Alaaraj[1], Noor Hamed[1], Shayma Ahmed[1], Ahmed Khalil[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Long-acting growth hormone (GH) therapy offers improved adherence and convenience compared to daily GH therapy, but it is associated with periodic IGF-1 fluctuations due to its extended release profile. The clinical safety of these fluctuations and their potential impact on adverse events remain important considerations in choosing therapy for GH deficiency (GHD).
Objective
To evaluate the safety profile of long-acting GH therapy compared to daily GH therapy, focusing on the implications of IGF-1 fluctuations and potential adverse outcomes.
Material and Methods
A comprehensive review of studies was conducted comparing safety profiles between long-acting GH therapies (e.g., somapacitan, TransCon GH) and daily GH therapies (e.g., Genotropin). Data were extracted on IGF-1 fluctuations, IGF-1 SDS excursions, and adverse events. The results are summarized in a comparison table.
Results
Key Findings:
1. Long-Acting GH Therapy:
• **Fluctuations:** Large IGF-1 peaks were observed post-injection, typically on days 3–4, with troughs approaching baseline by day 7.
• **Safety:** Minimal adverse events were reported despite IGF-1 SDS excursions > 2.0 in some patients, particularly at higher doses.
• **Specific Studies:**
• Kildemoes *et al*. (2023): Weekly somapacitan showed transient IGF-1 SDS excursions >2.0 but was well-tolerated.
• Chatelain *et al*. (2017): IGF-1 SDS >2.0 occurred in 4/14 patients at the highest dose of TransCon GH, with no clinical adverse events or dose modifications.
• **Adverse Events:** Rare occurrences of injection-site reactions and mild transient hyperglycemia.
2. **Daily GH Therapy:**
• **Fluctuations:** Daily administration resulted in smaller, more consistent IGF-1 fluctuations, typically maintaining IGF-1 SDS <1.0.
• **Safety:** Well-tolerated with no IGF-1 SDS excursions above therapeutic thresholds.
• **Specific Studies:** Garner *et al*. (2023): No significant adverse events were observed, with stable IGF-1 levels within the therapeutic range.
Discussion
The larger IGF-1 fluctuations observed with long-acting GH therapies are generally transient and dose-dependent, with no significant safety concerns reported in short-term studies. Daily GH therapy exhibits a more stable IGF-1 profile, minimizing the risk of IGF-1 excursions but requiring frequent dosing. Long-term monitoring is necessary to assess the clinical implications of sustained IGF-1 peaks with long-acting therapies.
Conclusion
Long-acting GH therapy is a safe and effective alternative to daily GH therapy, despite larger IGF-1 fluctuations. Careful dose titration and regular monitoring are essential to minimize transient IGF-1 SDS excursions and maintain a favorable safety profile.

Diagnostic utility of IGF-1 levels in growth and puberty-related disorders: a comprehensive review

Fawzia Alyafei[1], Abir Ali[1], Shayma Ahmed[1], Noor Hamed[1], Nada Alaaraj[1] & Ashraf Soliman[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Insulin-like growth factor 1 (IGF-1) serves as a key biomarker in assessing growth and puberty-related conditions. Variations in IGF-1 levels reflect underlying pathophysiological changes, helping to differentiate between normal growth and growth-related disorders such as Growth Hormone Deficiency (GHD), Turner Syndrome, and Constitutional Delay of Puberty (CDP). However, standardizing IGF-1 cut-offs across different conditions remains challenging.
Objective of the Review
This review consolidates data from multiple studies to summarize the diagnostic IGF-1 cut-offs across various growth and puberty-related conditions and highlights its utility and limitations as a diagnostic tool.
Material and Methods
A comprehensive analysis was performed by synthesizing findings from studies published in peer-reviewed journals. Data on IGF-1 levels in conditions such as CDP, Small for Gestational Age (SGA), Chronic Malnutrition, GHD, Turner Syndrome, and rare genetic mutations were extracted and compared.
Results
1. **IGF-1 cut-off for normal growth**: Typically ranged between 150-200 ng/ml across conditions.
2. **GHD**: Consistently indicated by IGF-1 levels < 100 ng/ml in multiple studies.
3. **SGA**: IGF-1 levels < 100 ng/ml or 110 ng/ml in various studies supported its role as a disease marker.
4. **Turner Syndrome**: IGF-1 < 120 ng/ml was associated with disease states, with larger studies reinforcing this threshold.
5. **Chronic Malnutrition and Thalassemia Major**: IGF-1 levels < 90 ng/ml and < 70 ng/ml, respectively, indicated growth disturbances.
6. **Rare conditions**: IGF1R mutations presented variable or fluctuating IGF-1 levels, reflecting unique pathophysiology.
Discussion
IGF-1 levels provide a reliable diagnostic indicator for many growth-related disorders, with thresholds helping clinicians differentiate between normal and pathological growth states. Larger studies, particularly on conditions like Turner Syndrome, provide robust diagnostic thresholds, while rare cases emphasize the variability due to genetic and environmental factors.
Conclusions
IGF-1 is a critical diagnostic marker for growth and puberty-related conditions. While general thresholds like IGF-1 < 100 ng/ml for GHD and SGA are well-

Table: IGF-1 cut Levels by Condition

Condition	IGF-1 Cut-Off (Normal)	IGF-1 Cut-Off (Abnormal)
(CDP)	> 150 ng/mL	< 150 ng/mL
(SGA)	> 200 ng/mL	< 100â£″110 ng/mL
Chronic Malnutrition	> 180 ng/mL	< 90 ng/mL
Turner Syndrome	> 170â£″200 ng/mL	< 120 ng/mL
(ISS)	> 160 ng/mL	Normal or near normal
(GHD)	> 200 ng/mL	< 90- 100 ng/mL
Noonan Syndrome	> 150 ng/mL	< 80 ng/mL
Thalassemia Major	> 150 ng/mL	< 70 ng/mL
IGF1R Deletion	Fluctuating	Fluctuating

supported, variability in levels across different conditions and populations necessitates cautious interpretation alongside clinical context.

JOINT1457

Are children with atopic eczema at higher risk of poor linear growth? - A systematic review of the literature

Kah Yin Loke[1,2] & Nicholas Beng Hui Ng[1,2]
[1]Khoo Teck Puat - National University Children's Medical Institute, Department of Paediatrics, National University Health Systems, Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]Department of Paediatric, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background
The evidence on the association between atopic dermatitis (AD) and linear growth in children in current literature is inconsistent. Some studies have suggested that the presence of AD may negatively impact height, while other studies have not reported similar associations. This systematic review aims to evaluate the association between AD and linear growth in children, and determine factors that may be potentially associated with compromised linear growth in children with AD.
Methods
A PRISMA-compliant systematic review was conducted. Databases included in the review were PubMed, Embase, Scopus and Cochrane. The search timeline was from database inception to June 2024. Inclusion criteria includes articles that reported a quantitative relationship between AD and linear growth in children (< 18 years old). The quality of included articles was assessed using the Joanna Briggs Institute Critical Appraisal Tools, while quality of evidence in these studies was evaluated using Grading of Recommendations Assessment, Development and Evaluation (GRADE) criteria. A meta-analysis was not performed due to significant clinical and methodological heterogeneity between the studies that met inclusion criteria.
Results
Fourteen studies which comprises 50,146 patients with AD were included. Seven studies reported either a "strong positive" or "positive" association between AD and reduced height standard deviation score (SDS) in children; the remaining 7 studies reported no association between AD and height. Only 3 of the 14 studies had moderate quality of evidence, all of which had reported an association between AD and poorer height SDS; while the remaining 11 studies scored low in quality of evidence. Three studies reported the impact of AD on height to be transient, mimicking constitutional growth delay. In addition, severity of AD, timing of onset of AD, sleep disruption and extent of nutritional restrictions are important risk factors for linear growth impairment in patients with AD. Topical steroid use did not appear to be associated with shorter stature in patients with AD.
Conclusions
The evidence at present reporting on the association between childhood AD and poor linear growth is weak and inconsistent. However, patients with more severe AD, earlier disease onset, poorer sleep quality and higher nutritional restrictions appear more susceptible to linear growth impairment. Therefore, management of patients with AD should not only be focused on treatment and control of the disease, but also on optimizing growth, nutrition, sleep and quality of life.

JOINT2429

Clinical features and genetic analysis of an SGA-born patient with IGF1R heterozygous mutation

Mehmet Ali Oktay[1], Aylin Kılınç Uğurlu[1], Esra Döğer[1], Gülsüm Kayhan[2], Mahmut Orhun Çamurdan[1] & Aysun Bideci[1]
[1]Gazi University Faculty of Medicine Hospital, Department of Pediatric Endocrinology, Ankara, Türkiye; [2]Gazi University Faculty of Medicine Hospital, Department of Medical Genetics, Ankara, Türkiye

Introduction
The *IGF1* and *IGF1R* genes regulate prenatal and postnatal growth processes. Mutations in the *IGF1R* gene can cause intrauterine growth restriction (IUGR), postnatal growth retardation, microcephaly, intellectual disability, neurodevelopmental issues, and brain and cardiac anomalies. Biallelic mutations generally result in more severe phenotypes than heterozygous mutations. *IGF1R* mutations are a significant etiological factor in patients with small gestational age (SGA) and growth retardation. Genetic analysis of these mutations is critical for early diagnosis and treatment strategies.
Case
Report
This report describes a 1-year-4-month-old male patient born SGA (38th week, 1975 g, −3.76 SD) with ongoing growth retardation. The birth length was 45 cm (−2.19 SD), and the calculated mid-parental height was 171.2 cm (−0.81 SD). No consanguinity was identified. Physical examination revealed a height of 72.5 cm (−2.7 SD), body weight of 6.8 kg (−4.09 SD), and head circumference of 43.5 cm (−3.12 SD). Testicular volume was 2/2 ml and penile length were normal for his age. Liver, kidney, and thyroid function tests were normal, and celiac autoantibodies were negative. At the time of the patient's admission, IGF1 levels were measured at 46.1 ng/ml (−1 SD), and IGFBP3 levels at 3008 ng/ml (+1 SD). No abnormalities were observed during blood glucose monitoring. Nutritional support was initiated due to malnutrition, but growth velocity remained insufficient. Genetic analysis identified a heterozygous c.3595G > A p.(Gly1199Arg) variant in the *IGF1R* gene, also detected in the mother. Although growth hormone therapy was recommended, the family declined treatment.
Discussion
Mutations in *IGF1R* lead to phenotypes resembling IGF1 deficiency but require different therapeutic approaches. The IGF1 receptor regulates growth, metabolism, and cell survival via the MAPK/ERK and PI3K → AKT pathways. *IGF1R* defects may mimic Silver-Russell or SHORT syndrome phenotypes, with microcephaly as a distinguishing feature. Walenkamp *et al.* proposed a clinical scoring system for *IGF1R* mutations based on low birth weight, small head circumference, short stature, and elevated IGF1 levels. Recombinant growth hormone (rGH) therapy's efficacy in *IGF1R* mutations remains unclear. Studies report modest height gains (average 1.0 SDS) with rGH but caution against dose escalation due to high IGF1 levels. The genotype-phenotype correlation for *IGF1R* mutations remains unresolved. Heterozygous carriers typically exhibit milder phenotypes than homozygous individuals. This case represents the first Turkish pediatric patient with the *IGF1R* Gly1199Arg variant.

Experience with growth hormone therapy in a rare skeletal dysplasia

Elif Tuğçe Tunca Küçükali[1], Aylin Kılınç Uğurlu[1], Esra Doger[1], Gülsüm Kayhan[2], Mahmut Orhun Çamurdan[1] & Aysun Bideci[1]
[1]Gazi University Faculty of Medicine Hospital, Department of Pediatric Endocrinology, Ankara, Türkiye; [2]Gazi University Faculty of Medicine Hospital, Department of Medical Genetics, Ankara, Türkiye

Introduction
Cartilage oligomeric matrix protein (COMP) is a pentameric extracellular matrix glycoprotein that is critical for collagen formation and extracellular matrix stability. Mutations in the COMP gene lead to impaired extracellular matrix stability, secondary chondrocyte apoptosis, and two rare skeletal dysplasias: pseudoachondroplasia (PSACH) and multiple epiphyseal dysplasia (MED). Here, we present a case of a patient diagnosed with a COMP gene mutation, who was followed in our clinic due to short stature.
Case Report
A 6-year-7-month-old girl was referred to our clinic by the rheumatology department for short stature. Her medical history revealed that she was born at 39+4weeks of gestation and gestation weight was 2660grams, she had always been shorter than her peers, and was under follow-up for Familial Mediterranean Fever(FMF) with no attacks after colchicine treatment. There was no consanguinity between her parents. The mother's height was measured as 150.9cm, and the father's height as 165cm(mid-parental height: 151.4cm). Physical examination showed a body weight of 16.5kg(-1.94SD), height of 106.5cm(-2.5SD), and Tanner stage 1 puberty. Laboratory investigations revealed an IGF-1 level of 152ng/ml (+1SD), IGFBP3 level of 4281ng/ml (0/+1SD), normal thyroid function tests, negative celiac antibodies, and a bone age of 6years

and 9months. Growth hormone stimulation testing demonstrated a peak response of 20.4ng/ml. The patient was monitored for growth velocity, which was found to be 3.7cm/year.Subsequently, somatropin therapy was initiated. Under treatment, growth velocities were observed as 7cm/year in the first year,8.3cm/year in the second year, and 7.6cm/year in the third year, with IGF-1 levels at +1SD. Chromosome analysis showed 46,XX, and a genetic panel for short stature identified a heterozygous c.1767C>A (p.Asn589Lys) variant in the COMP gene, classified as a variant of uncertain significance (VUS) close to pathogenicity. As the variant was evaluated as potentially pathogenic and the patient's final bone age was consistent with 14years, somatropin therapy was discontinued. At her last follow-up, the patient was 12years old with a bone age of 14years, a body weight of 35.9kg (-1.28SD), height of 138.1cm (-2.35SD), and Tanner stage 4puberty. The patient's growth velocity declined due to the discontinuation of treatment and her untreated growth velocity was 2.4cm/year.

Discussion/Conclusion

Although COMP gene mutations typically lead to two rare skeletal dysplasias, they can present as idiopathic short stature without overt skeletal dysplasia findings. COMP, which plays a role in extracellular matrix stabilization, has been shown to correlate with serum levels of chondrocytes, growth hormone, and IGF-1. Therefore, growth hormone therapy may contribute to final height outcomes in short stature cases with COMP gene mutations.

Experience after 30 years of acromegaly management at the hospital clínico universitario de valladolid

Esther Delgado García[1,2], Paloma Perez[1,2], Ana Ortolá[1,2], Beatriz Torres[1,2], Gonzalo Diez[1,2], Emilia Gomez[1,2], Rebeca Jimenez[1,2], Juan Jose Lopez[1,2] & Daniel De Luis Roman[1,2]

[1]Servicio de Endocrinologia y Nutricion, Hospital Clinico Universitario de Valladolid (España), Valladolid, Spain; [2]Instituto investigacion de Endocrinologia y Nutricion. Ienva., Facultad de Medicina de Valladolid, Valladolid, Spain

Introduction

Acromegaly is a condition primarily treated with surgery.

Objective

To describe the diagnostic and therapeutic evolution of acromegaly patients over the past 30 years in a tertiary hospital.

Material and Methods

A retrospective observational study of patients diagnosed with acromegaly between 1993 and 2023 at the Hospital Clínico Universitario de Valladolid, Spain. Clinical, radiological, and laboratory characteristics were collected at diagnosis, in the immediate postoperative period, and after one year, as well as histopathological findings and treatment details.

Results

A total of 34 patients were analyzed, 55.9% of whom were women, with a mean age of 59.7 (14.2) years. The main clinical presentations were **hormonal excess (62.5%)**, **compressive symptoms (20.8%)**, or both (16.7%). One case of pituitary apoplexy was recorded, and two patients (3%) were diagnosed with MEN-1. The main associated comorbidities are shown in Figure 1. MRI was the first radiological test in **90.9%** of cases, identifying **macroadenomas in 80.8%**. Tumors extended **suprasellarly in 22.2%**, **laterally in 7.4%**, and **demonstrated invasive criteria in 7.4%** (more than two locations). Surgery was performed in **30 patients**, with the **endoscopic approach (63.6%)** being the most common, followed by **direct endonasal (27.3%)**. The mean tumor volume reduction was **88.1%**. Hormonally, a **significant reduction in IGF-1 levels** (563.4 (297.6) vs. 263.2 (206.9); $P < 0.01$) and a **trend toward GH reduction** (20.6 (25.3) vs. 5.3 (7.6); $P = 0.057$) were observed one year post-surgery. Immunohistochemical analysis was performed in **38.2%** of cases, revealing **42.9% prolactin co-secretion**, and **two cases of GH, PRL, and ACTH co-secretion**. Disease persistence was observed in **63.3%** of patients, and **radiotherapy was administered to 11 patients**. Pharmacological treatment was initiated in **56.7%** of patients at diagnosis, **16 patients in the immediate postoperative period**, and **19 in the late postoperative period**. One year post-surgery, **29.4% were receiving Lanreotide**, **8.8% Octreotide**, **one patient Pegvisomant**, and **one Pasireotide**. **Three patients** received concomitant dopamine agonists. **Corticosteroid replacement therapy was required in 51.7% of patients in the early postoperative period** and **23.3% in the late postoperative period**.

Conclusion

Surgery remains the primary treatment for acromegaly, achieving high tumor volume reduction and a significant decrease in IGF-1 levels, although **disease persistence remains frequent (63.3%)**. More than half of the patients required **postoperative pharmacological treatment**, and some underwent **radiotherapy**. These findings highlight the need for a **multidisciplinary approach to optimize disease control**.

Cranio-lenticulo-sutural dysplasia (CLSD) as a rare cause of syndromic short stature: a case report of a complex clinical presentation

Davide De Brasi[1], Livia Barba[1], Elisabetta Scarano[1], Roberto Novizio[1], domenico serino[1], Vincenzo Novizio[1], Chiara Vitiello[2] & Francesco Scavuzzo[1]

[1]Antonio Cardarelli Hospital, Naples, Italy, Endocrinology Department, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione, Naples, Italy

Introduction

Cranio-lenticulo-sutural dysplasia (CLSD), also known as Boyadjiev-Jabs syndrome (ORPHACODE 50814), is a rare disorder characterized by large, late-closing fontanelles, hypertelorism, early-onset cataracts, and skeletal dysplasia. It is primarily inherited in an autosomal recessive manner, though rare autosomal dominant cases have been reported.

Case Report

An 11-year-old male was referred for short stature evaluation. His height was 130.1 cm (<3rd percentile, –2.66 SD), with a growth velocity of 3.5 cm/year (9th percentile). He had a proportionate body structure, normal head circumference (51.5 cm, 10th percentile), and delayed bone age (by ~3 years). Pubertal stage was Tanner P1G1. Born SGA (2480 g, <10th percentile) at 39 weeks via emergency cesarean section, he had cryptorchidism with a right inguinal hernia (surgically corrected at 10 months) and congenital heart defects (ASD and VSD), which closed spontaneously by age four. His cranial fontanelles closed at nine years. Facial dysmorphisms included a prominent forehead, hypertelorism, and low-set ears, with skin hyperpigmentation and a frontal hemangioma. He exhibited mild psychomotor developmental delay (PMDD) with muscular hypertonia, dystonic movements, and facial tics. Due to PMDD, brain and spinal MRI was conducted, revealing an empty sella and a small osteoangioma at D3. However, FRAXA analysis, array-CGH, plasma and urinary amino acid profiles were all within normal limits. Regarding his proportionate short stature associated with empty sella, routine blood tests, celiac serology, pituitary hormone profile, and sweat test were performed, all yielding normal results except for a low IGF-1 level for age. The patient subsequently underwent an arginine stimulation test, which demonstrated a normal GH peak (9.7 ng/ml). Whole exome sequencing ultimately identified a de novo heterozygous missense variant, c.2146C>T (p. Arg716Cys), in the **SEC23A** gene (14q13-q21), classified as likely pathogenic (Class 4). Given his syndromic short stature, SGA birth without catch-up growth, he recently started recombinant human GH (rhGH) at 30 mg/kg/day, with treatment ongoing.

Conclusions

This case presents notable features, including the autosomal dominant inheritance of cranio-lenticulo-sutural dysplasia and the ongoing treatment with rhGH, which has not been previously reported in the literature for this rare disorder. This highlights the importance of comprehensive genetic investigations in patients with suspected syndromic short stature.

Differences in treatment efficacy between idiopathic short stature and other conditions with advanced bone age

Ashraf Soliman[1], Fawzia Alyafei[1], Ahmed Elawwa[1], Noora AlHumaidi[1], Nada Alaaraj[1], Noor Hamed[1], Shayma Ahmed[1] & Ahmed Khalil[1]

[1]Hamad Medical Corporation, Doha, Qatar

Background

Children with advanced bone age (ABA) and short stature present a therapeutic challenge. Idiopathic short stature (ISS) with ABA often involves delayed height gain despite treatment, contrasting with other conditions like congenital adrenal hyperplasia (CAH), obesity-related short stature, precocious puberty, and small for gestational age (SGA), which may show better therapeutic outcomes. The purpose of this review is to compare the efficacy of growth hormone (GH), GnRH analogs (GnRHa), and aromatase inhibitors (AIs) in ISS vs other ABA conditions.

Objectives
To compare therapeutic outcomes in ISS with ABA vs other conditions with ABA, identifying key differences in response to treatment combinations involving GH, GnRHa, and AIs.
Methods
This structured review analyzed 25 studies published between 1994 and 2024, focusing on treatments for ISS and other ABA conditions. Data were extracted regarding patient characteristics, treatment modalities, and main outcomes, and stratified into ISS and specific conditions like CAH, obesity-related short stature, precocious puberty, and SGA. Outcome measures included height standard deviation scores (SDS), predicted adult height (PAH), and bone age progression.
Results
In ISS, combination therapies of GH and GnRHa, or GH and AIs, yielded modest improvements in PAH (5–10 cm), with greater benefits observed in early interventions. However, ABA progression often resumes after treatment discontinuation. Conditions like CAH and precocious puberty responded more robustly to GH, GnRHa, and AI combinations, achieving PAH improvements exceeding 15 cm in certain cases, particularly in prepubertal patients. GH monotherapy showed limited height SDS improvement in obesity-related short stature while adding GnRHa or AIs significantly delayed ABA progression and enhanced final height. SGA cases demonstrated consistent improvements in height SDS with GH and GH+AIs, especially when initiated early, with less adverse impact on ABA. Across conditions, therapy in ISS was less effective at sustaining height gains and controlling ABA compared to CAH, precocious puberty, and obesity-related short stature.
Discussion
The comparative analysis reveals that ISS with ABA has a limited response to GH-based therapies relative to other ABA conditions, underscoring the need for early intervention and tailored approaches. The significant height gains in CAH and precocious puberty highlight the potential of combined therapies in ABA management.
Conclusion
ISS with ABA responds less robustly to therapy compared to other ABA conditions. Combined GH, GnRHa, and AI therapies are more effective in controlling ABA progression and improving height outcomes in CAH, precocious puberty, and SGA, suggesting condition-specific treatment strategies are critical for optimal growth outcomes.

INSIGHTS-GHT: first evaluation of paediatric patients with long-acting growth hormone therapy (LAGH) from the german registry

Joachim Woelfle[1], Christof Land[2], Desiree Dunstheimer[3], Timo Deutschbein[4], Erwin Lankes[5], Ilonka Kreitschmann-Andermahr[6], Christian J. Strasburger[7], David Pittrow[8], Christine Pausch[8] & Dirk Schnabel[5]
[1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, Erlangen, Germany; [2]Zentrum für Kinder- und Jugendendokrinologie, Endokrinologie, Gauting, Bayern, Deutschland, Gauting, Germany; [3]Universitätsklinikum, Klinik für Kinder- und Jugendmedizin, Augsburg, Bayern, Deutschland, Augsburg, Germany; [4]Medicover Oldenburg MVZ, Oldenburg, Germany, Oldenburg, Germany; [5]Charité, Universitätsmedizin, Pädiatrische Endokrinologie/SPZ für chronisch kranke Kinder, Berlin, Berlin, Deutschland, Berlin, Germany; [6]Universitätsklinikum, Klinik für Neurochirurgie und Wirbelsäulenchirurgie, Essen, Nordrhein-Westfalen, Deutschland, Essen, Germany; [7]Charité - Universitätsmedizin Berlin, Klinik für Endokrinologie und Stoffwechselmedizin, Berlin, Berlin, Deutschland, Berlin, Germany; [8]GWT-TUD, Innovationszentrum Real-World Evidence, Dresden, Sachsen, Deutschland, Dresden, Germany

Introduction
INSIGHTS-GHT is the world's first cross-product registry study on growth hormone (GH) therapy. It includes patients of all ages across all approved indications, enabling the documentation of real-world GH treatment patterns from childhood through transition to adulthood in Germany, and the analysis of a wide range of associated relevant scientific questions. In particular, since the end of 2023, patients treated with the newly approved long-acting GH preparations (LAGH) Ngenla© (Somatrogron), Skytrofa© (Lonapegsomatropin) and Sogroya© (Somapacitan) are also documented.
Methods
Since its launch in February 2022, more than 1800 patients from 30 endocrinological institutions in Germany have been included in the INSIGHTS-GHT registry. We report on the first interim evaluation of paediatric patients with growth hormone deficiency (GHD) who are receiving therapy with a LAGH. These patients receive LAGH subcutaneously once weekly. Here we report the findings from a database interim analysis dated 10/Jan/2025.
Results
So far, 62 children and adolescents under the age of 18 with GHD under LAGH from 14 centres have been included. Of these, 76 % are male. 42 cases (70 %) suffer from idiopathic growth hormone deficiency, 18 cases (30 %) have organic growth hormone deficiency. The age at the start of LAGH therapy was 9.2 (3.7) years. The majority of patients (81%) were prepubertal at the start of LAGH therapy. 34 patients (57%) had previously received therapy with daily GH for an average of 4.3 (2.9) years ('switch patients'). The body height at the start of LAGH therapy was -1.9 (1.2) SDS, BMI was -0.4 (1.2) SDS. The starting dose of the long-acting products was below the manufacturer's recommendation in 82 % of cases, with a median of 92 % of the recommended dose.
Conclusion
The INSIGHTS-GHT registry provides an excellent research platform to investigate various aspects of somatropin therapy, including data on the use of the preparations and the long-term effects in terms of safety, efficacy and quality of life. Initial baseline data on paediatric patients on long-acting GH therapy provide indications of its acceptance, indicate initial dosing of LAGH slightly below doses recommended by the manufacturers and will enhance our understanding of clinical practice.

JOINT2854

Clinical and biochemical variation in a consanguineous family with heterozygous MAP2K2 variant and hetero/homozygous TSH receptor variant

Matthias Börschel-Thomsen[1] & Gunter Simic-Schleicher[1]
[1]Klinikum Bremen-Nord, Bremen, Germany

Introduction
MAP2K2 defects cause a cardio-facio-cutaneous syndrome (CFC) with characteristic features with high penetrance. The TSH receptor variations may cause hypo- or hyperthyroid state. Here we describe the clinical and biochemical variations of a consanguineous family where a MAP2K2 mutation (CFC4) and a TSHR mutation are encountered. Focus is given to the large clinical variation in this family and possible associations with the gene variations.
Methods and Results
The parents are 1st grade cousins with 9 children out of which 6 were examined. No typical CFC features and no heart disease were encountered apart from short stature in the mother (151,5 cm) and one of the daughters (149,2 cm). Molecular analysis of this woman showed a mutation in MAP2K2 c.464G>T; Gly135Val close to the critical position 134. It was initially judged as relevant but later as VUS. Also, a TSHR mutation was found (c.202C>T; Pro68 Ser) which was judged as VUS. Nobody had a mental or a somatic developmental delay apart from a boy with GH deficiency and delay of puberty. Height was reduced in 2/6 (< = 1 perc) but normal in 3/6 (24 – 58 perc). One patient has a GH deficiency (before GH 7 perc., near final height 20 perc). Central hypothyroidism was found in 3/4 examined patients, in all of them TSHR variation - homozygous (2/2) or heterozygous (1/1). 2/2 examined had a subtle hypoadrenalism (1 homo-, 1 heterozygous for TSHR).
Discussion
There are no association with this MAP2K2 variant and height. The preponderance of neuroendocrine dysfunctions as central hypothyroidism is present. Hypothyroidism is also linked to the TSHR variant but primary hypothyroidism is expected rendering this link irrelevant. The lack of clear clinical associations to the MAP2K2 variant supports the view as allelic variant. Due to the subtle neuroendocrine dysfunctions a mild pathogenic role cannot completely ruled out.

Prader-willi syndrome: a journey of resilience againt hyperphagia and developmental challenges

Ftouh Wiam[1], Smouni Meriem[1], Temlali Ouafae[1], Aziouez fatima[1] & Benkacem Mariem[1]
[1]University Hospital Center Mohamed VI, Faculty of Medicine and Pharmacy of Tangier, Department of Endocrinology and Diabetology, Tangier, Morocco

Introduction
Prader-Willi syndrome (PWS) is a rare genetic disorder caused by the absence of expression of paternally inherited genes on chromosome 15q11-q13. It is characterized by neonatal hypotonia, developmental delay, hyperphagia, obesity, and endocrine dysfunction.
Case Report
We present the case of a 3-year-old boy born to non-consanguineous parents, with a history of neonatal hypotonia at birth. Clinical examination revealed overweight (26 kg, +3 SD), facial dysmorphism characterized by a narrow forehead, almond-shaped eyes, strabismus, and hypoplastic genitalia with non-palpable testes. Due to ambiguous genitalia, a karyotype was performed, revealing a male chromosomal formula (46,XY). Based on the clinical findings, Prader-Willi syndrome was suspected. A methylation-specific PCR analysis of the SNRPN locus was conducted, confirming the absence of paternal contribution in the 15q11-q13 region, thus establishing the diagnosis of PWS.
Discussion
PWS is characterized by hormonal dysfunction, neonatal hypotonia, hyperphagia, learning difficulties, and behavioral disorders. In cases of severe neonatal hypotonia, an etiological investigation is crucial, particularly when associated with early feeding difficulties. The main complications of this syndrome arise from autonomy challenges and obesity, highlighting the importance of a multidisciplinary management approach to improve quality of life and long-term outcomes.
Keywords
Prader-Willi syndrome, neonatal hypotonia, hyperphagia, genetic disorder, methylation analysis, multidisciplinary management.

Childhood growth hormone deficiency and continuation of therapy in adulthood: case series of patients followed at a tertiary center

Alice Monsanto[1], Margarida Sobral[1], Bárbara Jesus[1], Leonor Rodrigues[2], Tânia Carvalho[1], Gustavo Rodrigues[1], Mariana Lavrador[1], Mara Ventura[1], Luísa Ruas[1] & Leonor Gomes[1]
[1]Unidade Local de Saúde de Coimbra, Coimbra, Portugal; [2]Unidade Local de Saúde de Aveiro, Aveiro, Portugal

Introduction
The transition period in patients undergoing recombinant human growth hormone (rhGH) therapy is a critical developmental phase, beginning at the end of puberty and lasting until early adulthood, typically 6–7 years after reaching final height. Despite slowed linear growth, rhGH remains vital for bone and lipid metabolism, body composition, and quality of life. Re-evaluating the somatotropic axis during this phase is essential, as some individuals diagnosed in childhood may exhibit normal secretion upon retesting. If deficiency persists, therapy continuation ensures complete bone mineralization and mitigates metabolic complications. However, many adolescents discontinue treatment or abandon medical follow-up, highlighting the need for coordinated care between pediatric and adult endocrinologists.
Objective
To characterize adults on rhGH replacement therapy for childhood-onset growth hormone deficiency (GHD) followed at a tertiary endocrinology center.
Methods
A retrospective observational study analyzing clinical records of patients followed until October 2024.
Results
The sample included 18 patients, with a median age of 22.5 (18–48) years, and 66.7% ($n = 12$) were female. The mean age at diagnosis and therapy initiation was 5.4 ($\pm$4.6) years, with a mean final height of 1.61 ($\pm$0.12) meters. The most frequent etiology was congenital structural abnormalities (66.7%), followed by sequelae-related conditions (22.2%), mainly secondary to space-occupying CNS lesions. Multiple hormone deficiencies were present in 88.9% ($n = 16$). Axis re-evaluation occurred at a mean age of 16.9 ($\pm$1.2) years, with a mean IGF-1 level of 97.2 ($\pm$53.9) ng/ml. Dyslipidemia was present in 55.6% ($n = 10$), and 83.3% of those assessed had low bone mineral density (BMD) or were at risk. Fifteen patients continued rhGH therapy without confirmatory testing, while three discontinued due to normal axis function. However, all three resumed therapy following reassessment due to cardiovascular comorbidities, decreased BMD or worsening quality of life.
Conclusion
rhGH replacement is indicated in patients with persistent deficiency during transition, offering long-term benefits. Most patients with persistent GHD had congenital structural abnormalities and multiple hormone deficiencies. Even those who discontinue therapy require active monitoring in adulthood. Continuous management is essential to optimize quality of life and prevent complications associated with chronic GH deficiency.

JOINT3544

Noonan syndrome and growth delay: the hope of optimized growth with growth hormone therapy

Karimi Meryem[1], Ghita Khamel[1], Hajar Azagouagh[1], Ghizlane Sabbar[1], Kawtar Rifai[1], Hinde Iraqi[1] & Mohamed El Hassan Gharbi[1]
[1]CHU Ibn Sina, Rabat, Morocco

Introduction
Noonan syndrome (NS) is a rare autosomal dominant disorder caused by mutations in genes involved in the RAS-MAPK signaling pathway, most commonly the *PTPN11* gene. Patients with this syndrome exhibit characteristic dysmorphic features, cardiac anomalies, and growth delay. Among these manifestations, growth delay is one of the most common signs. Treatment with recombinant growth hormone (rhGH) is a widely used approach to stimulate growth in these patients.
Clinical Observation
We report the case of a 13-year-old boy, born by vaginal delivery with a birth weight of 1,800 g. He presents with characteristic dysmorphic features of Noonan syndrome, including low-set hairline and ears, hypertelorism, a triangular face, a mildly deformed chest, and widely spaced nipples. He measures 140.5 cm ($<$ -3 SD) and weighs 29 kg ($<$ -3 SD), indicating severe growth retardation. His genital examination revealed a penile length of 4.5 cm and testes measuring 2 $\times$ 1.5 cm. Biological investigations revealed an IGF-1 level of 169.2 ng/ml with a Z-score of -0.74. Bone age assessment showed a delay of 1 year and 2 months (bone age of 12 years). Additional investigations, including hypothalamic-pituitary MRI, renal ultrasound, and echocardiography, were normal. Furthermore, an insulin-induced hypoglycemia test showed no growth hormone deficiency. Treatment with recombinant growth hormone (rhGH) was initiated to stimulate growth. Regular follow-up is planned to evaluate the treatment response and monitor potential complications, particularly cardiac ones.
Discussion
Growth delay affects 50 to 70% of children with Noonan syndrome and often becomes apparent between the ages of 3 and 4 years. During childhood, these children generally have a height below the age-related norms. In adolescence, growth delay may worsen due to frequent pubertal delay in both sexes. Multiple factors can contribute to this growth delay, including growth hormone deficiency or IGF-1 resistance. In this context, treatment with recombinant growth hormone (rhGH) is a commonly used strategy to enhance growth. The results are generally positive, with notable improvements in growth velocity. However, cardiac abnormalities and the increased risk of hematological disorders often associated with Noonan syndrome require regular and thorough medical monitoring.
Conclusion
Growth delay in Noonan syndrome requires early and tailored management, along with regular follow-up, to improve growth and enhance the quality of life of patients.

Skeletal ciliopathy and short rib dysplasia: a case report with response to growth hormone therapy

Fawzia Alyafei[1], Ashraf Soliman[1], Shayma Ahmed[1], Carolin Beck[1], Nada Alaaraj[1], Noor Hamed[1] & Sohair Elsiddig[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Skeletal ciliopathies are a rare group of disorders affecting bone development. Short rib dysplasia is characterized by a narrow thorax, shortened ribs, and variable metaphyseal abnormalities. This report presents a child with a confirmed genetic diagnosis of KIAA0753-related skeletal ciliopathy and highlights diagnostic and therapeutic challenges.
Case Presentation
A 4-year-old Yamni boy was evaluated for short stature at 5 months, having normal birth parameters but falling below the 3rd centile in height by 5 months. He exhibited facial dysmorphism, short long bones, and a narrow thorax, though BMI and development were normal. His parents were first cousins with no family history of similar conditions. Genetic testing identified a homozygous pathogenic variant in KIAA0753, confirming short rib dysplasia, an autosomal recessive disorder associated with skeletal dysplasia and Joubert syndrome features. At 1 year, he developed severe obstructive sleep apnea (OSA) and underwent adenotonsillectomy at 14 months. By 23 months, his height was -4 SD, and growth velocity was 7 cm/year. GH stimulation testing revealed a peak GH level of 19 ng/ml. A GH trial (0.05 mg/kg/day) was initiated at 2 years, leading to a height improvement of 1.4 SD over 2.5 years, reaching -2.6 SD with normal growth velocity.
Management and Outcome
The patient continues GH therapy with ongoing height improvement and no side effects. His latest anthropometric data at 4 years showed a height SDS of -2.6, weight SDS of -1.08, and IGF-1 level of 201 mg/L (2 SD).
Discussion
Genetic evaluation is essential in cases of disproportionate short stature. GH therapy in skeletal dysplasias has shown variable efficacy. Kochar & Chugh (2020) reported modest height gains in achondroplasia and hypochondroplasia (Kochar & Chugh, 2020). Upadhyay *et al.* (2022) noted that GH therapy might exacerbate skeletal abnormalities in Dyggve–Melchior–Clausen syndrome (Upadhyay *et al*., 2022). Despite uncertainties, our case supports potential GH benefits in skeletal ciliopathies.
Conclusion
Early diagnosis, genetic testing, and individualized GH therapy may optimize outcomes in skeletal ciliopathies. Continued GH therapy is recommended until the final adult height is reached, though further research is needed to refine treatment protocols.

Introduction
Microcephalic osteodysplastic primordial dwarfism type II (MOPD II) is characterized by severe growth retardation, microcephaly, low to normal intelligence, distinctive facial features, and severe short stature. This study examines the clinical features of four cases with heterozygous mutations in the pericentrin (*PCNT*) gene.
Cases
Case 1: A 7-year-5-month-old male, born at 39 weeks with a birth weight of 2750 grams (-1.68 SD), presented with short stature. His height was 114.4 cm (-1.88 SD), weight 18.3 kg (-1.84 SD), head circumference 48.5 cm (-2.58 SD), and he was prepubertal with a growth velocity of 5.2 cm/year. **Case 2** An 8-year-old male, born at 38 weeks with a birth weight of 2000 grams (-3.67 SD), presented with short stature. His height was 113.3 cm (-2.65 SD), weight 17 kg (-2.68 SD), head circumference 50.5 cm (-1.45 SD), and he was prepubertal with a growth velocity of 4.5 cm/year. **Case 3** A 6-year-11-month-old female, born at 33 weeks + 5 days with a birth weight of 2080 grams (0.15 SD), was under follow-up for thyroid agenesis. Her height was 106.3 cm (-2.93 SD), weight 16 kg (-2.39 SD), head circumference 49.5 cm (-1.34 SD), and she was prepubertal with a growth velocity of 4.8 cm/year. Genetic analysis revealed heterozygous mutations in PCNT and MEN1 genes. **Case 4** A 10-year-9-month-old female, born at 36 weeks with a birth weight of 1500 grams (-3.32 SD), was under follow-up for celiac disease. Her height was 126.4 cm (-2.56 SD), weight 26.5 kg (-1.69 SD), head circumference 48.6 cm (-3.12 SD), and she was at Tanner stage 2. Her growth velocity was 5.3 cm/year. After three years of growth hormone therapy (0.045 mg/kg/day), her final height was 145 cm (-2.4 SD). All cases had heterozygous *PCNT* mutations, normal liver, kidney, and thyroid function tests, and negative celiac antibodies.
Conclusion
Heterozygous mutations in the *PCNT* gene, compared to homozygous or compound heterozygous cases, are associated with milder short stature but can still lead to low birth weight and, in some cases, microcephaly. Genetic analysis is critical in patients with short stature, SGA birth, microcephaly, or a family history of pathological short stature. According to current literature, pediatric cases with heterozygous *PCNT* mutations have not been previously reported. Comprehensive evaluations of the efficacy and safety of growth hormone therapy will play a key role in improving future treatment approaches.

Beckwith wiedemann syndrome associated with transient typical features of classical congenital adrenal hyperplasia: a case report

Elizabeth Oyenusi[1,2], Olaide Elemo[2], Blessing Kene-Udemezue[2], Khadijah Oleolo-Ayodeji[2], Oluwadamilola Oladipo[2], Osayanmon Chiemeke[2], Olaolu Moronkola[2] & Abiola Oduwole[1,2]
[1]College of Medicine, University of Lagos, Lagos University Teaching Hospital, Paediatrics, Lagos, Nigeria; [2]Lagos University Teaching Hospital, Paediatrics, Lagos, Nigeria

Introduction
Beckwith–Wiedemann syndrome (BWS) is a rare syndrome with features of overgrowth, macroglossia, abdominal wall defects, hemihypertrophy and enlarged abdominal organs. It is caused by genetic or epigenetic defects within the chromosome 11p15.5 region which contains imprinted genes that are strong regulators of fetal growth. Molecular diagnosis of BWS is important because of different degrees of predisposition to embryonal tumours in various subtypes. Presentation of BWS is widely variable and may be associated with adrenal involvement. Congenital adrenal hyperplasia (CAH) is the leading cause of atypical genitalia in the female newborn. An elevated blood level of 17-hydroxyprogesterone (17-OHP) indicates 21-hydroxylase deficiency, and is used in neonatal screening of CAH to prevent adrenal crisis and early neonatal death. Previously, BWS was not a recognized cause of false positives for CAH screening but this has been reported recently in some cases of BWS. This case is presented because of a similar presentation.
Case description
A late preterm (36weeks gestational age) female presented at the 3rd hour of life with anterior abdominal wall defect and swelling. Examination revealed coarse facial features, macroglossia, omphalocoele major, prominent labia majora with hyperpigmented and enlarged clitoris. Cardiorespiratory examination was essentially normal. Weight was (3600g) greater than the 97th percentile for age and sex, with length (50cm) and occipitofrontal circumference (32cm) at 95th and 50th percentiles respectively. No hemihypertrophy was noticed. Bedside blood glucose was low (30mg/dl[1.7mmol/l]). Other serum investigations revealed low cortisol, elevated testosterone and 17-hydroxyprogesterone. Pelvic ultrasound scan (USS) showed female internal genitalia suggesting CAH. She was commenced on hydrocortisone while omphalocele major was managed conservatively. There was no enlargement of the adrenal glands and no tumours seen on abdominal USS. Genetic analysis showed *hypomethylation at KCNQ1OT1:TSS-DMR (IC2) within 11p15.5* confirming a diagnosis of BWS. Clitoromegaly resolved at 6 months of age with normal pigmentation of the external genitalia. Steroids have been tailed off and repeat cortisol, testosterone and 17-hydroxyprogesterone are normal. Patient is being monitored as per the protocol for BWS with IC2 mutation (clinical assessment and USS in response to signs and/or symptoms or parental concern).
Conclusions
Beckwith-Wiedemann syndrome can present with features suggestive of CAH. Monitoring and genetic testing is essential for confirmation. In view of risk of adrenal crisis in infants with CAH, it may be better to err on the side of caution by commencing hydrocortisone especially when genetic screening is unavailable and tail off therapy if no longer needed.

Differences in age, gender, and hormonal immunohistochemical profiles among patients with acromegaly and non-functioning pituitary adenomas

Hamza El Hadi[1], Rohith Illuri[1], Wengy Gu[1], Olivia Miska[1], Anna Fast[1], Eric Suero Molina[2], Barak Akkurt[3], Jonel Trebicka[1] & Elena Vorona[1]

[1]Münster University Hospital, Department of Gastroenterology, Hepatology, Endocrinology, Infectiology, Münster, Germany; [2]Münster University Hospital, Department of Neurosurgery, Münster, Germany; [3]Münster University Hospital, Department of Clinical Radiology, Münster, Germany

Introduction
Acromegaly is a rare disorder resulting from chronic hypersecretion of growth hormone (GH), typically due to a pituitary adenoma. Conversely, non-functioning pituitary adenomas (NFPAs) are among the most common subtypes of adenohypophyseal tumors, characterized by the absence of clinically significant hormone secretion. Data regarding gender distribution and mean age at diagnosis for these conditions remain inconclusive.
Aim
The study aimed to assess the differences in gender distribution, age, tumor volume, and hormonal immunochemical profiles (IHC) between patients with acromegaly and NFPA at diagnosis.
Methods
We retrospectively analyzed 81 patients diagnosed with acromegaly and 76 patients with NFPAs referred to our Clinic's Endocrinology and/or Neurosurgery Units between 2018 and 2019. Immunohistochemical analysis of adenohypophyseal hormone expression was available in tumor tissue samples from 53 patients with acromegaly and 29 with NFPA.
Results
Patients with acromegaly were diagnosed at a younger age than those with NFPAs (median [IQR]: 43 [39–56] years vs. 50 [40–63] years; $P = 0.034$), while no significant difference in gender distribution was observed between the groups. The median tumor volume in patients with NFPAs (3.8 [1.4–8.4] cm^3) was significantly larger than that in patients with acromegaly (1.4 [0.7–4.8] cm^3; $P = 0.004$). Immunohistochemical analysis revealed that adenomas in acromegalic patients were predominantly plurihormonal, with growth hormone and prolactin being the most frequently co-expressed hormones. In contrast, NFPAs showed most commonly negative hormonal staining. Among patients with acromegaly, males were diagnosed at a younger age than females (median [IQR]: 42.0 [39–50] years vs. 47.0 [38.5–60.5] years; $P = 0.041$). Interestingly, in patients with NFPA, both genders showed no significant differences regarding median age at diagnosis and tumor volume.
Conclusion
Our findings indicate that male patients with acromegaly are diagnosed at an earlier age than females, despite both having no significant differences in pituitary tumor volumetry. This may reflect an earlier onset or more prominent presentation of disease-related signs in males. Additionally, positive immunostaining for growth hormone and prolactin co-expression was a distinctive feature of pituitary tumor cells in patients with acromegaly.

Socio-demographic profile in adult patients with turner syndrome

Nassim Ben Hadj Slama[1], Imen Halloul[1], Lamys Abbes[1], Ghachem Aycha[1], Ghada Saad[1] & Yosra Hasni[1]
[1]Farhat Hached University Hospital, Endocrinology, Sousse, Tunisia

Background
Turner syndrome (TS) is characterized by a great variability of clinical manifestations caused by a total or partial loss of X-chromosome. TS is also associated with cognitive and psychosocial impairment
Objective
To describe the socio-demographic profile of adult patients with Turner Syndrome.
Patients and Methods
This was an observational case series with a retrospective chart review of 33 patients diagnosed with TS who are aged over 15 years. These patients were followed at the Farhat Hached University Hospital Sousse.
Results
The mean age of the patients was 25.6‡ 10.6 years, with a mean age at diagnosis of 16.3 ‡ 6.4 years. Chromosomal abnormalities were categorized as follows: monosomy X in 54.4%, solely structural abnormalities in 18.2%, and monosomy with structural abnormalities in 27.3%. Parental consanguinity was observed in 31.3% of the cases and was more frequent among patients with mosaicism. The mean maternal age at birth was 27.57 # 4.27 years, with advanced maternal age noted in only one patient. At the legal age of marriage, 88% of the patients were single, and 12% were married. Regarding educational attainment, 21.2% had completed primary education, 63.6% had completed secondary education, and 15.2% had attained higher education. A higher level of education was noted in patients with mosaicism (27.5% vs. 9.5% in those with homogeneous anomalies), although this difference was not statistically significant. Nine percent of the patients had hearing loss and used hearing aids, while only one patient exhibited cognitive decline.
Discussion
Patients with TS face a multitude of social challenges, including significant difficulties with interpersonal relationships and academic performance, which can profoundly impact their overall quality of life. Furthermore, some studies have emphasized the challenges these patients encounter in effectively identifying emotions and understanding the mental states of others. This inability can lead to misunderstandings in social interactions and can hinder the development of meaningful relationships. Additionally, specific learning difficulties, such as challenges with spatial reasoning or mathematics, are reported to be prevalent among individuals with TS. These factors necessitate not only a comprehensive approach to their medical care but also the establishment of a supportive and understanding social and educational environment conducive to their unique needs. Creating tailored educational programs that focus on emotional intelligence and social skills may significantly benefit patients as they navigate their educational and social landscapes.

GH therapy in patients with empty sella syndrome and growth hormone deficiency: two cases with transition to weekly treatment

Sokratis Katsoudas[1], Ioannis Pichlinski[1], Evangelia Tsitsekli[2], Nikolitsa Techlemetzi[1], Polychroni Ioulia[2] & Paraskevi Zosi[1]
[1]General Hospital Of Nikaia, Pediatric Endocrinology Unit, Nikaia, Greece; [2]Private Pediatric Endocrinology Unit, Neo Hrakleio, Greece

Introduction
Empty Sella Syndrome (ESS) is a rare condition in children, often associated with growth hormone (GH) deficiency. We present two pediatric cases of ESS diagnosed with GH deficiency who demonstrated significant growth improvement after receiving recombinant GH (rGH) therapy. Both patients were transitioned to weekly GH therapy at some point through their treatment, showing sustained positive outcomes.
Methods
Case 1 involves a 12-year and 6-month-old male who presented with short stature and rapid decline in height velocity, showing a growth rate of 2.3 cm/year. Medical and birth history were unremarkable. His height was 138.5 cm ($\leq$2nd percentile), and he was in Tanner stage 2-3, with a testicular volume of 7 ml. GH stimulation tests revealed peak GH levels of 6.8 ng/ml (glucagon) and 7.6 ng/ml (L-Dopa), with an IGF-1 of 182 ng/ml. MRI confirmed ESS. GH treatment was started, and the results are shown in table 1. Case 2 involved a 12-year and 10-month-old male referred due to short stature. His height was 140 cm (3rd percentile), weight was 29 kg, and height velocity was 3.1 cm/year. He had a 2-year history of well-managed hypothyroidism, and unremarkable birth history. GH stimulation tests revealed peak GH levels of 6.6 ng/ml (glucagon) and 6.0 ng/ml (L-Dopa). MRI confirmed ESS. GH treatment was started, and the results are shown in table 1.
Results
Both patients showed significant growth improvement with rGH. In Case 1, height increased by 13 cm in 18 months. In Case 2, height increased by 26 cm in 2 years and 7 months. Transitioning to weekly GH therapy midway through treatment maintained sustained or growth improvements in both cases. Interestingly, case 2 benefited more from the weekly GH treatment due to improved compliance.

Table 1. Case 1

Date of Measurement	Age (years)	Height (cm)	Bone Age (years)
8/6/23 **Beginning of treatment**	12+6/12	138.5	12
30/11/23	12+11/12	142.5	12+9/12
3/6/24 **Transition to weekly GH**	13+5/12	145.5	13+3/12
5/12/24	13+11/12	151.5	13+6/12

Table 1. Case 2

Date of Measurement	Age (years)	Height (cm)	Bone Age (years)
3/5/22 **Beginning of treatment**	12+9/12	140	11+6/12
1/11/22	13+2/12	144	12
2/5/23	13+8/12	149	13
30/11/23	14+4/12	155	14
30/5/24 **Transition to weekly GH**	14+9/12	160	15
2/12/24	15+3/12	166	15+3/12

Conclusion
These cases show the effectiveness of recombinant GH therapy in promoting significant growth in pediatric ESS patients with GH deficiency, with sustained or even improved benefits following the transition to weekly GH.

Evaluating the IGF-1 generation test as a predictor of growth outcomes across pediatric growth disorders"

Fawzia Alyafei[1], Ahmed Elawwa[1], Aml Sabt[2], Shayma Ahmed[1], Nada Alaaraj[1], Noor Hamed[1] & Ashraf Soliman[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]sidra medicine, doha, Qatar

Background
IGF-1 generation is valuable for assessing early and long-term growth outcomes, but its utility varies depending on the disorder and degree of GH sensitivity.
Objective of the Review
To evaluate the predictive and diagnostic significance of the IGF-1 generation-test in determining growth response and GH sensitivity in growth disorders.
Methods
Data were compiled from six studies, encompassing over 800 pediatric patients with conditions such as Growth Hormone Deficiency (GHD), Idiopathic Short Stature (ISS), and GH insensitivity. Studies assessed the correlation between IGF-1 generation, early IGF-1 responses during GH therapy, and long-term growth outcomes.
Results
Table.
1. Predictive Value: Early increases in IGF-1 levels during GH therapy strongly correlated with positive long-term growth outcomes, as highlighted by studies with larger sample sizes-(Smyczynski *et al*., 2013; Blum *et al*., 1993).
2. GH Sensitivity: Changes in IGF-1 levels during therapy positively correlated with improvements in height, confirming GH sensitivity across various conditions-(Kim *et al*., 2021).
3. Utility in Diagnosing GH Insensitivity: The test has limitations in detecting mild GH insensitivity, with some variability in responses among GHD and ISS patients-(Coutant *et al*., 2012; Buckway *et al*., 2001).
4. Combined Markers: IGFBP-3 levels at baseline and during therapy enhance the predictive utility of the test, particularly in short stature children-(Perez-Colon *et al*., 2018).
Discussion
The IGF-1 generation test is a valuable tool for predicting long-term growth responses to GH therapy and assessing GH sensitivity. Its strengths lie in strong early correlations with growth outcomes, but its limitations in detecting mild GH insensitivity highlight the need for additional markers like IGFBP-3.
Conclusions
The IGF-1 generation test is a reliable marker for predicting GH therapy outcomes and assessing GH sensitivity in children. Its utility is enhanced when combined with additional biomarkers like IGFBP-3, although limitations in diagnosing mild GH insensitivity must be considered. Table: Predictive and Diagnostic Findings from IGF-1 Generation Test Across Growth Conditions"

Table 1. Predictive and Diagnostic Findings from IGF-1 Generation Test Across Growth Conditions

Condition	Main Findings
Short Stature and GHD	Early IGF-1 and IGFBP-3 increases correlate with long-term growth response to GH therapy.
GHD and ISS	Early IGF-1 increases predict better growth outcomes over time.
Short Stature (Various Conditions)	Positive IGF-1 changes during therapy correlate with height improvement.
Mild GH Insensitivity (GHIS)	Test has limitations in detecting mild GH insensitivity.
GH Responsiveness (GHD, ISS, GHIS)	GH sensitivity varies; IGF-1 generation test reflects dose-dependent response.
Short Stature with Low IGF-1	Baseline IGF-1 and IGFBP-3 predict growth response to GH or IGF-1 therapy.

A novel IGF1R variant in a patient with short stature in qatar

Fathima Koolikkad Mohammed[1,2], Zainab Jan[1], Umm-Kulthum Ismail Umlai[1], Dinesh Velayutham[3], Noor Hamed[4], Hajar Dauleh[5], Khalid Hussain[5,6] & Puthen Veettil Jithesh[1]
[1]College of Health and Life Sciences, Hamad Bin Khalifa University, Doha, Qatar; [2]Communicable Disease Center, Hamad Medical Corporation, Doha, Qatar; [3]Qatar Precision Health Institute, Doha, Qatar; [4]Department of Pediatrics, Division of Endocrinology, Hamad General Hospital, Doha, Qatar; [5]Division of Endocrinology, Department of Pediatrics, Sidra Medicine, Doha, Qatar; [6]Division of Endocrinology, Department of Pediatric Medicine, Weill Cornell Medicine-Qatar, Doha, Qatar

Introduction
Short stature (SS) is a common cause of referral to pediatric endocrinology clinics and can arise from a range of underlying causes. Among the endocrine disorders leading to SS are growth hormone and Insulin Growth Factor-1 (IGF-1) signaling defects. Genetic testing plays a crucial role in uncovering variants in genes, such as type 1- insulin-like growth factor receptor gene (*IGF1R*), associated with SS to tailor personalized treatment options. Here we report a novel missense variant in *IGF1R* in a SS patient in Qatar.
Case Presentation
A female patient presented with failure to thrive, SS, and microcephaly at 10 years of age. She was born SGA with birth weight of 2.3kg at term. At evaluation, her height was 121.2cm (-2.89 SD) and weight was 19.15kg (-3.89 SD). Her serum IGF-1 level was 47.7 nmol/L (Normal range: 9.9-71.8) and the growth hormone stimulation test was normal. She has a family history of SS on the paternal side. Whole genome sequencing (WGS) and bioinformatics analysis identified a novel missense heterozygous variant c.2240A>G (p.Asn747Ser) in *IGF1R*. This variant segregated in an autosomal dominant manner, has a Combined Annotation-Dependent Depletion (CADD) score of 22.4, and was predicted to be 'disease-causing' by Mutation Taster. Protein-protein docking of the mutated and wild-type IGF1R with interactor proteins using HADDOCK found that mutant IGF1R showed decreased affinity for IGF1 and higher binding for IGF2 compared to the wild type, thus disrupting the normal IGF1 signaling and leading to IGF1 resistance.
Conclusion
We identified a novel c.2240A>G missense variant in *IGF1R* in SS patient. Her phenotype is consistent with those findings reported in the literature for *IGF1R* mutations. This emphasizes the importance of WGS in SS patients and examining *IGF1R* variants in patients with impaired growth, especially those with elevated or normal levels of circulating IGF-1 in the bloodstream.

Effect of urea ingestion on growth hormone levels in healthy adults – An analysis of a double-blind, randomized, placebo-controlled cross-over trial

Friederike Riehle[1], Sven Lustenberger[1], Emanuel Christ[1], Sophie Monnerat[1], Cihan Atila[1] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Basel, Switzerland

Introduction
Growth hormone (GH) deficiency is commonly diagnosed using stimulation tests such as insulin hypoglycemia or the GH-releasing hormone-arginine test. However, these tests are burdensome and require intravenous access. Macimorelin, an oral GH stimulation test, offers an alternative but is unavailable in many countries, highlighting the need for accessible, non-invasive oral options. Urea, the end product of protein metabolism, is commonly used as an oral treatment for hyponatremia. Since GH promotes protein synthesis and reduces urea production, we hypothesized that high urea levels may stimulate GH secretion via feedback regulation. Therefore, this study investigates whether oral urea could serve as an alternative stimulation test for diagnosing GH deficiency.
Methods
This is a secondary analysis of a double-blind, randomized, placebo-controlled cross-over trial in 22 healthy adults. Participants presented for two visits in the morning after an overnight food fasting and a two-hour fluid restriction. They received a single weight-adapted dose of oral urea (0.5 g/kg body weight; minimum 30g, maximum 45 g) or placebo in random order. Serum GH was measured at baseline, 60 and 120 minutes. The primary endpoint was the serum GH levels after ingestion of urea vs placebo.
Results
Of 22 healthy adults, 12 (55%) were female, with a median [IQR] age of 27 years [26, 32] and a body mass index of 23.3 kg/m^2 [21.6, 25.8]. Before urea ingestion, GH at baseline was 0.83 µg/l [0.28, 5.75], decreased to 0.38 µg/l [0.20, 2.46] after 60 minutes, and increased to 1.00 µg/l [0.71, 2.34] after 120 minutes. Before placebo ingestion, GH at baseline was 0.93 µg/l [0.38, 5.34], decreased to 0.38 µg/l [0.16, 1.51] after 60 minutes, and increased to 0.73 µg/l [0.18, 1.59] after 120 minutes.

Conclusion
Our study demonstrated no relevant changes in serum GH after the ingestion of urea in comparison with placebo. These findings suggest that urea does not stimulate GH secretion and cannot be used as a stimulation test for GH deficiency.

An early diagnosed leri-weill dyschondrosteosis case caused by unusual genetic results

Beray Selver Eklioğlu[1,2], Fatma Nur Demirkol[1], Emine Goktas[3] & Mehmet Emre Atabek[1]
[1]Necmettin Erbakan University, Faculty of Medicine, Department of Pediatric Endocrinology, Konya, Türkiye; [2]Necmettin Erbakan University Faculty of Medicine, Konya, Türkiye; [3]Necmettin Erbakan University, Faculty of Medicine, Department of Genetics, Konya, Türkiye

Introduction
The SHOX gene (Short stature HOmeoboX-containing gene) regulates height growth. It is located in the pseudoautosomal region of the short arms of the X and Y sex chromosomes and encodes a transcription factor called SHOX protein. Haploinsufficiency of the SHOX gene is responsible for the etiology of many diseases such as idiopathic short stature, Turner Syndrome, and Leri-Weil dyschondrosteosis. We present a rare case of Leri-Weil dyschondrosteosis diagnosed at an early age due to a mutation in the SHOX gene in a patient presenting with disproportionate short stature.
Case Presentation
A five-month-old male infant presented with disproportion in the arms and legs and short stature. He was born at 38 weeks gestation, weighing 3700 grams, to a 36-year-old mother in her second pregnancy (second live birth). There was no significant past medical or family history. On physical examination, his weight was 5250 grams (-2.61 SDS), height was 57.3 cm (-3.48 SDS), and head circumference was 38.5 cm (3.43 SDS). His mother's height was 155 cm, his father's height was 176 cm, and his target height was 172 cm(-0.19 SDS). His forearm length was 9 cm, and his upper arm length was 10 cm and had mesomelic shortening. No mutation was detected in the DNA sequence analysis that would explain his short stature. Cytogenetic analysis (karyotype) of the patient revealed a deletion of the SHOX gene on the Y chromosome. The patient's cytogenetic analysis was reported as mos46XY, del(Y)(p11.3)del(Y)(q11.2), t(14;16)(p11.2q11.2)(15)/45,X, t(14;16 p11.2;q11.2)(15). Cytogenetic analyses of both parents were performed. The mother's genetic analysis was reported as 46 XX, t(14:16)(p11.2;q11.2), indicating that she was a carrier of the translocation. Based on these genetic findings, the patient was diagnosed with Leri-Weil dyschondrosteosis. At 1 year and 2 months old, the patient's weight was 6.7 kg (-4.76 sds), height was 64 cm (-5.51 SDS). Growth hormone therapy was initiated. At 1 year 8 months of age the patient's weight was 7.5 kg (-4.58 sds), height was 70 cm (-4.39 SDS) by using growth hormone therapy 2 months.
Conclusion
Leri-Weil Dyschondrosteosis is a skeletal dysplasia characterized by mesomelic shortening. It should be considered in the differential diagnosis of patients presenting with disproportionate short stature. Early determination of the etiology of short stature and initiation of growth hormone therapy may lead to gains in final adult height.

The clinical and mutational spectrum of ulnar-mammary syndrome: two case reports and literature review

Xiaoyan Wang[1]
[1]children's hospital of soochow university, suzhou, China

Objective
The aim of this study was to investigate the clinical and genetic characteristics of three cases of short stature caused by the *GHSR* gene mutation.
Methods
A retrospective analysis was conducted on the clinical data and genetic test results of three cases of short stature caused by the *GHSR* gene mutation. The patients were followed up at the Department of Endocrinology Genetics and Metabolism of the Children's Hospital of Soochow University. A literature search (search terms included "*GHSR*" and "short stature") for recently published studies was completed using the China National Knowledge Infrastructure database, WanFang database, PubMed, and the Human Gene Mutation Database.
Results
The peak value of growth hormone provocation test in two cases was >10 ng/ml, and the height of two patients was improved after recombinant human growth hormone therapy. One untreated patient was followed up until lifelong height was reached, and the patient remained with a short stature.
Conclusion
The peak value of growth hormone provocation test in patients with *GHSR* gene variants may be >10 ng/ml, these patients may have precocious puberty, and short stature caused by the *GHSR* gene mutation can be treated with growth hormone.

Empty sella syndrome and growth hormone deficiency in a 6-year-old boy with short stature

Bogdan Pascu[1] & Carla Ciobanu[1]
[1]INSMC Alessandrescu Rusescu, Pediatric Endocrinology, Bucharest, Romania

Introduction
Growth deceleration in children may indicate an underlying condition. One such condition is Empty Sella Syndrome (ESS), a radiological finding caused by the herniation of the subarachnoid space into the sella turcica, leading to pituitary gland flattening. While rare in children and often an incidental MRI finding, ESS can be associated with hormonal deficiencies, particularly growth hormone deficiency (GHD), which contributes to growth impairment.
Case Report
A 6-year-old boy was referred to the endocrinology clinic for growth monitoring due to concerns about his growth velocity. Over the past year, his height declined from -1.83 standard deviations (SD) to -2.40 SD, with a growth velocity of 3 cm/year—below the expected rate for his age. His medical history included left cryptorchidism, surgically corrected in infancy, with no family history of endocrine disorders. On physical examination, his height was 105 cm (-2.40 SD, $<$3rd percentile), below the mid-parental height with a Z-score of -2.22. His weight was 23 kg (BMI $=$ 18.6, 95th percentile). He was Tanner stage I, with no other systemic abnormalities or developmental delays. Laboratory tests revealed low IGF-1 (19.3 ng/ml; normal: 36.6–156) and low IGFBP-3 (1.24 µg/ml; normal: 1.94–5.19), with normal thyroid, ACTH, cortisol, and prolactin levels, ruling out other pituitary axis dysfunctions. Bone age assessment showed a 2-year delay, and karyotype analysis confirmed a normal male karyotype. A clonidine stimulation test demonstrated a poor GH peak of 1.77 ng/ml, confirming growth hormone deficiency. MRI revealed an extension of the subarachnoid space into the pituitary fossa, compressing and flattening the pituitary gland—a characteristic finding of ESS. The patient was diagnosed with growth hormone deficiency secondary to Empty Sella Syndrome and was started on recombinant human growth hormone at a dose of 0.025 mg/kg/day (0.55 mg/day). After three months of treatment, he demonstrated significant improvement, with a height increase of 5.5 cm, reaching 110.5 cm. His Z-score improved by approximately 1 SD (from -2.49 to -1.59), reflecting notable catch-up growth. He will continue to be closely monitored for growth response and other potential pituitary hormone deficiencies.
Conclusions
ESS is rare in children, presenting as either an incidental finding or with hormonal deficiencies. Growth hormone deficiency, the most common pituitary disorder in ESS, affects 12% to 60% of patients. Early diagnosis and timely growth hormone therapy are essential for optimizing growth outcomes in affected children.

JOINT2702

A clinical case of rasopathies caused by a mutation in the SHOC2 gene

Zinaida Zyuzikova[1], Nataliya Volevodz[1] & Valentina Peterkova[1]
[1]Endocrinology Research Center, Moscow, Russian Federation

RASopathies is a multisystem genetic disorder characterized by such clinical manifestations as growth retardation, craniofacial and skeletal anomalies, varying degrees of intellectual disability, congenital heart defects and a predisposition to myeloproliferative disorders. Girl E., 5 years old, from the 2nd pregnancy, during the ultrasound examination at the 1st screening an expansion of the collar area nuchal was revealed, at the 20th week of gestation - chorioangioma of the placenta. The 2nd birth

was by cesarean section at the 38th week of gestation. At birth, body weight was 3120 g (0.06SD), body length was 48 cm (-0,35SD), according to the Apgar scale 8/9 points. The early neonatal period was unremarkable. Family history of endocrinopathies is not burdened, target height is 163.5 cm, SDS of target height: 0.025 SD. At 3 months, the girl suffered from mixed-etiology sepsis and iron-deficiency anemia. She is being observed by an ophthalmologist with the following diagnosis: OU - compensated convergent sensory, unilateral OD strabismus, accommodative. High myopia OD. Lesion of the central section of the visual analyzer, partial atrophy of the optic nerve OD > OS. OD - madarosis, trichiasis, deformation of the upper eyelid margin. OS - partial ptosis of the upper eyelid stage 1, compensated. Congenital renal defects are excluded. A functioning oval window up to 2 mm remains. Growth retardation is observed from an early age. Karyotype: 46,XX. During examination at 4 years, blood tests showed IGF-1 - 65.8 ng/ml (SDS IGF-1 - 0.82), no data for deficiency of other tropic hormones were obtained. At the age of 5 years his height was 98.2 cm (- 2.4 SD), his weight was 16.5 kg (BMI + 1.1 SD), Tanner 1. Phenotypic features were noticed: low-set ears, left eyelid ptosis, strabismus, scaphocephaly, hoarse voice, short neck, chubby cheeks, dark skin, light, sparse, falling out hair. Bone age corresponded to chronological age. Additional molecular genetic testing was performed: a mutation in the SHOC2 gene (chr10:112724120A > G) was detected in a heterozygous state, leading to a substitution of an amino acid in position 2 of the protein [NM 001324336.1:c.4A > G; p.(Ser2Gly)]]. The presented clinical case demonstrates the classic phenotype of RASopathies with loss of anagen, caused by a pathogenic variant in the SHOC2 gene. The issue of treatment with somatropin remains controversial due to the lack of published randomized clinical trials with long-term observation of patients until the period of achieving final height.

Pharmacological treatment of growth in boys with delayed or slow progression of puberty

Gunduz Ahmadov[1]
[1]Azerbaijan Medical University, pediatric endocrinology, Baku, Azerbaijan

At puberty, male sexual differentiation restarts with nightly pulsatile stimulating impulses of hypothalamic gonadotropin-releasing hormone to the pituitary gland, which releases luteinizing and follicle-stimulating hormones. This nocturnal increase in gonadotropins results in growth, too. The aim of the research work was to correct the height of children the use of testosterone enanthate (TE), 50 mg intramuscularly (i.m.)/month, for the treatment of boys with delayed puberty or slow progression to induce puberty. For this purpose, 25 boys were examined. The average age of children was 13.9 ± 1.03 years. In children, they were evaluated according to the Tanner table and measured their height, body mass and injected 0.2 ml of Omnadren-250 (testosterone, mixture of esthers). Children took this drug once a month. The boys are called back after 3 months for clinical evaluation and to follow up on pubertal and growth progression. The boys were examined by study doctors twice before the study, at inclusion, and after 3 months. After 3 months, their physical development was assessed. Physical development indicators of children are given in table 1 below. The results show that 50 mg (0.2 ml) of TE administered once every months for 3 months can be used to induce growth development in boys with delayed or slow progression of puberty, while did not record an honest increase in body mass.

Table 1. Indicators of physical development of children

Parameters	Before	After	p
Height	144,4 ± 4,83	147,1 ± 4,45	p < 0,0001
Weight	36,5 ± 7,03	39,0 ± 6,62	p > 0,05
SD Height	-2,3 ± 0,25	-2,1 ± 0,23	p < 0,0001
SD Weight	-0,9 ± 1,39	-0,7 ± 1,24	p > 0,05
BMİ kq/m^2	17,5 ± 3,10	17,9 ± 2,77	p > 0,05

Spontaneous pregnancy in a patient with turner syndrome

Nassim Ben Hadj Slama[1], Imen Halloul[1], Lamys Abbes[1], Ghachem Aycha[1] & Ghada Saad[1]
[1]Farhat Hached University Hospital, Endocrinology, Sousse, Tunisia

Introduction
Turner syndrome (TS) is the most common chromosomal abnormality in women, occurring in approximately 1 in 2,500 live births. Spontaneous pregnancies in individuals with TS are rare, with an incidence ranging from 1.8% to 7.6%. We report a case of three spontaneous pregnancies in a patient with TS.
Observation
A 31-year-old female with no significant past medical or family history presented for evaluation. She reported menarche at the age of 12, with subsequent regular menstrual cycles. Physical examination did not reveal any evidence of growth retardation or dysmorphic features typically associated with TS. The patient had three spontaneous pregnancies throughout her reproductive life. The first pregnancy was terminated in the second trimester after the discovery of a malformation syndrome. Chromosomal analysis confirmed a diagnosis of Turner's mosaic syndrome, with a karyotype of 45,×/46, XX. Further evaluation for common comorbidities associated with TS, including cardiac anomalies, was negative, with no evidence of cardiac malformations. The patient then conceived two more times, with both pregnancies progressing without significant complications. Both were carried to term, delivered vaginally, and resulted in the birth of two healthy female neonates, each with a normal karyotype (46,XX).
Discussion
TS is strongly associated with hypergonadotropic hypogonadism and ovarian dysgenesis, which typically result in infertility in most affected individuals. The issue of fertility in individuals with TS has been extensively studied. Cryopreservation of mature oocytes and embryos is a well-established method for fertility preservation, while cryopreservation of ovarian tissue represents a promising, though still investigational, approach, with a growing number of successful live births. Spontaneous pregnancies, such as those observed in the present case, are rare and are more commonly seen in individuals with mosaic forms of Turner syndrome or those with distal X chromosome deletions. Cardiac malformations are considered absolute contraindications to fertility treatments due to the substantial maternal and fetal risks involved. Pregnancies in individuals with TS are associated with a significantly increased risk of miscarriage and other obstetric complications, which necessitates vigilant monitoring by a multi-disciplinary medical team to optimize both maternal and fetal outcomes.

Shaff yang syndrome and growth hormone therapy

Julita Nocoń-Bohusz[1] & Robert Śmigiel[1]
[1]Wroclaw Medical University, Department of Pediatrics Endocrynology Diabetology and Metabolic Disorders, Wrocław, Poland

Introduction
Schaaf-Yang syndrome (SYS) is the result of loss of function of the MAGEL2 gene (point mutations in the gene) within chromosome 15q11-13. A microdeletion or paternal disomy (pUPD) region of chromosome 15q11-13 is the cause of the better known Prader-Willi syndrome (PWS). Due to the genetic basis, both syndromes show a high similarity of symptoms in infancy, i.e. hypotonia, feeding problems, sleep apnoea, hypogonadism, but also intellectual developmental delay and low stature. Autism spectrum disorders and joint contractures are additionally observed in SYS patients. Studies show undeniable benefits of rhGH therapy in PWS patients during childhood, as well as after end of growing. Benefits include, in addition to improved growth rate, improved body composition, improved lipid profile, increased bone mineral density and improved mental status along with quality of patientś life.
Aim
This study presents 4 children with genetically confirmed Schaaf-Yang syndrome. Health problems observed in the children were hypotonia, respiratory distress in the neonatal period, hypoglycaemia, psychomotor developmental delay, low stature and epilepsy, autism, joint contractures. Three children were qualified for growth hormone treatment under the programme for children with somatotropin hypopituitarism. We will compare anthropometric parameters including growth rate during therapy, biochemical parameters of blood, lipid, endocrine and carbohydrate metabolism, overall psychomotor development of the children and the impact of growth hormone treatment on family quality of life.
Conclusions
1. Growth GH deficiency has been documented in Schaaf-Yang syndrome, therefore it is reasonable to treat these children with growth hormone from early life. 2. The validity of the child's eligibility for growth hormone treatment from a different programme than for children with SNP based on the genetic diagnosis of the disease (no need for pituitary stimulation tests and radiological imaging) should be considered. 3. Given the similarity of SYS with PWS and the benefits of growth hormone therapy taking into account the promotion of growth and the

positive metabolic impact, it is advisable to determine the optimal initial therapeutic dose of rhGH.

Design of a randomized, multicentre, phase 2 study of vosoritide in children with turner syndrome, noonan syndrome, or short stature homeobox-containing gene (SHOX) deficiency

Andrea Low[1], Roopa Kanakatti Shankar[2], Bradley Miller[3], Lawrence Silverman[4], Klaus Mohnike[5], Ron Rosenfeld[6], Ian Sabir[7], Alice Huntsman Labed[7], Mingjin Li[1] & Andrew Dauber[2]
[1]BioMarin Pharmaceutical Inc., Novato, United States; [2]Children's National Hospital, Washington DC, United States; [3]Division of Endocrinology, Department of Pediatrics, University of Minnesota Medical School, Minneapolis, United States; [4]Division of Pediatric Endocrinology, Goryeb Children's Hospital, Atlantic Health System, Morristown, United States; [5]Otto-von-Guericke-Universität, Magdeburg, Germany; [6]Department of Pediatrics, Oregon Health & Science University, Portland, United States; [7]BioMarin (UK) Ltd, London, United Kingdom

Turner syndrome, Noonan syndrome, and short stature homeobox-containing gene deficiency disorders (SHOX-Ds) are associated with excess extracellular-signal-regulated kinase (ERK) signalling, similar to achondroplasia. All 3 are characterized by short stature, among other phenotypes. Treatment with human growth hormone (hGH) is standard of care, but response generally declines over time. Vosoritide, an analogue of the master growth regulator C-type natriuretic peptide, is an approved targeted therapy for achondroplasia that stimulates endochondral bone growth by reducing ERK activity. Phase 2 proof-of-concept studies in children with short-stature disorders including Noonan syndrome (NCT04219007) and Turner syndrome (NCT05849389) are ongoing. Study 111-211 (NCT06668805) is a phase 2, randomized, active-controlled, multicentre basket study to generate efficacy and safety data across a range of vosoritide doses vs hGH in children with genetically confirmed Turner syndrome, Noonan syndrome, or SHOX-D with inadequate response to hGH. Participants will be aged ≥ 3 years and < 11 years (females) or < 12 years (males) and prepubertal with height Z-scores ≤ -2.00 from US Centers for Disease Control and Prevention (CDC) average-stature references. Participants must have been receiving ≥ 0.35 mg/kg/week hGH for ≥ 1 year or an optimized dose according to the local standard of care without dose changes in the previous 6 months. They must have an inadequate hGH response that is less than age- and sex-matched average-stature annualized growth velocity (AGV) determined using median heights from CDC growth charts. Baseline AGV will be prospectively established during a 6-month growth assessment phase while participants continue their hGH regimen. Randomization will be 1:1:1:1 to 7.5, 15.0, or 22.5 μg/kg/day vosoritide or daily hGH at a dose equivalent to participants' previous regimen. Study-site personnel and participants will be blinded to vosoritide doses; hGH will be open-label. Transition to the selected therapeutic vosoritide dose will occur after the 6-month dose-finding phase for vosoritide participants and after 24 months for hGH participants, if desired. Treatment will continue until participants are near final adult height (FAH), and follow-up will continue until FAH. The primary objective is to evaluate the efficacy of 3 doses of vosoritide vs hGH as measured by change from baseline (CFB) AGV after 6 months of treatment. Secondary endpoints include CFB height and height Z-score at 6 months; CFB height, height Z-score, and AGV over 24 months (therapeutic dose vs hGH); and adverse event incidence. This study may support vosoritide as a second-line treatment for these conditions if hGH treatment becomes inadequate.

Youn adults with prader willi syndrome - chalenge for endocrinologist, single centre observation

Magdalena Goralska[1], Agnieszka Stańczyk[1] & Urszula Ambroziak[1]
[1]Warsaw Medical University, Endocinology, Warsaw, Poland

Introduction
Prader-Willi syndrome (PWS) is a complex genetic disorder characterized by a set of phenotypic traits, which include infantile hypotonia, short stature, and morbid obesity. Hypothalamic disorders observed in patients with PWS are responsible for a variety of symptoms, including severe hyperphagia and endocrine disorders, such as growth hormone deficiency, hypothyroidism, hypothyroidism, and hypogonadotropic hypogonadism. Growth hormone (GH) deficiency is a common endocrine problem in PWS patients not only in childhood but also in adults. Recombinant human growth hormone (rhGH) therapy and hormonal replacement therapy, serves to achieve an ultimate height and compensate for metabolic abnormalities. Hormonal disorders diagnosed and treated in childhood require continuation and constant monitoring in adulthood. In some patients, hypothyroidism or adrenal insufficiency doesn't appear until adulthood. Patients with PWS require constant multidisciplinary care, including an endocrinologist.
Aim
The aim of the study was to assess the metabolic and hormonal profile of young adults with PWS. Additionally, we compared patients treated with GH since childhood with PWS never treated with growth hormone.
Material and Methods
This study including 52 young adults with PWS, 25 woman and 27 men. The average age of patients is 23 years (man) and 24 years (women). PWS patients were divided into two groups: treated with growth hormone since childhood (37 patients) and not treated with GH (15 patients). Body weight, BMI and percentage of body fat were assessed in all patients. Fasting glucose and insulin levels, lipid profile and hormone levels were assessed and statistically analysed comparing both groups. The GH treatment was monitored with IGF-1 serum levels.
Results
In all patients with PWS (100%) were diagnosed growth hormone deficiency and hypogonadism, requiring substitution treatment. Hypothyroidism was found in 68%, and adrenal axis impairment in 50% patients. The group of GH treated patients, had statistically lower body fat percentage and BMI degree and normal IGF-1 level in comparison to untreated group. HOMA-IR index was statistically lower in the GH-treated group. There were no differences in the incidence of hypothyroidism or adrenal insufficiency in both groups.
Conclusions
The main aim of PWS clinical management in adulthood is prevention of obesity and its comorbidities, treatment of hormonal disorders, mental health stabilization, nutritional guidance, as well as on-going physiotherapy. Integrated multidisciplinary therapeutic interventions, including endocrine ones are necessary if patients with such a complex genetic condition as PWS are to not only achieving average life expectancy, but also to enjoy higher quality of life.

Paediatric langerhans cell histiocytosis disease: long-term sequelae in the hypothalamic endocrine system

Hanan Boualam[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane Elmghari[1] & Nawal Elansari[1]
[1]Mohammed VI University Hospital of Marrakech, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Langerhans cell histiocytosis (LCH) is a disorder of the mononuclear phagocyte system that can affect almost any organ and system. The most common central nervous system (CNS) manifestation in LCH is the infiltration of the hypothalamic-pituitary region leading to destruction and neurodegeneration of CNS tissue, causing the most frequent endocrinological manifestation which is central diabetes insipidus (CDI), and less often anterior pituitary hormone deficiency (APD). Growth hormone is the most commonly affected anterior pituitary hormone.
Case Report
We report the case of an 11-year-old boy who had been treated since the age of 1.5 years for multisystemic Langerhans cell histiocytosis with chemotherapy and who was admitted for short stature. Magnetic resonance imaging showed a moderate reduction in the thickness of the extra-axial mass of the brain scythe, with no detectable abnormalities in the pituitary or pituitary stalk. Endocrinological examinations revealed a profound growth hormone deficiency and partial central hypocorticism. The patient was put on hydrocortisone and growth hormone, with a good progression in height to the mean at the age of 19. The patient did not present with diabetes insipidus nor any other antehypophyseal deficiency.
Discussion/Conclusion
Patients who develop endocrine LCH disorders are at a high risk of neurodegeneration of CNS tissueand require long-term follow-up. Despite significant advances in the knowledge of LCH in recent years, little progress has been made in preventing long-term sequelae such as those affecting the hypothalamic-pituitary system.

Statural advance: a challenge for diagnosis and management

Ghita Khamel[1], Ikram Qasdi[1], Kaoutar Rifai[1], Hind Iraqi[1] & Mohamed Hassan Gharbi[1]
[1]CHU Ibn Sina, Rabat, Morocco

Introduction
Tall stature is defined as a height greater than or equal to +2 standard deviations (SD) on the reference growth curves, or a height greater than 1.5 SD in relation to the genetic target height. While stunted growth is a frequent reason for consultation, overgrowth is often a rarer and more specialized problem. The interest lies in the identification and management of the cause, as well as the indication of a restraining treatment when the psychological repercussions are significant.
Observation
This is a 14-YEAR-OLD patient with no notable pathological history, menarche at the age of 11, who consulted us for tall stature with no similar cases in the family: A height of 174 cm situated between plus 2DS and3DS on the reference curves with a target height of 164 cm, greater than 2DS of the genetic height, the pubertal stage is S4P4, there were no dysmorphic features or signs of associated hyperandrogenism in our patient, the karyotype was normal, the thyroid work-up was normal FSH:3.9UI/L LH:2.8UI/l OESTRADIOL:29.7 pg/ml IGF1: 325 ng/ml z score -0.42. pituitary MRI was without abnormality and bone age was 13 years. a pre-therapeutic blood and morphological workup was requested which was without anomaly.
Discussion
Normal growth requires the integrity of the endocrine and bone systems, regulated by intrinsic (genetic) and extrinsic factors. The causes of early stature are likely to be genetic, endocrine or constitutional. Depending on the presence of body dysmorphia and disproportion, and neurodevelopmental disorders such as sotos, marfan or klinfelter sd (chromosomal anomaly). And for endocrine causes, the existence of hyperthyroidism, an excess of sex hormones as in aromatase deficiency, or GH hypersecretion in somatotropic adenomas. The diagnosis of contitutional tall stature remains a diagnosis of elimination after a rigorous search for other causes with karyotyping. In our patient, no cause was identified, but the indication for treatment was given in view of the psychological impact. Therapeutic options are limited, and only high-dose sexual steroids have benefited from sufficient clinical trials. Treatment is most effective when administered before the bone age of 12 years. In our patient, the choice of treatment was ethynil estradiol 6 mg/day, after elimination of contraindications to this treatment, combined with a progestin for 10 days.
Conclusions
Any child presenting with tall stature should be carefully evaluated to exclude any underlying pathology. Psychological impact remains the main indication before starting treatment.

Clinical and genetic analysis of three cases of short stature caused by the GHSR gene mutation in chinese

xiaoyan wang[1]
[1]Children's Hospital of Soochow University, Suzhou, China

Objective
The aim of this study was to investigate the clinical and genetic characteristics of three cases of short stature caused by the *GHSR* gene mutation.
Methods
A retrospective analysis was conducted on the clinical data and genetic test results of three cases of short stature caused by the *GHSR* gene mutation. The patients were followed up at the Department of Endocrinology Genetics and Metabolism of the Children's Hospital of Soochow University.A literature search (search terms included "*GHSR*" and "short stature") for recently published studies was completed using the China National Knowledge Infrastructure database, WanFang database, PubMed, and the Human Gene Mutation Database.Results: The peak value of growth hormone provocation test in two cases was > 10 ng/ml, and the height of two patients was improved after recombinant human growth hormone therapy. One untreated patient was followed up until lifelong height was reached, and the patient remained with a short stature.
Conclusion
The peak value of growth hormone provocation test in patients with *GHSR* gene variants may be > 10 ng/ml, these patients may have precocious puberty, and short stature caused by the *GHSR* gene mutation can be treated with growth hormone.

Endocrine comorbidities in adult patients with Turner syndrome

Nassim Ben Hadj Slama[1], Imen Halloul[1], Lamys Abbes[1], Ghachem Aycha[1], Ghada Saad[1] & Yosra Hasni[1]
[1]Farhat Hached University Hospital, Endocrinology, Sousse, Tunisia

Background
Turner syndrome (TS) is characterized by a great variability of clinical manifestations caused by a total or partial loss of X-chromosome. Among these manifestations, numerous endocrine disorders have been associated with TS.
Objective
To evaluate the prevalence of endocrine comorbidities developed in adulthood in patients with TS.
Patients and Methods
Prospective longitudinal study including patients with TS aged over 15 years old and followed in the endocrinology department of Farhat Hached university Hospital Sousse.
Results
A total of 33 female patients aged between 15 and 54 years with an average age of 25.6 years were enrolled. Age at diagnosis was 16.3 ± 6.4 years, with 42.2% of cases diagnosed after the age of 18 years old. Chromosomal abnormalities were classified as monosomy X in 54.4%, structural abnormality alone in 18.2% and monosomy with structural abnormality in 27.3%. The most frequent circumstance for discovery was delayed stature and puberty (39.4%). Statural retardation was present in 87.9%, with 9.1% having a severe form. Ovarian insufficiency was found in 87.9% of cases, with delayed puberty in 44.8%. Diabetes was diagnosed in 3 patients, one with type 1 diabetes and two with type 2. The mean BMI was 24.62 kg/m 2, with 18.1% obese. One third of patients developed dysthyroidism, in the form of hypothyroidism in 90% of cases. The mean age of onset was 19 ± 9.32 years, with antithyroid antibodies positive in 90%. Celiac serology was negative in all patients. Hypovitaminosis D was diagnosed in 97%.
Discussion
In addition to ovarian insufficiency, patients with TS may present with several comorbidities, notably endocrine and metabolic, and this is progressive over time, indicating an adapted and prolonged monitoring rhythm to detect these different pathologies in time. This follow-up should ideally be carried out by an endocrinologist.

Somatotroph non functionnal pituitary adenoma: a case report

Fatima Zahra El Jaafari[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakech, Marrakech, Morocco

Introduction
Clinically nonfunctioning pituitary adenomas (NFPAs) include all pituitary adenomas that are not hormonally active. They account for 15-30% of pituitary adenomas, and are usually diagnosed by signs and symptoms related to a mass effect (headache, visual impairment, sometimes pituitary apoplexy), but also incidentally. In histopathology, somatotroph nonfunctional pituitary adenomas are considered rare, the majority of NFPAs are gonadotroph. They are associated to increased comorbidities, and reduced long-term survival.
Material and Methods
We report the case of a patient presenting NFPA which expressing anti-GH antibody. He is followed up in the Endocrinology, Diabetology and Metabolic diseases department of the Mohamed VI university hospital center in Marrakech.
Case presentation
A 56-year-old man, presented a tumoral syndrome made of decrease of visual acuity, and retroorbital headache. He had no particular medical history. He reported a decrease of the libido and erectile dysfunction evolving over the past 6 months. Laboratory workup revealed a normal insulin-like growth factor I (IGF1), 8 a.m. cortisol level, Thyroid-stimulating hormone (TSH) and prolactin, a gonadotropic deficiency FSH: 2,1 UI/l, LH: 0,6 UI/l Testosterone: 0.5. Pituitary MRI showed intra- and supra-sellar tumor process compressing the optic chiasm, suggesting in the first instance a pituitary adenoma measuring 45 x 33 mm. The ophthalmologic examination showed bilateral blindness. A transsphenoidal adenomectomy was performed in the neurosurgical department, and the anatomopathological and immunohistochemical study revealed a non-secreting pituitary adenoma expressing the anti-GH antibody. During follow up, biological tests showed in addition to the known gonadotropic deficiency, corticotropic and thyreotropic deficiencies were also

present, which we substituted. The MRI imaging showed persistence of the sellar lesion process measuring 12 x 22 x 19 mm. Blindness persisted even after surgery. Radiotherapy treatment was indicated, but the patient refused it.
Conclusion
Somatotroph adenomas are usually accompanied by symptoms of acromegaly and an elevated plasma growth hormone (GH) and IGF-1 level. GH-immunopositivity occurs in a rare case of all tumor types of clinically non-functioning adenomas. Because of that, the diagnosis should be done by immunohistochemical techniques, which may provide information on tumor cell proliferation and biologic behavior.
Keywords
Non-functional pituitary adenomas, Gonadotroph adenoma, MRI, Adenomectomy, immunohistochemical techniques.

A new prospective for the growth suppression in children with profound mental disability; case report and ethical consideration

Ahlam Alotaibi[1], Heba Ghandora[2] & Halimah Alsomali[3]
[1]Division of Pediatric Endocrinology, Department of pediatric, College of Medicine, King Saud University, Riyadh, Saudi Arabia, The University Diabetes Centre, King Saud University Medical City, King Saud University., Riyadh, Saudi Arabia; [2]Division of Pediatric Endocrinology, Department of Pediatric, College of medicine, King Saud bin Abdulaziz University for Health Science, KAMC, Jeddah, Saudi Arabia; [3]Department of Pediatric, KAAUH, Riyadh, Saudi Arabia

Introduction
- In children with profound mental disability, the normal linear growth and pubertal maturation can affect their life and their caregivers' life in a negative way especially with limited mobilization and increased body size.
- The three most prevalent disabilities in Saudi Arabia are: motor disability at a rate of (1.0%), followed by visual impairment and communication disability at a rate of 0.6% each.
- There is limited data on the use of high dose estrogen dose to close the growth plates earlier and cause growth suppression.

Case
- 10 years old boy, diagnosed with Spastic paraplegia type 86 based on genetic test. Which is an autosomal recessive complex neurological disorder, expressed by early childhood developmental delay, progressive spasticity that mainly affect the lower limbs, with inability to walk and cause intellectual developmental impairment.
- Currently; he speaks 10 to 15 words, can sit, crawl and stand, but cannot walk. He was referred to endocrine service with growth failure, went under growth hormone stimulation test, which was indicate growth hormone deficiency based on peak of GH 0.9.
- We counseled the family to start a high dose of growth hormone for growth and metabolic effect or use a low dose of growth hormone for metabolic impact only, and they elected to choose the high dose GH therapy.

Discussion
- Growth suppression in children with profound cognitive and physical disabilities consider ethically questionable. It can be viewed from several perspectives:

1- Construct Argument:
- **Beneficences:**
- **Direct benefit to the patients and their families** by improving quality of life (mobilization, decreasing bed sores, and risk of obesity).
- **-Indirect benefit to the society**
- **Justice:**

-No research in this field is Not harmful but avert benefice.
-No research in this field Augment vulnerability.

2- Counter Argument:
- **Consent and conflict of interest**

Estrogen therapy for growth suppression is a research medication and consent by third party (not by family) is indicated.
- **Harm.**
- **Social Injustice.**

Conclusion
- Growth attenuation offers the possibility of an improved quality of life for children with profound cognitive disability.
- It can be achieved naturally by allowing precocious puberty to run its course or by treating GH deficiency with metabolic dose (Passive suppression).
- Estrogen therapy is ethically questionable

Glucose metabolism disorders in patients with acromegaly

Yesmine Elloumi[1], Wissal Abbes[1], Dhoha Ben Salah[1], Khouloud Boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Glucose metabolism disorders are common complications of acromegaly, contributing significantly to morbidity in affected patients. Understanding the factors associated with these disorders is essential to optimize their management. This study aims to investigate the frequency and the characteristics of glucose metabolism disorders in patients with acromegaly.
Methods
This was a retrospective study involving 32 patients with acromegaly treated at the Endocrinology Department of Hedi Chaker University Hospital, Sfax, over a 16-year period. The patients were divided into two groups: Group 1, consisting of 24 patients with glucose metabolism disorders, and Group 2, consisting of 8 patients without such disorders.
Results
la fréquence du trouble du métabolisme glucidique était de 75%. Diabetes Mellitus was identified in 17 patients (71%), while glucose intolerance was noted in 7 cases (29%). Glucose metabolism disorders were diagnosed, on average, 7.5 years after the onset of acromegaly. Treatment consisted of dietary measures alone in 11 cases (45%), oral antidiabetics in 7 cases (29%), insulin alone in 3 cases (12.5%), and a combination of insulin and oral antidiabetics in 3 cases. The underlying cause of acromegaly was a Somatotroph macroadenoma in 14 patients, microadénoma in 7 patients, and ectopic secretion of growth hormone-releasing hormone in 1 patient. Among 20 patients who received treatment for acromegaly, 5 showed improvement in glucose metabolism. After successful treatment of acromegaly, the overall improvement rate in glucose metabolism was 21%.
Conclusion
Acromegaly is a multifaceted disease that requires careful evaluation and management. Advancing our understanding of its metabolic impact is crucial for optimizing care strategies.

Pituitary acrogigantism from diagnosis to effective treatment- case study

Magdalena Goralska[1], Gabriela Budziszewska[2] & Urszula Ambroziak[1]
[1]Warsaw Medical University, Endocinology, Warsaw, Poland; [2]Warsaw Medical University, Warsaw, Poland

Introduction
Pituitary acrogigantism is a very rare endocrine disease that is caused by chronic growth hormone (GH) and its mediator, insulin-like growth factor 1 (IGF-1) axis excess, that begins during childhood and adolescence. As such, it represents one of the most severe manifestations of acromegaly. In most cases, acrogigantism is caused by a pituitary adenoma. The disease leads to numerous complications, including metabolic, cardiovascular, and oncological issues. Despite advances in diagnosis and treatment, delays in recognition remain a challenge. Treatment of pituitary acrogigantism involves a multimodal approach, combining surgical, pharmacological, and in some cases radiotherapy interventions. The use of somatostatin analogues first and second generation has significant role, especially in patients with incomplete tumor resection or persistently high levels of GH and IGF-1.
Case study
The study is based on the case analysis of a 21-year-old patient, diagnosed with pituitary acrogigantism due to a pituitary macroadenoma. A pituitary tumor was revealed during the diagnosis of chronic otitis. Diagnostics included laboratory tests (levels of GH in OGTT *oral glucose tolerance test,* IGF-1) and imaging studies (pituitary MRI, thyroid and abdominal ultrasound, echocardiography). Treatment involved surgical intervention (endoscopic tumor resection), pharmacological therapy (lanreotide) and monitoring of therapy progress. After tumor resection, partial normalization of GH and IGF-1 levels was achieved; however, symptoms of active acromegaly persisted. Lanreotide treatment was initiated, leading to further improvement in hormonal parameters and the patient's well-being. Nevertheless, in the following months, recurring symptoms such as chronic fatigue, excessive sweating, and joint pain were observed. A second generation

analogue -pasireotide were used, resulting in normalization of IGF1 and good disease control. Actually patient is a is a first-year medical student.
Conclusions
Patients with pituitary acrogigantism have a heavy burden of disease and a complex treatment journey. Rapid implementation of surgical and pharmacological treatment is crucial. The use of somatostatin analogues is effective in controlling GH and IGF-1 levels in patients with residual disease activity. A second generation somatostatin analogues are perspectives for patients with hard-to-control acromegaly.

Two-year-old dizygotic twins diagnosed with rabson-mendenhall syndrome

Violet Swain[1], Zoe Tattersall[1], Helen Day[1] & May Ng[1]
[1]Ormskirk District General Hospital, Diabetes Team, Ormskirk, United Kingdom

Rabson-Mendenhall Syndrome (RMS) is a rare, autosomal recessive disorder caused by mutations in the *INSR* gene, leading to severe insulin resistance, dysmorphism and multisystemic complications. The features of RMS overlap with other metabolic and genetic disorders which can lead to delayed diagnosis. To our understanding, the twins presented in this case report are the youngest diagnoses of RMS globally. Lilac was brought to the attention of the general paediatricians with dysmorphic features, failure to thrive, developmental delay and significant polyuria and polydipsia. As her twin, Marigold, was found to have similar features, she was also investigated. A high HbA1c resulted in a referral to the diabetes team who put together the clinical features of dysmorphism, acanthosis nigricans and insulin resistance for a suspicion of Rabson-Mendenhall Syndrome; this was confirmed some months later for both fraternal twins by genetic testing. Following a difficult discussion explaining the diagnosis to parents, a multidisciplinary approach was taken that initially focused on continuous blood glucose monitoring to detect early morning hypoglycaemia and nutritional support. Metformin was started at 100 mg once-daily and then Increlex (Mecasermin) injections were started at 0.04 mg/kg once-daily under inpatient observation, titrated to 0.04 mg/kg twice-daily after six weeks. General monitoring for growth and development is ongoing. The early stage of RMS poses significant metabolic challenges due to early morning hypoglycaemia and postprandial hyperglycaemia and thus nutritional interventions are invaluable at this time. Early recognition and management of Rabson-Mendenhall Syndrome is extremely preferable over a presentation in treatment-resistant diabetic ketoacidosis which is often the case. Prompt diagnosis and use of targeted therapies can be essential in mitigating severe complications. Given the young age at diagnosis and the rarity of RMS, this case is being managed in collaboration with national experts however there is little evidence base for the treatments being offered. We hope this report will highlight the need for further research into novel therapeutic options and long-term management strategies for this challenging condition.

CiR-EIS sponges miR-548 to ameliorate metabolic dysfunction-associated steatohepatitis via regulating macrophage polarization

Zhiping Wan[1], Xiaoman Chen[1], Xiang Cai[1], Hang Si[1], Xiaoquan Liu[1] & Hong Deng[1]
[1]Third Affiliated Hospital of Sun Yat-sen University, Guangdong Provincial Key Laboratory of Liver Disease Research, Department of Infectious Diseases, Guangzhou, China

Introduction
Metabolic dysfunction-associated steatohepatitis (MASH) is a significant public health concern, with macrophage phenotypes implicated in its progression. Although Extensive Inflammation-Suppressing Circular RNA (CiR-EIS) has been implicated in inflammation regulation, its role in macrophage polarization within the context of MASH remains unexplored. This study aimed to clarify the effect of CiR-EIS on macrophage polarization in MASH.
Methods
Immunofluorescence-fluorescence *in situ* hybridization was used to evaluate the localization of CiR-EIS in human liver sections. Real-time quantitative polymerase chain reaction (RT-qPCR) was used to detect the expression of CiR-EIS in serum and cells. Flow cytometry was employed to evaluate macrophage polarization. Enzyme linked immunosorbent assay (ELISA) was used to detect the content of inflammatory factors. Dual luciferase reporter assay was used to identify the downstream targets of CiR-EIS.
Results
CiR-EIS was downregulated in patients with MASH and localized in liver macrophages. Compared with the control group, the expression of CiR-EIS in M1 macrophages was decreased. Overexpression of CiR-EIS significantly inhibited M1 macrophage markers CD86, interleukin-1 beta (IL-1β), and tumor necrosis factor-alpha (TNF-α) while enhancing M2 macrophage markers CD163 and CD206. MiR-548 was screened and identified as a downstream target of CiR-EIS. Up-regulation of miR-548 promoted M1 macrophage polarization and reduced M2 macrophage polarization. CiR-EIS had a region that binds to miR-548. CiR-EIS sponged miR-548 to regulate the polarization of macrophages. In addition, the serum CiR-EIS content of MASH patients was lower than that of healthy people. The content of CiR-EIS in serum was negatively correlated with the content of alanine aminotransferase (ALT) and aspartate aminotransferase (AST).
Conclusions
CiR-EIS regulates macrophage polarization by sponging miR-548, thereby ameliorating MASH. It demonstrates potential as a diagnostic marker and therapeutic target for MASH.

Clinical and therapeutic characterization of patients with familial hypercholesterolemia: multicenter cross-sectional study

Ana Garcia-Zarzuela[1], Jesus Domnguez-Riscart[1], Maria Angeles Santos-Matos[2], Nuria Buero-Fernandez[3], Jessica Guarino-Naravaez[4] & Nereyda Rojas-De Gonzalez[5]
[1]Hospital Universitario Puerta del Mar, Cadiz, Spain; [2]Hospital Universitario Jerez, Jerez, Spain; [3]Hospital Universitario Puerto Real, Puerto Real, Spain; [4]Hospital Universitario Punta de Europa, Algeciras, Spain; [5]Hospital Nuevo La Linea, La Linea de la concepción., Spain

Familial hypercholesterolemia (FCH) is a hereditary disease that presents with elevated LDL, xanthomas and early coronary heart disease. Genetic tests are not essential for the diagnosis of FH but are useful to assess cardiovascular risk and response to treatment regardless of LDL levels. Our main objective is to describe the genetic findings in the patients studied and describe the clinical, analytical and treatment characteristics in people with hypercholesterolemia with a genetic study performed, as well as the comparison of the same among those in which genetic variants of HCF are detected. and not those who don't.
Material and Methods
Observational, cross-sectional and analytical study in which all patients with hypercholesterolemia in whom a genetic study of HCF has been performed in 5 hospital centers in the province are collected. For genetic diagnosis, next-generation sequencing (NGS) techniques were used, which include the genes LDLR, APOB, PCSK9, APOE, LDLRAP1 and LIPA. Clinical, analytical and therapeutic data were collected from the patients. Statistical inference is performed using Student's t-test for comparison of means and Chi-square for comparison of proportions between groups. A statistically significant difference is considered with a p-value less than 0.05.
Results
117 patients were included, with a mean age of 11.66 +/-3.64 years and a mean BMI of 19.14 +/-4.91. The most reported gene was LDLR (53 patients; 76.8%) followed by APOB (9 patients; 13%). The average total cholesterol is 259.61 60.82 mg/dl with an average LDL cholesterol of 186.68 64.52 mg/dl. In the group of patients with positive genetics, the mean LDL cholesterol is 210.87 66.94 mg/dl while in the control group it is 151.17 40.21 mg/dl ($p < 0.01$). Of the total sample, 71 (60.7%) received lipid-lowering treatment, being more frequent in patients with positive genetics (71% vs. 45.9%) ($P = 0.02$), in addition, 12 patients had a combination of > 2 drugs (16.9%), all of them belonging to the group with positive genetics. The most commonly used drugs are atorvastatin and rosuvastatin. No statistically significant differences were observed in LDL levels after starting treatment in both groups, although the mean reduction in LDL levels was greater in the group with positive genetics (99.15 78.92 mg/dl vs. 50. 05 40.25 mg/dl).
Conclusions
- Total and LDL cholesterol levels were higher in the group with positive genetics findings.
- In patients with positive genetics we observed a greater proportion of lipid-lowering treatment as well as a greater combination of them.

Time-restricted feeding in children and adolescents with obesity (the transform study): a randomized controlled trial evaluating anthropometric, metabolic, and gut microbiome outcomes

Paula Molina Giraldo[1], Laura Meis[1], Serafin Murillo Garcia[1], Josep Jimenez Chillarón[1], Lourdes Ibañez[1], Marta Ramon Krauel[1] & Carles Larin Martinez[1]
[1]Hospital Sant Joan de Deu, Barcelona, Spain

Introduction
Time-restricted feeding (TRF) has demonstrated metabolic improvements in adults with obesity, although evidence in pediatric populations is limited. The TRansForm study (*ClinicalTrials.gov* ID: NCT05174871) evaluated the safety and effectiveness of a 2-month TRF intervention in children and adolescents with obesity, focusing on anthropometric, metabolic, and gut microbiome outcomes.
Design
This open-label, parallel-group randomized controlled trial allocated (1:1) participants (ages 8–18, BMI-SDS > 2) stratified by gender and age into TRF (late 8-hour feeding window, 6 days/week, plus usual care) or Control groups (usual care only). Primary outcomes included safety and BMI-SDS changes at 2 and 12 months. Secondary outcomes encompassed metabolic parameters and gut microbiome. Analysis was conducted using multiple linear regression, adjusted for sex and pubertal status.
Results
Sixty-five participants completed the intervention, and 53 attended the 12-month follow-up. Baseline characteristics included 54% female, average age 13.8 ± 2.5, 18% prepubertal, and BMI-SDS 3.06 ± 0.64. No major adverse events were documented. Median self-reported adherence was 5 ± 3 days/week, with 50% attaining adherence > 80% (≥ 5 fasting days/week). Males and prepubertal individuals exhibited higher probabilities of high adherence than females and postpubertal (X^2 P = 0.029 and P = 0.040, respectively). TRF (n = 32) and Control (n = 33) groups showed similar BMI-SDS improvements at 2 (−0.09 ± 0.16vs−0.07 ± 0.12, respectively) and 12 months (−0.11 ± 0.41vs−0.09 ± 0.38). Regression models with high-adherence participants revealed significant BMI-SDS improvements following TRF compared to controls (−0.24 ± 0.11vs.−0.07 ± 0.12) (Table 1). TRF increased LDL-cholesterol levels at 2 and 12 months while marginally reducing HDL-cholesterol (Table 1). No differences were observed in physical activity or energy intake. Microbiome analysis from TRF participants revealed decreased α-diversity (P < 0.05), lower fecal short-chain fatty acids, and increases in potentially pathogenic bacteria, including *Yersinia*, *Escherichia coli*, and *Salmonella enterica* strains.
Conclusions
While TRF may improve BMI-SDS, its potential association with worsening lipid profiles and gut dysbiosis raises safety concerns. These findings highlight the necessity for personalized TRF protocols and rigorous metabolic monitoring for pediatric obesity. Further research is required to determine the long-term impact of TRF on pediatric health, as well as the mechanisms linking feeding windows to microbiome-host interactions.

Evolution after bariatric surgery in patients with genetic mutations related to monogenic obesity

Cristian Jesús Lucena Morales[1], Andrés López Rodríguez[2], Laura Larrán Escandon[1], Isabel María Mateo Gavira[1] & Jesús Dominguez Riscart[3]
[1]Hospital Universitario Puerta del Mar, Endocrinology and Nutrition Department, Cádiz, Spain; [2]Faculty of Medicine, University of Cádiz, Cadiz, Spain; [3]Hospital Universitario Puerta del Mar, Pediatrics and Specific Areas Department, Cadiz, Spain

Study Objectives
Monogenic obesity, linked to more than 130 identified genes, is often characterized by hyperphagia and early-onset obesity. This study aims to analyze changes in anthropometric and clinical parameters in a cohort of patients with genetically confirmed obesity-related mutations, one year after undergoing bariatric surgery.
MaterialS And Methods
A descriptive, cross-sectional study was conducted on a cohort of subjects with grade 3 or higher obesity and positive genetic findings, managed at the Bariatric Surgery Clinic (Endocrinology) of Puerta del Mar Hospital. An obesity gene panel was used, based on whole-exome sequencing of 80 genes, including copy number variation analysis.
Results
The study included 52 patients meeting the specified criteria. Of these, 79.6% were female. The median age at the time of surgery was 49.46 years. The median age of obesity onset was 11.5 years (range 6–23.5), and 71.1% had a family history of obesity. The majority of patients (75%) underwent vertical sleeve gastrectomy, while the remaining 25% had a gastric bypass. Preoperative weight was 109.52 ± 16.56 kg (BMI 41.19 ± 4.95 kg/m^2), and postoperative weight at one year was 81.05 ± 13.45 kg (BMI 30.49 ± 4.47 kg/m^2). The percentage of excess weight lost was 58.47 ± 20.06%, the percentage of total weight lost was 25.79 ± 8.16%, and the percentage of excess BMI lost was 69.39 ± 26.16%. Regarding the HQ-CT questionnaire validated for hyperphagia, the median score was 13 (9.75–16). The mean score on the BAROS scale (quality of life) was 5 ± 2.52, with 27.8% achieving excellent outcomes, 27.8% very good, 27.8% good, 5.6% fair, and 11.1% classified as treatment failures.
ConclusionS
Our cohort demonstrates that bariatric surgery can be an effective tool for weight loss, at least in the short term, in individuals with grade 3 obesity and genetic alterations associated with obesity. It would be of interest to compare these results with patients with negative genetic findings and those undergoing medical treatment targeting specific pathways related to MC4R (e.g., setmelanotide).

Higher daytime systolic blood pressure, prepregnancy body mass index and an elevated sFlt-1/PlGF ratio predict the development of hypertension in normotensive pregnant women

Almudena Lara-Barea[1], Begoña Sánchez-Lechuga[1], Manuel Aguilar-Diosdado[1] & Cristina López-Tinoco[1]
[1]Puerta del Mar Hospital, Endocrinology and Nutrition Department, Cádiz, Spain

Background
The risk of hypertensive disorders of pregnancy (HDP) varies in women with gestational diabetes mellitus (GDM), depending on the degree of insulin resistance and is also influenced by obesity. The aim of this study was to evaluate clinical features, blood pressure (BP) profiles and inflammatory markers, to identify patients with an elevated risk of developing HDP.
Methods
A total of 146 normotensive pregnant women were studied. We analysed the relationships of BP profiles detected by ambulatory blood pressure monitoring (ABPM) with serum biomarkers and angiogenic factors and their association with the development of HDP.
Results
Fourteen (9.6%) women developed HDP. The table shows the association between the development of HDP, biomarkers' levels and ABPM parameters.

Table 1. Pearson correlation coefficients between hip geometry variables and fat mass at different sites

Variable	HDP (n = 14)	Non-HDP (n = 132)	p Value
Cytokines and biomarkers levels *			
Adiponectin, (pg/ml)	10.22 ± 2.54	13.08 ± 2.93	0.06
Resistin (pg/ml)	7.43 ± 3.82	8.28 ± 3.28	0.37
PAI-1 (pg/ml)	8.04 ± 4.08	8.69 ± 3.48	0.51
Leptin (pg/ml)	10.97 ± 0.82	10.2 ± 1.11	**0.018**
HGF (pg/ml)	6.65 ± 1.07	7.03 ± 1.23	0.41
MCP-1 (pg/ml)	5.24 ± 0.60	4.9 ± 0.55	**0.044**
TNFα (pg/ml)	0.35 ± 2.02	0.59 ± 1.13	0.49
sFlt-1 (pg/ml)	7.56 ± 0.93	7.25 ± 0.97	0.26
PlGF (pg/ml)	3.18 ± 1.79	5.1 ± 1.12	**0.002**
sFlt-1/PlGF ratio	4.37 ± 2.2	2.2 ± 1.43	**0.003**
BP parameters			
24h SBP (mmHg) *	113.1 ± 14.4	104.2 ± 7.9	**0.04**
24h DBP (mmHg) *	69.7 ± 9.2	64.1 ± 5.6	**0.04**
Daytime SBP (mmHg) *	115.7 ± 13.4	106.7 ± 8.6	**0.001**
Daytime DBP (mmHg) *	72.3 ± 8.2	66.6 ± 6.0	**0.002**
Nocturnal SBP (mmHg) *	107.5 ± 17.5	98.7 ± 7.8	0.08
Nocturnal DBP (mmHg) *	63.5 ± 12.1	58.5 ± 5.6	0.15
Pathological circadian pattern †	9 (64.3%)	62 (46.9%)	0.17

Multivariate analysis showed that a higher sFlt-1/PlGF ratio was associated with an increased risk of developing HDP [Or=2.02; IC 95%: 1.35–3.05]. Furthermore, higher daytime systolic BP [Or=1.27; IC 95% 1.00–1.26] and prepregnancy body mass index (BMI) [Or=1.14; IC 95%: 1.01–1.30] significantly increased the risk of developing HDP.
Conclusions
Higher daytime systolic BP values, prepregnancy BMI and the sFlt-1/PlGF ratio are useful for identifying normotensive pregnant women with an increased risk of developing HDP.

SGLT-2 inhibitors do not decrease tsh levels despite weight reduction, unlike GLP-1 agonists

Mikulas Kosak[1], Tomas Burger[1], Ivan Kuzko[1], Monika Nyvltova[1], Johana Venerova[1], Tomas Pelcl[1], Jan Palecek[1], Lucie Pagova[1] & Denisa Janickova Zdarska[1]
[1]Military University Hospital Prague, 1st Faculty of Medicine, Charles University, Department of Medicine, Prague, Czech Republic

Introduction
TSH (Thyroid Stimulating Hormone) elevation in obesity is a recognized phenomenon. While various mechanisms have been proposed, a clear pathogenic mechanism remains undefined. Weight reduction is typically accompanied by a decrease in TSH levels, particularly with GLP-1 receptor agonist treatment. This study aimed to compare the effects of SGLT-2 inhibitors and GLP-1 receptor agonists on TSH levels in relation to weight reduction in patients with type 2 diabetes mellitus (T2DM).
Patients and Methods
This retrospective analysis included T2DM patients who started treatment either with SGLT-2 inhibitors or GLP-1 receptor agonists at our centre. Biochemical and anthropometric data were collected before treatment and after 12 months of therapy. The aim was to compare the effects of both drug classes on body weight, HbA_{1c}, and TSH levels.
Results
Data from 90 patients treated with SGLT-2 inhibitors and 38 treated with GLP-1 receptor agonists were analysed. In the SGLT-2 group, 66 were men and 24 were women, with a mean age of 65.7 years (range 34–88). In the GLP-1 group, 27 were men and 11 were women, with a mean age of 61 years (range 36–74). In the SGLT-2 group, mean BMI decreased from 34.57 $\pm$ 3.6 to 32.8 $\pm$ 3.55 ($p < 0.001$) after 12 months. HbA_{1c} decreased from 65.49 $\pm$ 8.15 mmol/mol to 55.91 $\pm$ 6.73 mmol/mol ($p < 0.001$). TSH levels decreased from 2.16 $\pm$ 0.82 mIU/L to 1.96 $\pm$ 0.6 mIU/L, but the change was not statistically significant ($P = 0.0968$). In the GLP-1 group, mean BMI decreased from 32.93 $\pm$ 4.80 to 30.48 $\pm$ 5.36 ($p < 0.001$). HbA_{1c} decreased from 59.44 $\pm$ 10.25 mmol/mol to 47.69 $\pm$ 7.80 mmol/mol ($p < 0.001$). TSH levels decreased from 3.42 mIU/L to 2.25 mIU/L ($p < 0.001$).
Conclusion
Both GLP-1 receptor agonists and SGLT-2 inhibitors led to significant reductions in BMI and HbA_{1c}. However, a significant decrease in TSH levels was observed only with GLP-1 treatment, suggesting that its impact on metabolism may be broader and more complex, potentially involving mechanisms beyond weight reduction alone.

Gut microbiota and cytokine in children with nonalcoholic fatty liver disease

Xin Yuan[1] & Ruimin Chen[1]
[1]Fuzhou First General Hospital Affiliated with Fujian Medical University, Fuzhou Children's Hospital of Fujian Medical University, Fuzhou, China

Objective
Nonalcoholic fatty liver disease (NAFLD) is one of the most common causes of chronic liver disease in children worldwide. The gut microbiota plays a critical role in human metabolism, and has been appointed as driver of meta-inflammation observed in lipid metabolism and NAFLD, which has not been fully studied in children with obesity.
Methods
Clinical data were collected between June, 2019 and December, 2019 at the Fuzhou Children's Hospital of Fujian Medical University, in China. Data of 89 participants aged between 5 and 15 were examined. Subjects with any endocrine disorder, history of antibiotic therapy, hospitalization (>24 h) in the past 6 months prior to the enrollment, chronic gastrointestinal illness or use of gastro-intestinal-related medication, or diarrheal disease (World Health Organization definition) in the past one month were excluded. Participants with body fat (BF)% $\geq$ 30% were diagnosed as obesity. Serum adropin and leptin levels were measured by ELISA, and the composition of gut microbiota was investigated by 16S rRNA-based metagenomics.
Results
The mean age of the 89 participants were 9.75 $\pm$1.92 years old. Based on BF%, the study population were divided as normal weight ($n = 29$), obesity without NAFLD ($n = 39$) and obesity with NAFLD ($n = 21$) groups. Alpha-diversity such as Shannon index, Observed index and ACE were significantly lower in NAFLD group compared with the Obesity and the Con groups ($P < 0.05$). PCoA analysis revealed that gut microbiota of the NAFLD group were clustered together and separated partly from the Obesity and the Con groups ($P < 0.05$). Compared to the Obesity and the Con groups, subjects with NAFLD had significantly lower prevalent members of phylum Bacteroidetes, genus Alistipes, Anaerotruncus, Bacteroides, Holdemania, Lactonifactor, Oscillospira, Sutterella, and more members of genus Aggregatibacter, Catenibacterium, Morganella, Paraprevotella (all $P < 0.05$). Spearman's correlation analysis revealed that leptin negatively correlated with phylum Bacteroidetes, genus Alistipes, Bacteroides, Holdemania and Lactonifactor. Adropin positively correlated with phylum Bacteroidetes, genus Alistipes, Anaerotruncus, Bacteroides, Lactonifactor, Oscillospira.
Conclusions
The composition of the gut microbiota in children with NAFLD differs from Con. Alterations in the microbiota that produce short-chain fatty acids may contribute to the development of NAFLD by affecting levels of cytokine.

Streamline - machine learning guided development of novel GLP-1 receptor agonists with improved drug properties

Randi Mikkelsen[1], Nina Buch-Månson[1], Claudia Hjørringgaard[1], Jens Christian Nielsen[1], Mads Nygaard[1], Lisbeth Elster[1], Silas Rasmussen[1], Kristoffer Rigbolt[1], Niels Vrang[1] & Louise Dalbøge[1]
[1]Gubra, Hørsholm, Denmark

We have developed streaMLine, an innovative platform for peptide drug discovery that greatly shortens the time from initial hit to clinical drug candidate. The platform allows for high throughput synthesis and screening. Thousands of peptides are systematically screened in *in vitro* assays and on chemical and physical parameters, whereby the streaMLine platform enables complete sequence exploration and simultaneous optimization of key parameters. Using the streaMLine platform, we developed novel GLP-1R agonists from a secretin peptide backbone, to demonstrate how high throughput screening of peptide libraries and machine learning guided drug design can be applied to accelerate drug discovery. We systematically synthesized and screened a total of 2,688 peptides in a parallelized optimization workflow. Using this approach, we were able to generate potent, selective, and long-acting GLP-1R agonists with improved physicochemical properties. To validate the developed QSAR pipeline, we conducted an in-depth profiling of a developed GLP-1R agonist, GUB021794. GUB021794 was tested for cross-reactivity towards other receptors in the glucagon superfamily of receptors and showed no activation of the GIPR, GLP-2R or GCGR when tested at concentrations up to 3000 nM. With a GLP-1R potency of 0.018 nM and a SCTR potency of 190 nM, GUB021794 thus showed high receptor selectivity for GLP-1R. In addition, GUB021794 (S.C., 10 nmol/kg QD) showed potent body weight loss in diet-induced obese (DIO) mice and a half-life in rats compatible with once-weekly dosing in humans. Overall, the preclinical data demonstrate that GUB021794 is a potent, long-acting GLP-1R agonist promoting robust body weight loss in DIO mice comparable to clinically approved GLP-1R agonists such as semaglutide.

High prevalence of MASLD already in children aged below 10 years

Daniela Stanikova[1,2], Lea Krajcovicova[1], Eva Vitariusova[1] & Juraj Stanik[1,2]
[1]Medical Faculty of the Comenius University, National Institute of Childreńs Diseases, Department of Pediatrics, Bratislava, Slovakia; [2]Institute of Experimental Endocrinology, Biomedical Research Center, Slovak Academy of Sciences, Department of Metabolic Disorders, Bratislava, Slovakia

Introduction
Metabolic dysfunction-associated steatotic liver disease (MASLD), formerly known as non-alcoholic steatotic liver disease (NAFLD), is currently the most common liver disease in children due to the increasing prevalence of obesity. MASLD occurs with (mainly) visceral type obesity, dyslipidaemia and/or insulin resistance. The aim of this study was to determine the prevalence of MASLD in obese children.
Methods and patients
Obese patients aged 2.5 to 18.9 years examined at the Endocrinology and Gastroenterology outpatient clinics of the Children's Clinic of the LFUK and NÚDCH in 2018-2023 were included in the study.
Results
In a cohort of 383 obese children and adolescents (179 girls, 204 boys), with a mean age of 13.3 ± 3.4 years and BMI-SDS of 15.4 ± 2.6, MASLD occurred in 222 children (58%). The prevalence of MASLD was not significantly different in children under 10 years (52.2%) and over 10 years (59.2%) ($P = 0.341$). MASLD patients had significantly higher BMI-SDS (5.8 ± 2.6 vs. 4.8 ± 2.5, $P < 0.001$), higher AST, ALT and GMT ($P < 0.001$), as well as HOMA index ($P = 0.002$) and higher liver steatosis and fibrosis index (PNFI), liver function index (FLI) ($P = 0.039$) and liver fibrosis index (HSI) scores ($P < 0.001$ and $P = 0.039$, respectively).
Conclusion
More than half of obese children already have steatotic liver disease associated with metabolic dysfunction, with an alarmingly high prevalence even in children under 10 years of age. *Grant support: APVV-22-0310 and VEGA 2/0128/23*

Predictive factors of fat-free mass loss in obese patients after weight loss interventions

Sana Khamassi[1], Fatma Boukhayatia[1], Haifa Abdesselem[1], Emna Bornaz[1], Kamilia Ounaissa[1], Sana Hammami[2], Houda Bouhajja[3], Amel Gammoudi[4], Awatef Kacem[4], Emna Talbi[3], Jamoussi Henda[4] & Chiraz Amrouche[1]
[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology, Clinical Biology Laboratory, Tunis, Tunisia; [3]National Institute of Nutrition and Food Technology, UR17SP01-Clinical Biology Laboratory, Tunis, Tunisia; [4]National Institute of Nutrition and Food Technology, Obesity Reserach Unit, Tunis, Tunisia

Background
Muscle loss, particularly in the context of obesity, is a significant concern due to its association with various health complications, including insulin resistance, impaired mobility, and an increased risk of chronic diseases [1]. The aim of our study was to evaluate fat free mass loss in obese patients after weight loss intervention and to identify its predictive factors.
Methods
We conducted a prospective study of 100 obese adult patients over 6 months. Body composition was analyzed at baseline and at 6-month follow-up. Gait speed over 4 meters assessed physical performance. Sarcopenic obesity (SO) was defined in accordance with the 2022 EASO-ESPEN consensus statement. A balanced hypocaloric diet was prescribed and patients received regular follow-ups. A significant loss of fat-free mass (FFM) was defined as a reduction of more than 5% in FFM.
Results
The mean age was 44.42 ± 13.25 years and the sex ratio (M/F) was 0.11. At baseline, the mean BMI was 40.07 ± 5.77 kg/m^2. About 20% of the participants had a below-average fat-free mass index of 20.34 ± 2.53 kg/m^2, and 19% were identified as having SO. At 6 months, 78 patients completed the study. The average weight loss and the average FFM loss were 4.13 ± 6.98% and 0.42 ± 5.63%, respectively. Significant loss of FFM was identified in 11% of patients after weight loss intervention. The level of physical activity was comparable between patients with significant FFM loss and those without ($P = 0.42$). Significant FFM loss was associated with a higher prevalence of binge eating disorder (62.5% vs 18.5%;$P = 0.014$) and prediabetes (75% vs 36.9%;$P = 0.039$) at baseline. However, sarcopenic obesity and functional impairment were not significantly associated with FFM loss ($P = 0.14$ and $P = 1.0$, respectively). Dietary survey revealed that significant loss of FFM was associated deficiency in vitamin B9 intake (87.5% vs 36.9%;$P = 0.009$), and deficiency in vitamin C intake (87.5% vs 27.5%;$P = 0.002$) at baseline. However, total caloric intake as well as protein intake were comparable ($P = 0.15$ and $P = 0.07$, respectively). Furthermore, FFM loss was negatively correlated with vitamin B6 intake (r = -0.24;$P = 0.04$) and vitamin B9 intake (r = -0.41;$P = 0.041$). Multivariate analysis identified prediabetes, vitamin B9 deficiency, and binge eating disorder syndrome as independent factors associated with significant FFM loss ($P = 0.045$;OR = 7.48, $P = 0.012$;OR = 23.43, $P = 0.018$;OR = 10.93, respectively).
Conclusion
Our study highlights the importance of targeted nutritional and behavioral interventions to mitigate muscle loss in obese patients and enhance overall health outcomes in this population.

JOINT1951

A novel MED12 variant associated with early childhood-obesity

Chiraz Ghaddhab[1], Carine De Beaufort[1], Ulrike Schierloh[1], Nicolas Bonnet[1], Sylvie Bontemps[1], Michael Witsch[1] & Becker Marianne[1]
[1]Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg

Introduction
The *MED12* gene is located on the X chromosome and encodes a protein involved in the initiation of gene transcription. Pathogenic variants in *MED12* have been reported to cause three X-linked recessive syndromes (FG syndrome type 1, Lujan-Fryns syndrome and X-linked Ohdo syndrome) and one X-linked dominant syndrome (Hardikar syndrome). Pathogenic variants in *MED12* have been reported to cause nonspecific intellectual disability (NSID) and other neurological features as hypotonia, behavior issues, seizures as well as growth delays. Here, we report the case of an infant with precocious obesity and neurodevelopmental delay.
Case presentation
A 19-month-old female was seen in our outpatient clinic for pediatric obesity. She was the second child of Venezuelan parents, born at 38 weeks by caesarian section with a birth weight of 2.9kg (-0.75SDS). Her 5-year-old sister, was healthy and not overweight. At the referral, the patient weighted 13.4 kg (2.37SDS) for a length of 82 cm (0.1SDS), BMI 19.9kg/m^2 (2.63SDS). She had some dysmorphic features: prominent forehead, tented upper lip, protruding and backwardly rotated ears. At the clinical examination, she had a mild global hypotonia and was not yet walking. A blood analysis revealed normal cortisol, TSH and fT4. Genetic analysis, CGH and methylation profile of the 15q11q13 region were normal. Trio- exome sequencing revealed a de novo heterozygous mutation in the *MED12* gene (c.4453G > T, p.(Val1485Leu)). This variant is considered likely pathogenic by two prediction tools (Polyphen and SIFT).
Conclusion
Pathogenic variants in *MED12* have been already reported to cause various neurological symptoms and some have been also implicated as oncogenic in tumour tissue for leiomyoma or leiomyosarcoma. So far, only one female patient has been reported with a de novo *MED12* variant (c.4669T > C, p.Trp1557Arg) and severe obesity. This patient had obesity, neurodevelopmental delay and abnormalities of the corpus callosum. Some recent studies in Human adipose-derived stem cells hASCs and in murine models suggest that *MED12* could promote adipogenesis by acting as transcriptional coactivator for adipogenic genes and by repressing inhibitory pathways like Wnt signaling. Here we report another patient with a *MED12* de novo variant, presenting with precocious obesity and neurodevelopmental delay. Genetic counseling is very helpful in pediatric obesity clinics and exome sequencing is a powerful tool for identifying novel rare variants and understanding the pathogenesis of obesity in a subset of patients.

Comparison of glucose-insulin-metabolism indices in obese male and female adolescents with equivalent height-normalised visceral and subcutaneous adipose tissue areas

Lavinia La Grasta Sabolić[1,2], Ana Tripalo Batoš[3], Marijana Miler[1], Marija Požgaj Šepec[1,4] & Maja Cigrovski Berković[5]
[1]Sestre milosrdnice University Hospital Center, Zagreb, Croatia; [2]Catholic University of Croatia School of Medicine, Zagreb, Croatia; [3]Children's Hospital Zagreb, Zagreb, Croatia; [4]University of Zagreb School of Dental Medicine, Zagreb, Croatia; [5]Univeristy of Zagreb Faculty of Kinesiology, Zagreb, Croatia

Background
Obesity is a global health challenge affecting a significant number of adolescents worldwide. Abdominal obesity, in particular, is closely linked to insulin resistance and is a well-established risk factor for type 2 diabetes. Although differences in body fat distribution between boys and girls become pronounced during puberty, it remains unclear whether glucose-insulin metabolism and height-normalised abdominal fat indices differ between male and female adolescents with obesity.
Methods
This cross-sectional study included 90 obese adolescents (56 female). An oral glucose tolerance test (OGTT) was performed, and the following indices were calculated: the homeostatic model assessment of insulin resistance (HOMA-IR), insulin sensitivity index (ISI), insulinogenic index (IGI), and oral disposition index (oDI). Abdominal adipose tissue was estimated using single-slice magnetic resonance imaging (MRI) at the third lumbar vertebral level. Height-normalised visceral (VATa) and subcutaneous (SATa) tissue areas were used to derive the visceral adipose tissue index (VATI) and subcutaneous adipose tissue index (SATI). Sex differences in glucose-insulin metabolism, VATI, and SATI were assessed using the Mann-Whitney test.
Results
The participants had a median age of 14.8 years (range: 10.8–18) and a median body mass index (BMI) of 34.7 kg/m^2 (range: 25.2-54.4). Boys had significantly higher BMI z-scores ($p < 0.001$), VATa ($P = 0.030$), and SATa ($P = 0.023$) compared to girls. However, height-normalised VATI and SATI did not significantly differ between sexes ($P = 0.371$ and $P = 0.212$, respectively). Similarly, no significant differences were observed in HOMA-IR ($P = 0.339$), ISI ($P = 0.523$), IGI ($P = 0.382$), or oDI ($P = 0.247$) between boys and girls. Prediabetes was identified in 19 adolescents (13 female, 6 male), and type 2 diabetes was detected in one female adolescent.
Conclusions
Adolescents with obesity face a high risk of impaired glucose metabolism. However, no significant sex-based differences in glucose-insulin metabolism indices were found among obese adolescents with comparable VATI and SATI, despite differences in overall adiposity.

Metabolic syndrome and its components in overweight and obese children

Dhoha Ben Salah[1], Ameni Ben Abdallah[1], Khouloud Boujelben[1], Oumaima Dimassi[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Department of Endocrinology Hedi Chaker Hospital, Sfax, Tunisia

Background
although many studies have been conducted in adults to determine the prevalence and complications of the metabolic syndrome, few studies in children are available, particularly in developing countries. The aim of this study is to determinate the prevalence of the metabolic syndrome and its components in children and adolescents consulting the endocrinology department of the Hédi Chaker Hospital in Sfax, Tunisia, for exploration of overweight and obesity.
Methods
This cross-sectional study involved 84 obese and overweight children and adolescent, admitted to the endocrinology department of the Hédi Chaker Hospital in Sfax to explore overweight or obesity between 2015 and 2019.
Results
44 boys and 40 girls. The average age was 11.83 years (2-17). Family history of obesity was noted in 84.5% of cases. Seventy-seven percent had a family history of cardiovascular diseases. The average weight at the 1st visit was 72.68 kg (20-125 kg) with an average BMI of 31.55 kg/m^2. Obesity was reported in 78.6% of patients and overweight without obesity in 21.4% of cases. According to the criteria of NCEP ATP III adapted; 16.7% of patients had metabolic syndrome. La frequence des different criteres/Metabolic syndrome was observed in 15.9% of boys and 17.5% of girls, with no significant difference. Certain components, particularly abdominal obesity and hyperTG were far more prevalent.
Conclusion
The prevalence of metabolic syndrome was high in our study. we suggest targeted screening programs for at-risk children and adolescents in order to control obesity and metabolic syndrome in Tunisia.

Effect of gliflozins on serum fetuin-a in patients with type 2 diabetes and nonalcoholic steatohepatitis

Nadiia Protas[1], Iryna Kostitska[1], Yurii Protas[1] & Myroslav Lehun[1]
[1]Ivano-Frankivsk National Medical University, Communal Non-commercial Enterprise Regional Clinical Hospital of Ivano-Frankivsk Regional Council, Endocrinology, Ivano-Frankivsk, Ukraine

Background and aims
Particularly the association between type 2 diabetes (T2D) and comorbid disorders were linked to an increased risk of nonalcoholic steatohepatitis (NS). Early biomarker such as fetuin-A can help predict of insulin resistance, dyslipidemia and metabolic disorders in patients with NS. The use of gliflozins on hepatokines in patients with T2D and NS has encountered conflicting opinions. We aimed to compare the effectiveness of gliflozins on NS.
Materials and methods
36 participants with T2D and NS (58,3% males, 41,7% females; aged - 57,54 $\pm$ 9,24 years; duration of T2D-14,67 $\pm$ 5,14 years; body mass index (BMI)- 37,49 $\pm$ 4,32 kg/m^2; waist circumference (WC)-122,24 $\pm$ 11,32 cm; glycated hemoglobin (HbA_1C)-8,12 $\pm$ 0,23%; hepatic fibrosis (index FIB-4)-1,34 $\pm$ 0,25; METAVIR score at liver elastography-8,63 $\pm$ 0,46 kPa) were comprehensively investigation including physical examination, laboratory and instrumental results at baseline and 3 months following the treatment. Fetuin-A using kits for the enzyme-linked immune-sorbent assay. All patients were divided into three groups: Gr A ($n = 12$) received basic medical therapy (BMT) which included metformin (MET- 2000 mg/day), alpha-lipoic acid (600 mg/day) and rosuvastatin (10 mg/day) in combination with insulin therapy; Gr B ($n = 12$) subjects add-on to BMT and dapagliflozin (DAPA -10 mg/day); Gr C ($n = 12$) received BMT and empagliflozin (EMPA-10-25 mg/day).
Results
After 3 months of treatment the greater reduction in WC were observed in Gr B (-3,12 $\pm$ 0,04 cm, $P < 0,01$) and Gr C (-2,89 $\pm$ 0,02 cm, $P < 0,01$) vs compared to Gr A (-0,75 $\pm$ 0,02 cm), concurrently BMI decreased significantly in the subjects receiving DAPA (-1,92 $\pm$ 2,35 kg/m^2, $P < 0,05$) and EMPA (-1,22 $\pm$ 2,48 kg/m^2, $P < 0,05$). HbA_1C level was lowered by 0,76% (Gr A); 0,99% (Gr B) and 0,96% (Gr C). FIB-4 decreased significantly in patints of Gr B (1,28 $\pm$ 0,13 to 0,61 $\pm$ 0,05, $P < 0,01$) and Gr C (1,22 $\pm$ 0,19 to 0,63 $\pm$ 0,03, $P < 0,01$) that in the Gr A (1,27 $\pm$ 0,13 to 1,20 $\pm$ 0,08). Due to the positive result of METAVIR score was higher in subjects of Gr B (8,64 $\pm$ 1,33 vs 5,61 $\pm$ 0,25 kPa, $P < 0,01$) and Gr C (8,59 $\pm$ 1,45 vs 5,59 $\pm$ 0,32 kPa; $P < 0,01$) compared with the Gr A (8,49 $\pm$ 1,53 vs 7,74 $\pm$ 1,22 kPa). As regards to effect DAPA and EMPA on fetuin-A positive effect (0,8-0,9-time) in both groups. Fetuin-A was positively correlated with BMI ($r = 0,662$, $P = 0,004$), WC ($r = 0,758$, $P = 0,001$), FIB-4 ($r = 0,672$, $P = 0,003$) and METAVIR score ($r = 0,524$, $P = 0,002$). The gliflozins resulted in a decrease in content hepatic fibrosis, fetuin-A compared Gr A.
Conclusions
Our study demonstrated the positive effect of gliflozins activates additional hepatoprotective mechanisms and would become an innovation therapeutic option for the treatment of persons with NS.

Dapagliflozin protects against oxLDL-induced endothelial inflammation and oxidative damage by modulating the AMPK mechanism

Kun-Ling Tsai[1]
[1]National Cheng Kung University, Tainan, Taiwan

Atherosclerosis is a chronic cardiovascular condition characterized by the accumulation of oxidized low-density lipoprotein (ox-LDL) and the aggregation of vascular cells, leading to endothelial dysfunction and plaque formation. This study investigates the potential anti-atherogenic properties of Dapagliflozin (DAPA), a sodium-glucose cotransporter-2 inhibitor (SGLT2i) primarily used in managing type 2 diabetes (T2D). Recent clinical trials have highlighted DAPA's cardiovascular benefits, particularly in reducing heart failure and cardiovascular mortality, suggesting a broader therapeutic role beyond glucose regulation. In this study, we aim to explore the protective mechanism of DAPA in oxLDL-caused endothelial damage. The 150 μg/ml oxLDL dosage was stimulated to human umbilical vein endothelial cells (HUVECs) for 24 h with or without DAPA co-treatment. We found that DAPA increased the phosphorylation of AMPK in a dosage-dependent and time-dependent manner. DAPA reversed oxLDL-impaired cell viability by MTT assay. However, silencing AMPK by siRNA obliterates this finding. DAPA reduced oxidative stress markers, such as superoxide and

hydrogen peroxide production, under oxLDL stimulation. This reduction is regulated by AMPK-mediated NADPH oxidase activity and enhances the antioxidant defense system. We also found that DAPA mitigates oxLDL-induced apoptosis in endothelial cells by reducing intracellular calcium levels, stabilizing mitochondrial membrane potential, and modulating the expression of pro-apoptotic and anti-apoptotic proteins. Silencing AMPK by siRNA obliterates this finding. Together, those results contribute to developing novel therapeutic strategies for managing cardiovascular diseases related to atherosclerosis and providing insights into the broader clinical applications of SGLT2 inhibitors.

Challenges in the management of childhood obesity in primary care

Mouna Elleuch[1], Hamdi Frikha[1], Fatma Lachtar[1], Zaineb Fourati[1], Yosra Majdoub[2], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Preventive & Community Medicine, Sfax, Tunisia

Introduction
Lifestyle changes in industrialized societies have contributed to a rising prevalence of childhood obesity (CO). As frontline healthcare providers responsible for screening and family counseling, family physicians (FPs) face increasing challenges in addressing this silent epidemic. This study aims to explore the barriers to optimal CO management among FPs.
Methods
This was a cross-sectional descriptive and analytical qualitative study using a standardized questionnaire targeting FPs of all practice settings in southern Tunisia during 2024. Data were collected online or through direct interviews. Open-ended questions were assessed using a Likert scale from 0 to 10. The study focused on three main dimensions: CO management, patient adherence to treatment recommendations, and FP satisfaction. Statistical analysis was performed using SPSS software.
Results
We collected 100 responses from FPs with a mean age of 48.5 $\pm$ 11 years, predominantly female, with an average of 17.4 $\pm$ 11 years of practice experience. The main barriers to CO management were a lack of theoretical training (62%), patients' socioeconomic status (47%), and workload (30%). These challenges were more pronounced among physicians working in rural areas ($P = 0.03$) and in public healthcare settings ($P = 0.024$). Patient adherence to dietary and lifestyle recommendations provided by FPs was estimated at 4.5 $\pm$ 1.85/10 on average, with significantly lower adherence in private practice ($P = 0.01$), rural settings ($P = 0.0001$), and for dietary recommendations compared to physical activity advice ($P = 0.02$). Overall, FP satisfaction with CO management was below average (4.55 $\pm$ 1.9/10) and was significantly lower among private practitioners and those working in rural or semi-urban areas ($P = 0.003$ and $P = 0.045$, respectively).
Conclusion
Our study highlights disparities in CO management depending on the location and sector of FP practice. These differences suggest that access to resources, training, and specialized care networks directly impacts medical practices. The limited adherence of patients to dietary and lifestyle recommendations, particularly in rural areas, underscores the need for a more personalized approach tailored to socioeconomic constraints. Additionally, the low satisfaction among FPs regarding their ability to manage CO may reflect a lack of institutional support and excessive workload, hindering the implementation of effective strategies. These findings advocate for strengthening continuous medical education programs and improving healthcare structures to enhance CO management in primary care settings.

Phenotypic expression of biomolecular abnormalities in the leptin gene: a case report

Siddiqa Soomauroo[1], Nesrine Dhieb[1], AbdelMuhaymen Missaoui[1], Yasmine Abdelkafi[1], Dhoha Ben Salah[1], Khouloud Boujelben[1], Faten Hadjkacem[1], Nadia Charfi[1], Mouna Mnif[1], Mongia Hachicha[2], Mouna Elleuch[1] & Nabila Rekik[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Paediatrics, Sfax, Tunisia

Introduction
Over the past four decades, the prevalence of childhood obesity has increased drastically. Congenital leptin deficiency (CLD) is a very rare recessive genetic disorder caused by homozygous mutations in the *LEP* gene, leading to early-onset obesity. Children with CLD have a normal birth weight but rapidly gain weight within the first few months of life, resulting in severe hyperphagia and extreme obesity.
Objective
This study elucidates the phenotype associated with CLD through the report of an exceptional case involving a homozygous nonsense mutation in the exon of the leptin gene, of which only three other similar cases have been described.
Case Report
The patient, N.A., a 17-month-old girl, exhibited drastic weight gain from the age of 2 months, associated with an eating disorder characterized by severe hyperphagia. Her psychomotor development was normal, and she showed no signs of dysmorphic syndrome. The diagnosis was confirmed biologically by detecting a severely reduced circulating leptin level (< 1 ng/ml). Genetic analysis revealed a nucleotide change in exon 3 of the leptin gene, caused by a homozygous nonsense mutation in the *LEP* gene. Due to a lack of resources, our patient did not receive recombinant human leptin therapy. Managed solely with dietary and lifestyle interventions, her condition worsened, with an aggravation of the eating disorder, evolving into constant food-seeking behavior. By the age of 3 years and 7 months, she weighed 38 kg.
Conclusion
Given the genetic and therapeutic complexity of CLD cases, adaptations in healthcare pathways are necessary to alleviate both the socioeconomic burden of medical care and the financial strain on affected children and their families. To achieve this, frontline pediatricians must be trained and made aware of the importance of early detection of these rare cases. Additionally, significant efforts should be made to develop more accessible pharmacological leptin replacement therapy, ensuring that children in need can also benefit from treatment.

JOINT2018

Evaluation of phenotypic age to improve screening and prognosis in patients with type 2 diabetes mellitus

Olena Kolesnikova[1], Anastasiia Radchenko[1] & Vilena Chupina[2]
[1]L.T. Malaya Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine, Kharkiv, Ukraine; [2]Kharkiv National Medical University, Kharkiv, Ukraine

Background
According to the World Health Statistics 2024, diabetes mellitus (DM) remains a major metabolic risk factor for non-communicable diseases. Early screening and timely assessment of prognostic markers such as carotid artery stiffness (CAS), pulse wave velocity (PWV) in carotid and femoral arteries, carotid intima-media thickness (CIMT) are important for prevention of cardiometabolic complications. The use of phenotypic age (PA) is gaining popularity in clinical practice as it more accurately predicts age-associated changes than chronological age (CA).
Aim
The aim of our study was to evaluate the association of PA with cardiovascular risk factors compared with CA among patients with newly diagnosed type 2 diabetes mellitus (DM-2).
Methods
98 patients with type 2 DM (mean age 50.9 [47.5; 55.1] years) were compared with 20 age-reciprocal control patients (mean age 51.0 [48.4; 55.2] years) without DM-2. All patients were divided into two groups: aged <50 years and ≥ 50 years, based on CA ($n = 24$ vs $n = 74$, respectively) and PA ($n = 54$ vs $n = 44$), according to the method described by Levine *et al*., 2018. Anthropometrics, carbohydrate, lipid profiles, glomerular filtration rate (GFR), CAS, PWV and CIMT were assessed in all participants. The Mann-Whitney test was used to assess intergroup quantitative differences.
Results
There were significant differences in body mass index, carbohydrate and lipid profiles ($P < 0.01$), PA ($P = 0.001$), CAS ($P = 0.018$), PWV ($P = 0.0001$) and CIMT ($P = 0.0001$) between patients with newly diagnosed DM-2 and controls. Among all subjects with newly diagnosed DM-2, both CA and PA were associated with HOMA-IR ($r = 0.384$, $P = 0.0001$ and $r = 0.760$, $P = 0.003$), TC ($r = 0.620$, $P = 0.0001$ and $r = 0.825$, $P = 0.0001$), HDL-C ($r = 0.258$,

$P=0.003$ and $r = 0.562$, $P = 0.001$), LDL-C ($r = 0.612$, $P = 0.0001$ and $r = 0.814$, $P = 0.0001$), GFR ($r = 0.523$, $P = 0.001$ and $r = 0.869$, $P = 0.001$), CIMT (r 0.570, $P = 0.0001$ and $r = 0.836$, $P = 0.0001$). Meanwhile, CAS ($P = 0.027$), PWV ($P = 0.034$) and CIMT ($P = 0.0001$) were significantly higher in patients with newly diagnosed DM-2, in the PA subgroup $\geq$50 years. Glycated haemoglobin levels in the subgroup with PA <50 years were significantly higher than the subgroup of CA <50 years ($P = 0.001$), as was the HOMA-IR score ($P=0.01$).

Conclusions

Assessment of PA compared to CA in patients with DM-2 allows earlier diagnosis not only of disorders in carbohydrate metabolism, but also allows timely detection of the consequences of cardiometabolic changes based on CAC, PWV, CIMT than an increase in CA, which means preventing the addition of new patients with high and very high cardiovascular risk.

Background and objectives

The illicit use of anabolic androgenic steroids (AAS) has moved from competitive sports to the broader population and to women. The current knowledge on long-term impact of AAS in women is sparse. Women use AAS to gain a more muscular appearance and lose body fat but the impact on body composition has never been assessed. The objective of this study was to evaluate muscle and fat distribution in current and previous female illicit AAS users compared with never-users.

Methods

Cross-sectional study including women engaged in recreational strength training. Participants were grouped as current or previous users with a 3-month cut-off value for last AAS use. Dual-energy x-ray absorptiometry (DXA) was used to measure body composition with lean mass, fat mass and fat distribution.

Results

The study included 25 current AAS users, 14 previous users and 20 healthy never-users as controls. Mean (SD) age of all participants was 36 (9) years and mean (SD) body mass index was 24.7 (3.0) kg/m^2, with no difference between groups. Accumulated median (25th-75th percentiles) duration of AAS use did not differ between current and former users, 1.4 (0.3-4.5) vs 0.9 (0.6-1.9) years, ($P = 0.95$). The median (25th-75th percentiles) duration since AAS cessation among former users was 4.2 (1.8-5.6) years. Compared with controls, current AAS users displayed lower total body fat percent, 23.9 (4.0) vs 29.6 (5.1)% ($P <0.001$), and lower total fat mass, 15.5 (3.7) vs 19.9 (5.2) kg ($P = 0.002$). Current users also had a higher lean mass index than controls, 18.1 (2.4) vs 16.9 (1.4) kg/m^2 ($P = 0.038$), yet the fat distribution demonstrated a higher trunk to limb fat ratio, 0.78 (0.22) vs 0.63 (0.11) ($P= 0.006$). Notably, while total body fat percent, total fat mass and lean mass index did not differ between former users and controls, former users retained a higher trunk to limb fat ratio, 0.72 (0.12) vs 0.63 (0.11) ($P = 0.036$). There were no significant differences between groups when examining android to gynoid fat ratio and visceral adipose tissue.

Conclusions

Women previously engaged in illicit AAS use display increased trunk to limb fat ratio several years after cessation, suggesting long term adverse impact on fat metabolism.

The association between objectively meaured sleep duration and glucose regulation in healthy adolescents: insights from continuous glucose monitoring

David Horner[1], Kristen Evensen[1], Jonathan Thorsen[1], Bo Chawes[1], Klaus Bønnelykke[1], Jakob Stokholm[1], Rebecca Kofod Vinding[1] & Morten Rasmussen[1]
[1]COPSAC clinical research unit, Copenhagen, Denmark

Introduction

Sleep duration is increasingly recognised as a modulator of metabolic health, yet its acute effects on glucose regulation in healthy populations remain poorly understood. This study explores the relationship between sleep duration and post-sleep glucose metrics in healthy 18-year-olds.

Methods

This study included 206 participants (112 females, 94 males) from the COPSAC2000 cohort, with a mean age of 17.7 years. Sleep duration was assessed using actigraphy over a median of 13 nights per participant (IQR: 3), totaling 2,246 individual nights of sleep data. Concurrent glucose metrics (mean, median, variability) were derived from continuous glucose monitoring (CGM) during the waking period following each sleep measurement. Multivariate linear mixed-effects models, adjusted for age, sex, physical activity, social circumstances, and other confounders, were used to assess associations. Subanalyses focused on the 4-hour post-waking and 2-hour pre-waking periods to account for dietary confounding and the cortisol awakening response.

Results

Females slept longer on average than males (6:56 vs. 6:25 h,$P < 0.001$) and had earlier sleep onset times (00:10 vs. 00:50,$P < 0.001$). In multivariable modelling, longer sleep duration (per hour of sleep) was associated with higher mean ($\beta = 0.28$, 95% CI: 0.05–0.52) and median glucose levels ($\beta = 0.39$, 95% CI: 0.15–0.63) and reduced glucose variability (SD: $\beta = -0.12$, 95% CI: -0.23 to -0.01; CV: $\beta = -0.16$, 95% CI: -0.28 to -0.04). Associations for glucose levels were stronger in the 4-hour post-waking window (mean: $\beta = 0.56$, 95% CI: 0.29–0.83; median: $\beta = 0.66$, 95% CI: 0.37–0.94). In the 2-hour pre-waking period, glucose levels rose at a population level by 10mg/dL (0.6mmol/l), consistent with the cortisol awakening response. This rise in glucose may explain why longer sleep duration was associated with higher pre-waking glucose variability (SD: $\beta = 0.27$, 95% CI: 0.09–0.45; CV: $\beta = 0.29$, 95% CI: 0.09–0.48). Mediation analysis revealed that the morning glucose slope partially mediated the association between sleep duration and median glucose levels (indirect effect: 0.019, 95% CI: 0.0015–0.0448). Effect sizes were modest and unlikely to be clinically meaningful.

Conclusion

Sleep duration is associated with glucose levels and variability in healthy adolescents, with longer sleep linked to higher waking glucose and lower variability. The pre-waking glucose rise underscores the role of circadian rhythms in glucose dynamics. While these findings provide mechanistic insights, the modest effect sizes suggest limited clinical relevance in this healthy cohort.

LDL-cholesterol calculation methods influence on clinical management

sébastien magnifico[1,2], Abdallah Al-Salameh[1] & Antoine Galmiche[1]
[1]Chu Amiens, Amiens, France; [2]Chu Amiens Picardie Hospital, Amiens, France

Introduction

Most clinical laboratories use the Friedewald equation to account for VLDL-cholesterol and subsequently calculate LDL-cholesterol. This equation has known limitations at high triglyceride levels or low LDL-cholesterol levels. Alternative equations, such as the Martin-Hopkins and Sampson-NIH equations, have been proposed. This study aims to compare LDL-cholesterol estimates derived from these three equations with directly measured LDL-cholesterol and to assess whether the choice of equation affects patients' clinical management.

Methods

In this retrospective, monocentric study, all LDL-cholesterol samples analyzed at Amiens University Hospital between august 1st, 2022 and July 31st, 2023 were included ($n = 7895$). LDL-cholesterol levels calculated by the three equations were compared with measured LDL values using Pearson correlation coefficient. Comparisons were stratified by total triglyceride (TG) (0-400 mg/dL, 400-800 mg/dL and >800 mg/dL) and LDL-cholesterol levels (below or above 70 mg/dL). Subsequently, random samples were selected from each category (TG 0-400 mg/dL, TG 400-800 mg/dL and LDL-cholesterol <70 mg/dL), cardiovascular risk was estimated for each individual and the misclassification rates attributable to each equation were determined.

Results

In the TG 0-400 mg/dL category, all three equations yielded equivalent correlation coefficients ('r') around 0.95 but the Sampson equation showed the highest concordance rate (24.85% vs 22,01% for Martin-Hopkins 20.45% for Friedewald). In the TG 400-800 mg/dL category, the correlation coefficients ('r') was around 0.83 and both the Martin-Hopkins and Sampson-NIH equations had the highest concordance rates (14.51% and 13.70% vs 3.22% for Friedewald). In the LDL-cholesterol <70 mg/dL category, The Martin-Hopkins and Sampson-NIH equations had correlation coefficients ('r') of 0.70 and 0.71, respectively,

compared to 0.61 for Friedewald; concordance rates were 27.55% for the Martin-Hopkins, 26.78% for the Sampson-NIH and vs 24.25% for the Friedewald equation. Among people with TG 0-400 mg/dL, the proportion of misclassified individuals was 4,4% for the Sampson-NIH, 4,9% for the Martin-Hopkins and 6,4% for the Friedewald equation. Among people with TG 400-800 mg/dL, the proportion of misclassified individuals was 7,4% for the Sampson-NIH, 3,7% for the Martin-Hopkins and 14,8% for the Friedewald equation. The respective proportions were 14,7%, 14,7% and 17,6% among individuals with LDL-cholesterol $<$70mg/dL.

Conclusion

This study demonstrates that the three methods perform very well in people with TG 0-400 mg/dl, relatively good in people with TG 400-800 mg/dL and less well in people with LDL-cholesterol $<$ 70 mg/dL. However, the Sampson and Martin-Hopkins equations are less prone to therapeutic misclassification errors than the Friedewald equation.

Exploration of metabolic signatures or biomarkers associated with obesity in children and adolescents

Diamanto Koutaki[1], Garyfallia Stefanou[2], Sofia-Maria Genitsaridi[1], Eleni Ramouzi[1], Athanasia Kyrkili[3], Meropi D. Kontogianni[3], Eleni Kokkou[1], Eleni Giannopoulou[1], Penio Kassari[1,4] & Evangelia Charmandari[1,4]

[4]Center for the Prevention and Management of Overweight and Obesity in Childhood and Adolescence, Division of Endocrinology, Metabolism and Diabetes, First Department of Pediatrics, School of Medicine, National and Kapodistrian University of Athens, 'Aghia Sophia' Children's Hospital, Athens, Greece; [2]ECONCARE - Health Research & Consulting, Athens, Greece; [3]Department of Nutrition and Dietetics, School of Health Sciences and Education, Harokopio University of Athens, Athens, Greece; [4]Division of Endocrinology and Metabolism, Center of Clinical, Experimental Surgery and Translational Research, Biomedical Research Foundation of the Academy of Athens, Athens, Greece

Introduction

Obesity is an escalating health issue globally, impacting both adults and children. Despite its prevalence, the precise mechanisms driving the development of obesity in children remain unclear. Metabolomics, the comprehensive study of metabolites within biological systems, offers a powerful approach to better define the phenotype and understanding the complex biochemical alterations associated with obesity.

Aim

The aim of our study was to summarize the current knowledge in the field of metabolomics in childhood obesity, and to identify metabolic signatures or biomarkers associated with obesity in children and adolescents (within the framework of the BIO-STREAMS project (https://www.bio-streams.eu/); a 4-year (2023–2027) Horizon Europe project (No101080718)).

Methods

We performed a systematic search of Medline and Scopus databases according to PRISMA guidelines. The review was registered in the International Prospective Register of Ongoing Systematic Reviews (PROSPERO 2023 CRD42023494461). We included only longitudinal prospective studies, randomized-controlled trials with $\geq$12-month follow up, and meta-analyses of the above that assessed the relation between metabolic signatures related to obesity and body mass index (BMI) or other measures of adiposity in children and adolescents aged 2-19 years with overweight or obesity. Initially, 595 records were identified from PubMed and 1565 from Scopus. After removing duplicates and screening for relevance, 157 reports were assessed for eligibility. From the additional search, 75 new records were retrieved, from which none was eligible for our study. Finally, 7 full-text articles were included in our study.

Results

The majority of the included studies stated an association of lipids with changes of BMI, insulin resistance and the risk for metabolic syndrome. More specifically, these include certain lipoproteins, apolipoproteins, cholesterols, fatty acids, glycerides and phospholipids, ketone bodies, lysophosphatidylcholines as well as acyl–alkyl phosphatidylcholine. Among the overarching class of amino acids, peptides and analogues, included are glycylproline, citrulline, formiminoglutamic acid, 4-hydroxyproline, alanine, phenylalanine, tyrosine, gluta-mine, methionine, serine and alanine. Furthermore, numerous lipids act as signaling molecules in inflammation pathways or insulin resistance, contributing to obesity-related complications, such as DM2 and cardiovascular disease. Acylcarnitines are the by-products of noncomplete fatty acid oxidation.

Conclusion

Our findings reveal specific biomarkers in the amino acid and lipid pathway that could serve as early indicators of obesity and its related cardiometabolic complications. Continued exploration of metabolomic profiles in childhood obesity is warranted, particularly in pediatrics, to develop targeted interventions and prevent the long-term consequences of this condition.

JOINT2648

Comparative accuracy of glycemic parameters in identifying dysglycemia in obese indian children and adolescents

Alapan Mahapatra[1], Manoj Agarwal[2], Anurag Bajpai[1], Vibha Yadav[1] & Dhvani Raithatha[1]

[1]Regency CDER, Pediatric Endocrinology, Kanpur, India; [2]Shalby Hospital, Ahmedabad, India

Background-

Dysglycemia is a significant cause of concern in children and adolescents with obesity. The beneficial impact of early intervention makes timely identification desirable. The current diagnostic cutoffs for dysglycemia based on adult recommendations have not been validated in Indian children and adolescents. In particular, the validity of hemoglobin A1C (HbA1C) cutoffs has been questioned.

Aim

To compare the diagnostic accuracy of glycemic parameters (glucose tolerance test, HBA1C, and continuous glucose monitoring measures) in identifying dysglycemia in obese Indian children and adolescents.

Methodology

An oral glucose tolerance test and HbA1C were performed in 170 obese children and adolescents (110 boys; age 12.8 $\pm$ 3.2 and BMI SDS 2.3 $\pm$ 0.6). Twenty subjects also underwent 14-day ambulatory blood glucose monitoring. The prevalence of dysglycemia according to different measures and the correlation between different parameters were compared. A ROC curve was generated to determine the diagnostic cutoff of HbA1C to identify glucose tolerance test-detected dysglycemia.

Results

Dysglycemia was identified by eight subjects according to fasting glucose (all pre-diabetes, 4.7%), fifteen as per 2-hour value (13 with prediabetes, 2 with diabetes; 8.8%), and 37 by to HbA1C (36 with pre-diabetes and 1 with diabetes, 21.8%). Twenty-eight subjects (77.8%) identified as pre-diabetes by HbA1C had normal glucose tolerance tests. Both the subjects with abnormal glucose profiles on continuous glucose monitoring (16.2%) had glucose tolerance tests determined dysglycemia. Average blood glucose in CGM data correlated with fasting (r = 0.9, P = 0.001) and 2-hour blood glucose (r = 0.8, p=$<$0.001) with no correlation with HBA1c (r = 0.5, P = 0.09). The ROC curve for diagnostic efficacy of HbA1C in identifying dysglycemia had an area under the curve of 0.730 (P = 0.02). An increase in HBA1C cutoff to 6% would have avoided the diagnosis of dysglycemia in 8 subjects with normal glucose tolerance tests.

Conclusion

Dysglycemia is common in Indian children and adolescents, highlighting the need for early identification. HbA1C tends to overestimate dysglycemia, suggesting the need for higher cutoffs. ABGM is a promising tool for screening dysglycemia but needs further exploration before widespread use.

Screening accuracy of single-point insulin sensitivity estimator (SPISE) for metabolic syndrome: a systematic review and meta-analysis

Alireza Azarboo [1], Parisa Fallahtafti[1], Sayeh Jalali[1], Amirhossein Shirinezhad[1], Ramin Assempoor[1] & Amirhossein Ghaseminejad-Raeini[1]

[1]School of Medicine, Tehran University of Medical Sciences, Tehran, Iran

Background

Metabolic syndrome (MetS) is a multifactorial condition linked to increased risk of cardiovascular disease and type 2 diabetes. Insulin resistance underpins its pathophysiology, yet traditional diagnostic methods are invasive and costly. The Single-Point Insulin Sensitivity Estimator (SPISE), a non-invasive index, offers a practical alternative for assessing insulin sensitivity. This systematic review and meta-analysis aim to evaluate the diagnostic accuracy of SPISE in detecting MetS.

Methods
We conducted a systematic review and meta-analysis following PRISMA guidelines. We searched databases such as MEDLINE, Scopus, Web of Science, and Embase, focusing on studies evaluating SPISE's screening accuracy for MetS. Eligible studies were observational, reporting mean SPISE values and its diagnostic performance. Meta-analyses were performed using Hedges' g standardized mean differences (SMD) and pooled area under the curve (AUC) estimates.
Results
Seven studies comprising 12,919 participants were included. Individuals with MetS had significantly lower SPISE scores than controls (SMD = -0.94, 95% CI: -1.25 to -0.63). The pooled AUC for SPISE as a predictor of MetS was 0.86 (95% CI: 0.83 to 0.90), surpassing other insulin sensitivity indices like HOMA-IR and the triglyceride/HDL-C ratio. Meta-regression showed that systolic and diastolic blood pressure were potential sources of heterogeneity.
Conclusions
SPISE is a highly accurate and non-invasive tool for predicting MetS, potentially outperforming traditional indices like HOMA-IR. Its ease of use and diagnostic precision make it a valuable clinical screening tool, especially in diverse populations.

ACTH as the liver fibrosis predictor in non-cushing syndrome population

Mari Minasyan[1], Wiktoria Suchy[2], Joanna Kokoszka[3], Alicja Hubalewska-Dydejczyk[1], Elena Valassi[4,5] & Aleksandra Gilis-Januszewska[1]
[1]Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland; [2]Students' Scientific Group of Endocrinology, Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland., Kraków, Poland; [3]Department of Endocrinology, Oncological Endocrinology and Nuclear Medicine, University Hospital, Kraków, Poland; [4]Endocrinology Department, Hospital Germans Trias i Pujol, Badalona (Barcelona), Spain, Barcelona, Spain; [5]Universitat Internacional de Catalunya (UIC), Barcelona, Spain

Introduction
The data on the impact of adrenocorticotropic hormone (ACTH) and cortisol on liver function are scarce and conflicting. To the best of our knowledge there are no studies evaluating cortisol and ACTH as liver fibrosis (LF) biomarker in non-Cushing syndrome (CS).
Objectives
To evaluate the role of ACTH and cortisol in LF among non-CS.
Materials and Methods
We analyzed retrospectively 350 consecutive patients (66%female, median age 65 [56-70]) with non-secretive adrenal adenomas. CS was excluded on 1 mg dexamethasone suppression test (C-DST [morning cortisol <1.8 mg/dL]). FIB4 (Age$\times$AST/PLT$\times$ALT 1/2) was used as a LF predictor (<1.3 low risk [LR-LF], 1.3-2.67 intermediate risk [IR-LF], >2.67 high risk [HR-LF]). Multimodal logistic regression analyses were performed (RStudio version 4.2.2, $P<0.05$). Age, gender, bmi diabetes mellitus and hypercholesterolemia were included as co-variates to account for its potential influence on FIB-4.
Results
For every 1, 2, 10 and 30pg/ml ACTH rise, the odds for IR-LF rise by 3%, 6%, 16%, 35% and 148% ($P = 0.039$) and for HR-LF increase by 6%, 13%, 35%, 83% and 517% $P = 0.006$). The OR for the association between LF and cortisol (morning, midnight, C-DST) was statistically non-significant.
Conclusions
ACTH may have an impact on LF in non-CS population. Further studies examining the relation between ACTH, cortisol and liver fibrosis are needed.

Metabolic bariatric surgery reduces markers of aging in patients with obesity, independent of achieving optimal total weight loss

Alicja Dudek[1,2], Barbara Zapała[3], Ilona Kawa[3], Karol Ciszek[3], Piotr Tylec[1], Katarzyna Cyranka[4], Piotr Major[1] & Wojciech Zgliczynski[5]
[1]Jagiellonian University Medical College, II Department of General Surgery, Krakow, Poland; [2]Postgraduate Medical Education Center, Endocrinology Department, Warsaw, Poland; [3]Jagiellonian University Medical College, Krakow, Poland; [4]Jagiellonian University Medical College, Department of Diabetes and Metabolic Diseases, Krakow, Poland; [5]Postgraduate Medical Education Center., Endocrinology Department, Warsaw, Poland

Introduction
Obesity is a chronic metabolic disorder associated with accelerated biological aging, systemic inflammation, and oxidative stress. Metabolic bariatric surgery (MBS) is an effective intervention for obesity; however, the extent to which improvements in biological age markers are contingent upon achieving optimal weight loss remains unclear.
Objective
To investigate whether the postoperative changes in aging biomarkers following MBS are dependent on achieving optimal weight loss outcomes.
Methods
In this prospective observational study, 100 patients with obesity scheduled for MBS between July 2020 and May 2021 were enrolled and followed for 24 months postoperatively. Biological aging markers assessed included telomere length (TL) measured by quantitative polymerase chain reaction (qPCR), DNA damage, C-reactive protein (CRP), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), total oxidant status (TOS), and metabolic age. Patients were stratified into two cohorts: those achieving optimal weight loss (% total weight loss [TWL] $\geq$20%, % excess weight loss [EWL] $\geq$50%) and those with suboptimal weight loss outcomes (%TWL $<$20%, %EWL $<$50%). Correlations between weight loss parameters and changes in biological aging markers were analyzed.
Results
Forty patients completed the 24-month follow-up (22 in the optimal weight loss group, 18 in the suboptimal group). Significant postoperative improvements were observed in TL, DNA damage, CRP, IL-6, TNF-α, TOS, and metabolic age in both cohorts. Notably, metabolic age demonstrated a significantly greater reduction in the optimal weight loss group ($p < 0.05$), whereas changes in other biomarkers did not differ significantly between groups.
Conclusions
MBS induces significant reductions in biomarkers associated with biological aging, independent of the extent of weight loss achieved. These findings suggest that conventional weight loss metrics (%TWL, %EWL) may not fully capture the therapeutic benefits of MBS, underscoring its broader impact on molecular aging processes.

Weight evolution in children of mothers with gestational diabetes: an analysis of the early years of life

Rita Pinto Ribeiro[1], Rita Alves[2], Patrícia Brito[1], Mafalda Noronha[2], Ana Rita Marinho[3], Olinda Marques[1] & Henedina Antunes[4]
[1]ULS Braga, Endocrinology Department, Braga, Portugal; [2]ULS Braga, Nutrition Department, Braga, Portugal; [3]Faculdade de Ciências da Nutrição e Alimentação da Universidade do Porto, Porto, Portugal; [4]Pediatric Gastroenterology, Hepatology and Nutrition Unit and Clinical Academic Center, 2CA-Braga, ULSBraga; Life and Health Sciences Research Institute (ICVS); ICVS/3B's, Associate Laboratory and School of Medicine, University of Minho, Braga, Portugal

Introduction
Gestational diabetes (GD) is associated with metabolic complications and an increased risk of childhood obesity. This study aimed to analyze weight evolution and factors associated with overweight and obesity in children of mothers with GD, as well as to identify maternal factors that influence weight gain during the early years of life.
Methods
This retrospective cohort study included 186 mothers diagnosed with GD and their offspring, born between January 2018 and December 2019 at our center. Sociodemographic and clinical data of the mothers were collected, including pre-pregnancy body mass index, weight gain during pregnancy, type of GD treatment, and data on the children, such as anthropometric measurements up to the age of 6, breastfeeding practices, and neonatal health parameters. Weight/length z-scores and BMI z-scores were calculated for the children at different age ranges. Associations between maternal and child variables and the children's weight evolution up to 6 years were tested.

Results
The mean (SD) age of the mothers was 34.7 (5.7) years, with an average (SD) pre-pregnancy BMI of 24.4 (5.2) kg/m^2. A total of 44.6% of the women required pharmacological treatment for glycemic control. Births were 62.4% vaginal deliveries and 37.6% cesarean sections. During the follow-up of the children, 5.0% were found to be overweight, and 4.4% were obese between the ages of 4 and 6. In the adjusted model, the presence of a family history of diabetes and earlier introduction of complementary feeding were associated with a higher BMI z-score at ages 4-6 years ($\beta = 0.442$, 95% CI: 0.087, 0.796; $\beta = -0.249$, 95% CI: - 0.448, -0.051, respectively).
Conclusion
This study suggests that having family history of diabetes is associated with a higher risk of overweight and obesity in children of mothers with GD. The introduction of complementary feeding closer to 6 months appears to be associated with a lower risk of obesity. These findings reinforce the importance of early preventive strategies and continuous monitoring of the weight evolution in these children.

Bariatric surgery and conception timing: maternal and neonatal outcomes

Renata Barbosa[1], Beatriz Tavares da Silva[1], Susana Garrido[1], Ariana Maia[1], Liliana Fonseca[1], Joana Vilaverde[1], Maria Teresa Pereira[1], Diana Martins[2], Fernando Pichel[3] & Jorge Dores[1]
[1]Endocrinology Department, Centro Hospitalar e Universitário de Santo António, ULS Santo António, Porto, Portugal; [2]Obstetrics and Gynaecology Department, Centro Materno-Infantil do Norte Albino Aroso, ULS Santo António, Porto, Portugal; [3]Department of Nutrition, Centro Hospitalar e Universitário de Santo António, ULS Santo António, Porto, Portugal

Introduction
The recommended interval between bariatric surgery and conception varies, generally ranging from 12 to 24 months. Some studies associate conception within two years post-surgery with an increased risk of preterm delivery, neonatal intensive care unit(NICU) admission, and small-for-gestational-age(SGA) newborns. However, other studies show no significant differences.
Objective
To evaluate the impact of the interval between bariatric surgery and conception ("early conception", $\leq$12 months vs "late conception", $>$12 months) on pregnancy outcomes.
Materials and Methods
A retrospective study was conducted on pregnancies following bariatric surgery at a Portuguese tertiary center. Maternal and neonatal complications were compared between two groups based on surgery-to-conception interval. Composite maternal complications included preeclampsia, polyhydramnios, and miscarriages, while composite fetal complications encompassed preterm births, need for phototherapy, and admission to the NICU. Statistical analyses were performed using IBM SPSS Statistics.
Results
The study included 102 pregnancies (92 women) between 2015 and 2023. The median maternal age was 34 years (23-45). Most patients underwent gastric bypass (66.7%, $n = 68$), while 33.3% ($n = 34$) had sleeve gastrectomy. The median surgery-to-conception interval was 34 months, with 22.5% ($n = 23$) conceiving within 12 months post-surgery. The median gestational age at delivery was 39 weeks (23-41), and the median birth weight was 3030g (1000-4140g). The cesarean section rate was 33.0%. Pregnancy complications included 12 cases (12.2%) of preeclampsia, 2 cases (2.1%) of polyhydramnios, 3 miscarriages (3.1%) and 15 preterm births (15.6%). Neonatal outcomes included 20 large-for-gestational-age newborns (20.8%), 11 SGA (11.5%) and 11 congenital malformations (11.5%). Additionally, 28(29.2%) required phototherapy, and 9(9.4%) were admitted to the NICU. No statistically significant differences were found between groups in terms of maternal-fetal complications, whether analyzed individually or as composite outcomes(Table 1).

Table 1. Pregnancy outcomes in early *vs* late conception group

	Early conception ($n = 23$)	Late conception ($n = 79$)	p-value
Cesarean section(n, %)	7(33.3)	25(32.9)	0.970
Preeclampsia(n, %)	1(4.8)	11(14.3)	0.452
Polyhydramnios(n, %)	1(5.0)	1(1.3)	0.378
Miscarriages(n, %)	2(9.5)	1(1.3)	0.120
Preterm births(n, %)	1(5.0)	14(18.4)	0.183
Large-for-gestational-age(n, %)	4(20.0)	16(21.1)	0.918
SGA(n, %)	1(5.0)	10(13.2)	0.449
Congenital malformations(n, %)	1(5.0)	10(13.2)	0.449
Need for phototherapy(n, %)	8(40.0)	20(26.3)	0.273
Admission to the NICU(n, %)	0(0)	9(11.8)	–
Maternal complications(n, %)	4(19.0)	13(17.6)	0.876
Fetal complications(n, %)	9(45.0)	31(40.8)	0.801

Conclusion
While current guidelines recommend delaying conception, our findings suggest that pregnancy within one-year post-surgery may be safe. However, the small sample size may have limited the ability to detect significant differences, highlighting the need for further studies.

A rare syndrome hidden behind obesity

Andjela Boskovic[1], Marija Miletic[1], Milina Tancic Gajic[1], Zorana Arizanovic[1], Natalija Pavlovic[1], Milica Jovanovic[1], Taisa Bojovic[1] & Svetlana Vujovic[1]
[1]University Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Belgrade, Serbia

Introduction
Obesity is a chronic and complex disease that can affect your overall health and quality of life. A number of conditions could be hidden behind obesity. Pseudohypoparathyroidism (PHP) is a rare inherited disorder characterized by end-organ resistance or unresponsiveness to parathyroid hormone (PTH) resulting in increased serum PTH levels, hypocalcemia and hyperphosphatemia. Physical features of PHP are specific somatic and developmental abnormalities such as round facies with a 'short, thick figure', heterotopic subcutaneous ossifications (SCOs), brachydactyly and cognitive impairment.
Case report
We present a female patient who consulted with us in her late twenties due to extreme obesity. Her menarche was at age 13, after which her menstruations have always been irregular according to the type of oligomenorrhea, with the longest period without menstruation being of 3 months. In childhood, she was examined for obesity under the suspicion of hypercortisolism, which was ruled out. She gained weight in early childhood, with a maximum of 120 kg at the age of 12. Psychological examination showed mild cognitive impairment. During the physical examination we identified general obesity type with phenotypic characteristics of AHO (Albright hereditary dystrophy): brachydactyly, short stature, stocky habitus, macrocephaly, round face, short fingers on both hands, except for thumbs, SCOs in the pretibial region of lower extremities. Hand radiography showed shorter metacarpal bones of the fourth finger bilaterally with discrete degenerative changes. Cranial and chest radiography, neck and abdominal ultrasound, and ophthalmological examination were normal. Bone density was normal. Karyotype was 46, XX. Calcium and phosphorus homeostasis were intact with elevated calcitonin and PTH.
Consusion
Patients with PHP faces a wide range of problems due to hormone resistance that can lead to hypothyroidism, hypogonadism, growth impairment, ectopic ossifications, cognitive disorders and obesity. This highly heterogeneous clinical picture requires a multidisciplinary approach.

Distribution of lipid levels and prevalence of hyperlipidemia in a multi-ethnic young male population

Jonathan Han YongJun[1], Gerald Sng Gui Ren[1], Lee Yong Qin[2], Tan Hong Chang[1], Bee Yong Mong[1] & Lim Huai Yang[3]
[1]Department of Endocrinology, Singapore General Hospital, Singapore, Singapore; [2]Medical Classification Centre, Central Manpower Base, Singapore, Singapore; [3]Singapore Armed Forces Medical Corps, Singapore, Singapore

Introduction
The prevalence of hyperlipidemia among adolescents and young adults is rising globally, contributing to an increased risk of atherosclerotic cardiovascular

disease (ASCVD) later in life. Identifying dyslipidemia requires understanding normal lipid ranges, which prior studies have defined in discrete age brackets: childhood and adolescence ($\leq$19 years) and young adulthood (20-40 years). However, lipid concentrations likely change continuously with age. This study aims to describe lipid levels and associated factors in a population-wide cohort of multi-ethnic Asian males aged 16-25 years who underwent mandatory military health screening.

Methods

The study included more than 19,000 males aged 16-25 years eligible for military conscription from 1 July 2021 to 30 June 2022. Data collected comprised anthropometric variables (height, weight, body mass index [BMI], body fat percentage), clinical measures (blood pressure), and non-fasted lipid levels (total cholesterol [TC], triglycerides [TG], high-density lipoprotein cholesterol [HDL-C]). Low-density lipoprotein cholesterol (LDL-C) was estimated using the Friedewald equation. Subgroup analysis was performed on older adolescents (16-19 years). Hyperlipidemia prevalence was determined using National Cholesterol Education Program (NCEP) Adult Treatment Panel III criteria for the overall cohort and NCEP Pediatric Panel criteria for older adolescents.

Results

The mean lipid values were: TC (4.38 mmol/l), TG (1.23 mmol/l), HDL-C (1.37 mmol/l), and LDL-C (2.46 mmol/l). Nearly 44% of participants were overweight or obese. Body fat percentage and blood pressure were positively correlated with TC levels. The prevalence of hyperlipidemia was significant: 12.5% had TC $>$5.2 mmol/l, 19% had TG $\geq$1.7 mmol/l, 5.1% had HDL-C $<$1.0 mmol/l, and 35.6% had LDL-C $>$2.6 mmol/l. The prevalence of severe hypercholesterolemia (LDL-C $\geq$4.9 mmol/l) was 0.6%, and severe hypertriglyceridemia (TG $\geq$4.5 mmol/l) was 0.5%. Familial hypercholesterolemia was diagnosed in 0.3% of participants. In the older adolescent subgroup, 16.2% had abnormal TC levels, and 8.2% had abnormal LDL-C levels.

Conclusion

We described the lipid distribution in a population-wide cohort of Asian males aged between 16 to 25 years old. Unsurprisingly, mean lipid values appear to be between that described in childhood and adult populations. While the high proportion of older adolescents with dyslipidemia may be due to normative differences in that age range as compared to younger children, it is also matched by similarly high prevalence of dyslipidemia even when using adult thresholds - suggesting that the true prevalence of hyperlipidemia is indeed high and may portend future cardiovascular risk.

Semaglutide as a potential treatment for a child with ADCY3 mutation

Aylin Tugba Canbaz[1], Bahar Ozcabi[2], Samim Ozen[3], Abdullah Bereket[1] & Belma Haliloglu[1]

[1]Marmara University School of Medicine, Department of Pediatric Endocrinology and Diabetes, Istanbul, Türkiye; [2]Acibadem Atasehir Hospital, Department of Pediatric Endocrinology and Diabetes, Istanbul, Türkiye; [3]Ege University School of Medicine, Department of Pediatric Endocrinology and Diabetes, Istanbul, Türkiye

Aim

ADCY3 mutations, a rare cause of monogenic obesity, are associated with hyperphagia, obesity, insulin resistance, hyposmia, and intellectual disability. Although no specific treatment is approved, GLP-1 receptor agonists have shown potential benefits. Here, we present our experience with Semaglutide in a patient with an *ADCY3* mutation.

Case

A $4^{7/12}$ years-old female presented with hyperphagia and excessive weight gain starting at 2 months. She was born at term with a birth weight of 3050g ($-$0.08 SDS), her weight increased to 6.5 kg ($+$2.03 SDS) at 2 months,19 kg ($+$6.98 SDS) at 10 months, and 34 kg ($+$8.42 SDS) at 2.5 years. The family had a history of consanguinity but no reported obesity. At presentation, her height was 118.5 cm ($+$2.59 SDS), weight 64 kg ($+$7.86 SDS), and BMI 45.5 ($+$5.70 SDS). Physical examination revealed severe acanthosis nigricans, Blount's disease impairing ambulation, stage 2 hypertension with left ventricular hypertrophy, atypical autism, and astigmatism. Laboratory findings are summarized in Table-1. Whole Exome Sequencing identified a novel homozygous warm variant of uncertain significance in the *ADCY3* gene (c.1102G$>$A), confirmed by segregation analysis. Due to uncontrolled hyperphagia, rapid weight gain, and severe obesity-related complications, treatment with Semaglutide was initiated at a dose of 0.125mg/week. The dose was titrated to 0.50mg/week at monthly intervals, as no adverse effects were observed. The patient's weight stabilized after 1 month at 0.50mg/week. As hyperphagia persisted without adverse effects, the dose was increased to 1 mg/week. During the first month at this dose, she lost 4.4 kg, and her weight remained stable over the following 3 months. Her BMI-SDS improved from $+$5.54 SDS to $+$4.88 SDS at seventh month of treatment (Table-2). The patient is currently under follow-up without experiencing significant adverse effects.

Table 1. Laboratory findings

	Result	Range
Fasting-Glucose(mg/dL)	79	70–100
Insulin(μIU/ml)	34.8	2–25
Hba1c(%)	5.6	4.8-5.9
TSH(mIU/L)	2.5	0.54-4.53
Free-T4(pmol/L)	18.6	11-22.5
Total Cholesterol(mg/dL)	171	8-200
HDL(mg/dL)	56	40-60
Triglyceride(mg/dL)	70	0-150
Leptin(ng/ml)	74	12-135
AST/ALT(U/L)	43/41	7-35

Table 2. Treatment Progress and Outcomes with Semaglutide

	Semaglutide Dose(mg/-week)	Weight-SDS	Height-SDS	BMI(kg/m^2)	BMI-SDS
Base-line($4^{10/12}$ years-old)		7.90	2.24	48.0	5.54
1st-month	0.125	8.01	2.12	49.8	5.51
2nd-month	0.25	8.14	2.01	51.2	5.44
3rd-month	0.5	7.47	2.82	44.6	5.14
6th-month	1.00	7.14	2.48	46.3	4.95
7th-month	1.00	6.96	2.40	45.6	4.88

Conclusion

GLP-1RA may be considered a potential treatment option for patients with *ADCY3* mutations presenting with uncontrolled hyperphagia, excessive weight gain, and severe obesity-related complications.

Assessing allostatic load as a chronic stress marker in adolescents with anorexia nervosa: the impact of malnutrition

Vittoria Carlotta Magenes[1], Lucia Labati[2], Virginia Rossi[1], Nadia Fratangeli[3], Valentina Fabiano[1,4], Leonardo Mendolicchio[3], Gianvincenzo Zuccotti[1,4] & Valeria Calcaterra[1,5]

[1]Buzzi Children's Hospital, Department of Paediatrics, Milan, Italy; [2]Buzzi Children's Hospital, Department of Biomedical and Clinical Sciences, Milan, Italy; [3]I.R.C.C.S. Istituto Auxologico Italiano, Experimental Laboratory for Metabolic Neurosciences Research, Piancavallo, Italy; [4]University of Milan, Department of Biomedical and Clinical Science, Milan, Italy; [5]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy

Introduction

Allostatic load (AL) refers to the physiological response associated with the burden of chronic stress. Malnutrition is an important source of physiological stress that promotes a detrimental chronic low-inflammation state. In order to define a correlation between cumulative biological dysregulation and severe malnutrition, we measured AL scores in in adolescents with AN

Patients and Methods

We enrolled 40 adolescents (15,99 $\pm$ 1,40 yrs) with AN. Data based on 15 biomarkers were used to create the AL score. A dichotomous outcome of high AL was defined for those who had $\geq$2 dysregulated components (aligning with the population median). Body mass index (BMI)-standard deviation score (SDS) $<$-3and biochemical markers ($\geq$2) defined severe malnutrition.

Results

High AL and severe malnutrition were noted in 31/40 (77.5%) and 9/40 (22.5%) subjects respectively. Subjects with a high AL, in addition to a lower BMI z-score (P =0.02), showed higher triglycerides (P = 0.03), ALT (P $<$ 0.01), AST (P = 0.01) and lower VitD (P $<$0.01) and Vit B12 (P = 0.02) levels than subjects with a low AL. The risk of the cumulative biological dysregulation is correlated with severity of malnutrition (P =0.02). The AUROC of malnutrition upon detection of cumulative biological dysregulation was 0.759.

Conclusions
A high AL was associated with severe malnutrition in AN. AL may be considered a significant factor correlated with increased morbidity in adolescents who present AN.

Is gender affirming hormone therapy a risk factor for liver health? - 1-year follow-up data from a prospective study

Gesine Meyer[1], Anne-Sophie Fath[1], Kerstin Jacobs[1], Eva Herrmann[2] & Jörg Bojunga[1]
[1]Goethe University Frankfurt, University Hospital, Medical Clinic 1, Division of Endocrinology and Diabetes, Frankfurt, Germany; [2]Goethe University Frankfurt, Institute of Biostatistics and Mathematical Modelling, Frankfurt, Germany

Objective
Evidence about hepatic risk profile of gender affirming hormone therapy (GAHT) is low. Most previous studies are small, retrospective and focused on the assessment of liver enzymes. Our objective was to challenge fewer findings with prospective data using modern investigation methods. We analysed the impact of GAHT on metabolic risk factors and on the development of pathological remodeling in the liver
Design
Prospective cohort study in 39 transgender individuals (20 transmen and 19 transwomen). Data were collected from 2021 to 2023.
Methods
Sonographic examinations including CAP (controlled attenuation parameter) measurement and transient elastography, the current non-invasive gold standard methods to evaluate the development of metabolic-associated fatty liver disease (MAFLD) and MAFLD-related fibrosis, were performed in all participants. Furthermore, we assessed parameters of glucose and lipid metabolism. Data were gathered each before and one year after initiation of GAHT. A relevant increase, respectively decrease was defined, if values changed $>$ 50 % of the respective standard deviation of the baseline value.
Results
Median age of the participants was 24.3 $+$ 7.2 years. 16.7 % of the cohort were obese, defined by a BMI $\geq$ 30 kg/m^2. While BMI increased during the first year of GAHT ($P = 0.024$), we could exclude an increase of fasting glucose ($P < 0.001$) as well as HbA1c ($P = 0.006$). In transmen, we recorded an increase in LDL- ($P = 0.016$) and a decrease in HDL-cholesterol ($P < 0.001$), however, all parameter remained within the reference range. Triglycerides showed a trend to increase in transmen and to decrease in transwomen, but results were not significant and parameter remained within the reference ranges. Sonographic methods could exclude an increase of liver steatosis ($P = 0.001$) as well as fibrosis ($P < 0.001$).
Conclusion
Neither virilising nor feminising gender affirming hormone therapy is a risk factor for the development of MAFLD or MAFLD-related fibrosis within the first year. A further measurement after five years of therapy will per performed to evaluate long-term effects.

Gene diagnostic challenge of extreme early-onset obesity before 5 years old

Si Chen[1] & Xinran Cheng[1]
[1]Chengdu Women's and Children's Central Hospital, Chengdu, China

Background
Clinical parameters, such as differential white blood cell counts, are linked to metabolic diseases and insulin resistance. However, the closely clinical markers associated with early-onset obesity, particularly genetic obesity, remain undefined. Given the increasing consensus around the necessity of genetic testing for severe early-onset obesity, there's a need to enhance the efficacy of such tests. This study endeavors to distinguish between hereditary and non-hereditary obesity using clinical indicators. The goal is to offer a foundation for the early diagnosis of hereditary obesity and subsequent genetic screening. Therefore, we conducted this observational study.
Methods
We identified early-onset obesity in children below five years old, defined by a BMI exceeding the 95th percentile. Recommended interventions included hospitalization for comprehensive obesity assessments encompassing physical examinations, biochemical tests, hormone levels, and genetic screenings.
Results
When compared to the negative Whole Exome Sequencing (WES) group, six distinct gene mutations were identified in the positive WES group: BBS1, MC4R, NCOA1, SH2B1, UCP3, and 15q11-13. This group also demonstrated a significant increase in differential white blood cell count, monocytes, serum ALT, AST, and cortisol levels ($P < 0.05$).
Conclusions
By examining disparities in clinical indicators, this research highlights the potential for genetic obesity screening in early-onset cases. Our findings provide valuable insights for the clinical genetic testing of early-onset obesity.
Keywords
Early-onset obesity, genetic detection, gene mutations, monocyte, white blood cell count.

Patients with early-onset monogenic obesity: genetic approach and therapeutic challenges

Kyriaki Hatziagapiou[1,2], Eleni Koniari[1], Eirini Kostopoulou[3], Konstantina Georgoulia[1], Feneli Karachaliou[2] & George Chrousos[1]
[1]University Research Institute for Maternal and Child Health and Precision Medicine, National and Kapodistrian University of Athens, 'Aghia Sophia' Children's Hospital, Athens, Greece; [2]Unit of Pediatric Endocrinology, Diabetes and Metabolism, Third Department of Pediatrics, National and Kapodistrian University of Athens, School of Medicine, Attikon General Hospital, Athens, Greece; [3]Division of Paediatric Endocrinology and Diabetes, Department of Paediatrics, School of Medicine, University of Patras, Patras, Greece

Introduction and Purpose
Children with severe, early-onset obesity before the age of 5, accompanied by extreme episodes of hyperphagia, should be investigated for monogenic forms of obesity. The MC4R (melanocortin-4 receptor) pathway orchestrates the energy homeostasis, and deficiencies along the pathway may cause monogenic obesity. MC4R pathway deficiencies include mutations in the genes encoding leptin (*Lep*) and its receptor (*LepR*), pro-opiomelanocortin (*POMC*), MC4R, prohormone convertase subtilisin/kexin type 1 (*PCSK1*), nuclear receptor coactivator 1 (*NCOA1*), and SH2B Adaptor Protein 1 (*SH2B1*). The aim is to present three cases of children with early-onset obesity and to explore its genetic basis.
Patients and Methods
Three male patients were included aged $11^{7/12}$, $8^{10/12}$, and $9^{3/12}$ years at their first visit to the Endocrinology Units. Detailed family and personal history was taken, along with comprehensive laboratory and imaging tests. Due to the early onset of obesity, resistance to dietary restrictions, and exercise, a suspicion of monogenic disease was raised. DNA analysis was performed using an obesity panel with next-generation sequencing (NGS) technology.
Results
All patients exhibited severe, early-onset obesity with hyperphagia and hepatic steatosis. From early infancy, they showed a strong interest in food intake, with a gradual increase in body mass index (BMI). Despite efforts to modify their lifestyle (changes in dietary habits, exercise, and psychological support), no improvement in BMI was observed. The first patient exhibited a potentially pathogenic variant, NM_005912:exon1:c.380C$>$T:p.S127L, in the *MC4R*, which was also confirmed in the father. It may disrupt MC4R function by altering its expression on the cell membrane and its biophysical properties. In the second child, the rs17782313 NC_000018.9:g.57851097T$>$C polymorphism in the MC4R gene was detected in heterozygous form. The polymorphism is significantly associated with hyperinsulinemia and severe obesity. Disruption of the transcriptional control of MC4R has been proposed as the potential functional mechanism for this variant. In the third child the variant of unknown significance NM_003743.5: c.3954C$>$T p. (Thr1318$=$) was detected in heterozygosity in the *NCOA1* gene. In all children, the administration of metformin did not help control appetite or BMI. Following the genetic test results, treatment with setmelanotide will be initiated, which is approved for children with syndromic or monogenic obesity associated with the hypothalamic MC4R pathway.
Conclusions
The study demonstrates the importance of genetic investigation of children with the two hallmark symptoms of early-onset, severe obesity and hyperphagia,

enabling timely selection of appropriate therapeutic approaches, prevent obesity consequences, and provide genetic counseling.

Successful reversion of vision loss in dysthyroid optic neuropathy (DON) by adjuvant diuretic therapy

Judit Kaluha[1], Ágnes Diószegi[1], Bernadett Ujhelyi[2], Sándor Barna[3], Edit Nagy[4], Emese Csiki[5], Eszter Berta[1], Endre V. Nagy[1] & Miklós Bodor[1]
[1]Division of Endocrinology, Department of Medicine, Debrecen, Hungary; [2]Departments of Ophthalmology, Debrecen, Hungary; [3]Nuclear Medicine, Debrecen, Hungary; [4]Medical Imaging, Debrecen, Hungary; [5]Oncology, Debrecen, Hungary

Thyroid eye disease (TED) is the most frequent extrathyroideal complication of Graves' disease. Severe, sight threatening TED poses a risk of complete vision loss and requires treatment with high dose intravenous methylprednisolone and, in the absence of an immediate response, urgent orbital decompression surgery.

Case Presentation

A 77-year-old female patient was presented at the Thyroid-Eye Clinic in Debrecen in May 2024 due to progressive vision deterioration and eyelid swelling. Upon examination, the visual acuity of the right and left eyes were 0.0 and 0.1 respectively. The diagnosis of TED was confirmed by elevated TRAb level (11.5 U/L), and by MRI and ^{99m}Tc-diethylenetriamine pentaacetic acid (DTPA) SPECT/CT imaging. Clinical activity score (CAS) was 5 on the 7 item scale in both sides which, in combination with the high DTPA uptake, indicated active GO. Orbital MRI revealed optic nerve compression in both sides, with more severe apical crowding in the right side. According to our institutional protocol, in addition to standard of care including high-dose intravenous glucocorticoids and orbital irradiation, parenteral diuretic therapy was initiated, while the patient was closely monitored by the multidisciplinary team. During follow up, visual acuity of the left eye gradually improved from the initial 0.1 to 0.9, while vision did not return in the right eye. Proptosis by Hertel-score decreased from the initial 17 and 19 mm to 12 and 13 mm, right and left eye, respectively. This is the second report of a patient in whom the addition of intravenous diuretics to the standard glucocorticoid treatment facilitated the decrease in orbital pressure, and orbital decompression surgery could be avoided.

JOINT3455

A rare case of hypertriglyceridaemia in infancy secondary to lipoprotein lipase deficiency

Sabrina Sheridan[1], Verena Gounden[2], Damian Griffin[2], Karen Haverin[2], Niamh mgrath[1] & Joanne Nelson[1]
[1]University Hospital Galway, Department of Paediatrics, Galway, Ireland; [2]University Hospital Galway, Department of Chemical Pathology, Galway, Ireland

Background

Lipoprotein lipase (LPL) deficiency is a rare genetic disorder of lipid metabolism. The LPL enzyme induces the hydrolysis of triglycerides from lipoproteins to generate free fatty acids. LPL deficiency results in severe hypertriglyceridemia and chylomicronaemia and is associated with recurrent pancreatitis (1).

Case Presentation

We report the case of a previously well male infant, who presented at 6 months of age with fever, vomiting and dehydration. He was admitted for intravenous rehydration. His CRP and urea were unanalysable as the blood sample was lipaemic. Subsequent testing revealed a cholesterol of 9.26mmol/l (3.0-5.0) and triglycerides of 34.6 mmol/l (0.4-2.0). His family history was significant for a paternal history of hypercholesterolaemia and fatty liver disease. Both of his parents are members of the Irish travelling community and are third cousins. Repeat bloods tests two days later showed a downtrending cholesterol (3mmol/l) and triglycerides (4.5mmol/l). His HDL cholesterol was low 0.46mmol/l (1.0-2.0) and he had normal liver function. He clinically improved and was discharged home with planned outpatient follow-up. He was readmitted 2 weeks later with poor feeding and a tender abdomen. His bloods were lipaemic with a raised lipase 181IU/L (13-60), raised triglycerides 22.6mmol/l and raised cholesterol 6.3mmol/l. His amylase and liver function tests were within normal limits. Following this he was diagnosed with acute pancreatitis and suspected familial chylomicronaemia syndrome, most commonly associated with LPL deficiency. This male infant was transitioned to Monogen, a formula low in long-chain triglycerides and solid fat intake was restricted with supplementation of fat soluble vitamins. His target triglyceride level is $<$10mmol/l. His triglycerides (2.6mmol/l) and cholesterol (3.7mmol/l) levels have remained low on this diet and at 2 years old he is growing well along the 75thto 91st centile for height and weight.

Results

Genetic testing revealed that he was Heterozygous for the variant c.897_1018+1939dup p.? in the lipoprotein lipase gene. Parental samples have been sent and are pending.

Discussion

Familial LPL deficiency is a rare disorder. We report the only case in the Republic of Ireland associated with this mutation. This genetic variant has been detected in five individuals in the Amsterdam UMC laboratory, only two of these, like our case, had hypertriglyceridaemia. Restriction of dietary fat is usually sufficient to reduce chylomicronaemia and hypertriglyceridaemia. Drugs that lower lipids levels in the body are ineffective in these cases.

Semaglutide treatment in hypotalamic obesity

Emmanuele Capobianco[1,2], Cristina Sciacovelli[1,2], Ercole Franco[1,2], Federica Pippa[1,2], Federica Delfini[1,2], Ida Sicilia[1,2], Beatrice Baldini[1,2], Silvia Garelli[1] & Uberto Pagotto[1,2]
[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [2]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy

Introduction

Hypothalamic obesity (HO) is a rare and severe form of obesity due to hypothalamic damage, often resulting from neurosurgical interventions. It is characterized by alterations in food control mechanisms and decreased energy expenditure, resulting in refractory weight gain. HO is unresponsive to conventional weight loss strategies like lifestyle modifications, pharmacotherapy, and bariatric surgery. GLP-1 receptor agonists (GLP-1RAs) represent a successful pharmacological paradigm to treat general obesity delaying gastric emptying and improving satiety by multiple mechanisms. We present three cases of HO successfully treated with off-label weekly semaglutide.

Case 1

A 36-year-old female with panhypopituitarism and diabetes insipidus secondary to multiple craniopharyngioma surgeries developed severe HO. She reached a maximum weight of 138.5kg (BMI 44.7), that was managed with sleeve gastrectomy in 2017. Her weight dropped to 119kg but gradually returned to 138kg (June 2024). At this point we started semaglutide (0.25mg to 2.4mg). The result was a 16kg weight loss (-11.6%) reaching 122kg (BMI 39.4) in just six months (date of the last visit).

Case 2

An 18-year-old male with panhypopituitarism and diabetes insipidus post-craniopharyngioma surgery in 2020 developed HO. Before surgery, he weighed 75kg (BMI 28.6) dropped to 54kg due to hyporexia. After surgery, he rapidly gained weight, reaching 97kg (July 2021) and 123kg (BMI 46.9) by June 2022. Semaglutide (0.25mg to 2mg) led to a 26.8% weight loss, reaching 91kg by March 2023, weight maintained to this day. He reported improved appetite control and no significant adverse effects.

Case 3

A 16-year-old female with panhypopituitarism following craniopharyngioma double resection (2019, 2020) developed HO, with weight increasing from 51.2kg (BMI 22.5) to 75kg (BMI 33.0). Due to progressive and refractory weight gain, semaglutide was started in 2023 (0.25mg to 1mg), leading to significant weight reduction (-27.3%), reaching 54.5kg (BMI 24.8) by December 2023. By January 2025, her weight stabilized at 62kg (BMI 28.5). The only side effect was mild nausea.

Discussion

Although GLP-1RAs' efficacy is well-documented in general obesity, their role in HO remains under investigation. These cases align with recent real-world studies, showing significant weight loss with semaglutide, alongside improved appetite regulation. Long-term treatment appeared necessary to maintain weight loss. Semaglutide's effects could extend beyond hypothalamic signalling, involving extrahypothalamic pathways such as the brainstem and vagus nerve. Advances in obesity treatment, including dual and tri-agonists, could represent a promising

approach for achieving significant weight loss and improved appetite control without major side effects even in HO patients.

Clinical follow-up data of patients diagnosed with obesity

İlkem Gardiyanoğlu Akçay[1], Erdal Kurnaz[1], Melikşah Keskin[1], Kezibaan Aslı Bala[1] & Şenay Savaş Erdeve[1]
[1]Ankara Etlik City Hospital, Pediatric Endocrinology, Ankara, Türkiye

Objective
Childhood obesity is a growing public health concern worldwide, posing long-term risks such as type 2 diabetes, hypertension, dyslipidemia, and cardiovascular diseases. Effective treatment strategies primarily focus on lifestyle modifications(LSM), with pharmacological interventions considered in resistant cases. This study aims to assess the effectiveness of LSM alone vs LSM combined with metformin therapy in children diagnosed with obesity at Ankara Etlik City Hospital. By analyzing anthropometric and biochemical changes over a one-year follow-up, this study seeks to contribute to the development of optimal treatment strategies for pediatric obesity management.
Materials and Methods
This retrospective study included 162 pediatric patients between 5-18 years, diagnosed with exogenous obesity, who were followed at the Pediatric Endocrinology clinic for one year. Patients were categorized into two groups: those receiving only LSM and those receiving LSM + metformin therapy. Collected data included demographic characteristics, body mass index(BMI), fasting blood glucose(FBG), lipid profile and liver function tests. These parameters were measured at baseline and at 3, 6, 9, and 12 months, with statistical analyses conducted to evaluate intra-group and inter-group differences over time.
Results
Among 162 patients, 52.29% were male and 47.71% were female, with a mean age of 12.49 ± 3.19 years. Both groups showed only a limited reduction in BMI, with no significant improvements in waist circumference, systolic blood pressure, or diastolic blood pressure over the study period. However, a significant decrease in BMI SDS was observed in the LSM group between baseline and the third month, but this reduction was not sustained in subsequent follow-ups. Both groups exhibited significant reductions in fasting blood glucose (FBG) and HbA1c levels, with greater reductions in the LSM + metformin group, a difference that was statistically significant. LDL cholesterol levels significantly declined only in the LSM + metformin group, while other lipid parameters showed no significant changes. The proportion of metabolically unhealthy obesity (MUO) increased in the LSM-only group, whereas in the LSM + metformin group, MUO prevalence significantly decreased from 86.67% to 67.86% over 9 months.
Conclusion
This study highlights the critical role of regular follow-ups in obesity treatment, emphasizing that adherence is essential for long-term success. While metformin therapy provided additional metabolic benefits, its effect on BMI reduction was minimal. Personalized treatment approaches, family involvement, and structured patient education programs may enhance adherence and improve long-term outcomes. Ultimately, effective obesity management requires a multifaceted approach that combines medical intervention with continuous behavioral support and patient engagement.

Predicting models in patients with COVID-19 and metabolic syndrome

Olena Antonyuk[1,2,3]
[1]Bogomolets National Medical University, Kapital Ltd., National Military Medical Clinical Center "Main Military Clinical Hospital", of Public Health, Ky, Ukraine; [2]Kapital Ltd., Kyiv, Ukraine; [3]National Military Medical Clinical Center "Main Military Clinical Hospital", Clinic of Hematoology with Wards for Intensive and Chemotherapy, Kyiv, Ukraine

Background
Patients with metabolic syndrome have a significantly higher risk of severe COVID-19 complications, such as in-hospital mortality and acute kidney injury (AKI). The combination of chronic low-grade inflammation, endothelial dysfunction, and metabolic dysregulation worsens clinical outcomes, increasing the need for early risk assessment and targeted management strategies.
Aim
This study aimed to evaluate mortality and AKI risk in hospitalized COVID-19 patients by developing predictive models and proposing targeted interventions to improve patient outcomes.
Methods
A retrospective case-control study was conducted on 129 hospitalized COVID-19 patients from 2020 to 2021. Patients were classified into survivors ($n = 88$) and non-survivors ($n = 41$) for mortality risk analysis, while the AKI group included 19 patients with kidney injury and 110 without. Logistic regression models were developed and validated using receiver operating characteristic (ROC) analysis. The mortality model included respiratory insufficiency (OR 22.6; $P < 0.001$), lymphocyte count (OR 0.000144; $P < 0.001$), C-reactive protein (CRP) (OR 1.2; $P < 0.001$), minimal albumin (OR 0.716; $P < 0.001$), eGFR minimum (OR 0.951; $P < 0.001$), and lung involvement on MSCT above 50% (OR 4.96; $P < 0.001$). The AKI model incorporated respiratory insufficiency (OR 12.3; $P < 0.001$), PADUA score ≥ 4 (OR 3.9; $P < 0.01$), CRP > 100 mg/L (OR 2.7; $P = 0.02$), and hyperglycemia (OR 1.8; $P = 0.04$). The models were implemented as web-based calculators and Excel tools to assist clinical decision-making.
Results
Metabolic syndrome significantly influenced outcomes. Patients with respiratory insufficiency had a 22.6-fold increased risk of mortality and a 12.3-fold increased risk of AKI. Hyperglycemia and obesity contributed to AKI risk, reinforcing the need for tight metabolic control, including glucose maintenance below 10 mmol/l, early insulin therapy, and SGLT2 inhibitors for renal protection. CRP levels above 100 mg/L were strongly associated with both mortality (OR 1.2, $P < 0.001$) and AKI (OR 2.7, $P = 0.02$), supporting the benefit of early anti-inflammatory therapy such as IL-6 blockade with tocilizumab and metformin continuation if tolerated. The mortality risk calculator achieved an AUC of 0.976 (95% CI 0.951-1) with 95% sensitivity and 92.6% specificity, while the AKI model had an AUC of 0.848 (95% CI 0.731-0.944), with 89% sensitivity and 80% specificity. Obese patients demonstrated mortality risks comparable to elderly individuals, emphasizing the need for hospitalization criteria based on MetS severity rather than age alone.
Conclusion
Metabolic syndrome is a critical determinant of COVID-19 severity, significantly increasing mortality and AKI risk. The predictive models developed in this study offer high accuracy and practical clinical application, allowing for early identification of high-risk patients.

Unraveling factors behind childhood obesity

Mouna Elleuch[1], Yesmine Elloumi[1], kouloud boujelben[2], Ines Ketata[3], Mouna Aboub[4], Mouna Mnif[2], Dhoha Ben Salah[1] & Nabila Mejdoub Rekik[1]
[1]Hedi Chaker University Hospital, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology department, Sfax, Tunisia; [3]Ben Arous Hospital, Tunis, Tunisia; [4]Bir Ali Hospital, Bir Ali, Tunisia

Background
Childhood obesity and overweight have become pressing global health concerns, with an ever-growing number of children affected. These conditions carry profound consequences for both physical and mental health, making them a critical issue for society. The underlying causes of this epidemic are multifaceted. This study seeks to explore and uncover the primary drivers of childhood obesity and overweight.
Methods
This cross-sectional case-control study, conducted in 2022, involved children from school health clinics in Tunis, Tunisia. Participants aged 5 to 15 years were included, with exclusions for conditions causing secondary obesity. Overweight was classified as an age-specific BMI $>$ 1 standard deviation (SD) above the WHO growth standards median, while obesity was defined as a BMI $>$ 2 SDs above the median. According to the WHO, early diversification of diet is defined as starting before the age of 6 months. The children were divided into two groups: G1 (overweight or obese) and G2 (normal weight). A 41-item questionnaire was distributed to both children and their parents to assess obesity risk factors.
Results
The study included 216 participants, with 54 classified as overweight or obese (G1) and 162 as having a normal weight (G2). While no significant relationship was found between the occurrence of overweight or obesity and age ($P = 0.07$), it was significantly higher in male children ($P = 0.038$). The presence of allergies in G1 was not significant ($P = 0.200$). The average birth weight was higher in G1 (3400g) compared to G2 (3000g) ($P = 0.01$). The average duration of

breastfeeding was longer in G1 although the difference was not significant ($P = 0.800$). The duration of artificial feeding was not associated with childhood obesity ($P = 0.08$). The practice of having meals at the table was similarly observed in both groups ($P = 0.91$). Obesity was less frequently observed in children who had their meals in a daycare setting ($P = 0.47$). No significant association was found between watching TV during meals and the presence of obesity or overweight in children ($P = 0.92$). G1 consumed more fast food ($P = 0.539$) and G2 engaged in more physical activity outside of school ($P = 0.894$). Additionally, no significant correlation was found between TV time and the presence of obesity or overweight in children ($P = 0.9$).

Conclusion

Tackling the underlying causes of childhood obesity and overweight, with a focus on understanding and addressing key contributing factors, is essential to reversing this escalating epidemic.

Assessment of nutritional status in obese adults undergoing weight loss interventions

Sana Khamassi[1], Fatma Boukhayatia[1], Haifa Abdesselem[1], Emna Bornaz[1], Kamilia Ounaissa[1], Rahma Mahjoub[2], Houda Bouhajja[3], Amel Gammoudi[4], Awatef Kacem[4], Emna Talbi[3], Jamoussi Henda[4] & Chiraz Amrouche[1]

[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology, Clinical Biology Laboratory, Tunis, Tunisia; [3]National Institute of Nutrition and Food Technology, Obesity Reserach Unit, Tunis, Tunisia; [4]National Institute of Nutrition and Food Technology, UR17SP01-Clinical Biology Laboratory, Tunis, Tunisia

Background

Obesity is associated with a paradoxical nutritional imbalance, where excessive energy intake often coexists with deficiencies in essential micronutrients. This imbalance contributes to an increased risk of various comorbidities and mortality in obese patients. The aim of our study was to assess the nutritional status in a population of obese adult patients.

Methods

This is a descriptive, cross-sectional observational study involving 100 obese adult patients. Body composition was assessed using a SECA MBCA 515 bioelectrical impedance analysis. Dietary data were analyzed using Nutrilog software. The diagnosis of sarcopenic obesity (SO) was established according to the latest consensus proposed by ESPEN and EASO [1].

Results

The mean age was 44.42 ± 13.25 years with a sex ratio (M/F) of 0.11. The mean BMI was 40.07 ± 5.77 kg/m^2, with morbid obesity identified in 48% of the patients. The mean arm muscle circumference was 32.31 ± 3.01 cm and 26.06 ± 3.34 cm, respectively in male and female patients with 82% of patients exhibiting normal values. The mean skeletal muscle mass and appendicular skeletal muscle mass were 26.83 ± 6.63 kg and 16.07 ± 4.06 kg, respectively. A decrease in fat-free mass index was noted in 20% of patients. The average muscle strength was 39.14 ± 11.79 kg in male patients and 23.40 ± 5.79 kg in female patients with muscle strength impairment observed in 21% of the patients. SO was diagnosed in 19% of the study population. Biological nutritional assessment revealed anemia in 18% of patients, hypophosphatemia in 4% of patients, 25(OH) vitamin D insufficiency was found in 37% and deficiency in 62% of patients. The mean albumin level was 41.91 ± 2.31 g/L, with normal albumin and calcium levels in all patients. Dietary survey data analysis revealed a hypercaloric intake in the majority of patients (75%), a high carbohydrate intake in 48%, a high lipid intake in 93%, and a low protein intake in 9% of patients. The majority of the study population had insufficient intake of EPA (95%) and DHA (96%). Micronutrient deficiencies were mainly marked by deficiencies in vitamin A (90%), vitamin D (88%), calcium (55%), vitamin B9 (44%), and vitamin C (32%).

Conclusion

The results of our study highlight the critical need for a comprehensive nutritional assessment in obese patients to detect malnutrition or associated nutritional deficiencies, and to optimize their management.

Phase angle as a predictor of nutritional status in middle-aged obese patients

Sana Khamassi[1], Fatma Boukhayatia[1], Haifa Abdesselem[1], Emna Bornaz[1], Kamilia Ounaissa[1], Nesrine Dhieb[2], Sana Hammami[3], Houda Bouhajja[4], Amel Gammoudi[2], Awatef Kacem[2], Emna Talbi[4], Jamoussi Henda[2] & Chiraz Amrouche[1]

[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology, Obesity Reserach Unit, Tunis, Tunisia; [3]National Institute of Nutrition and Food Technology, Clinical Biology Laboratory, Tunis, Tunisia; [4]National Institute of Nutrition and Food Technology, UR17SP01-Clinical Biology Laboratory, Tunis, Tunisia

Background

In the context of obesity, phase angle (PhA) is considered a potential marker for evaluating health status and monitoring weight loss interventions [1]. Research has shown that higher PhA values are associated with improved nutritional status. The aim of our study was to evaluate the relationship between PhA and nutritional status in obese patients.

Methods

This is a cross-sectional study conducted on 100 obese patients. Body composition was assessed using SECA MBCA 515 bioimpedance and low PhA was defined as $< 6°$. Muscle strength was assessed by measuring grip strength using a digital dynamometer. Dietary survey data were analyzed using Nutrilog software.

Results

The mean age was 44.42 ± 13.25 years, with female predominance (90%). The mean BMI was 40.07 ± 5.77kg/m^2. The mean fat mass and fat mass index values were 52.50 ± 12.39kg and 19.74 ± 4.03kg/m^2, respectively. The average PhA was $5.11 \pm 0.54°$ and the majority of patients had a low PhA (94%). Specifically, 56% of patients had a PhA between 5 and 6, 35% had a PhA between 4 and 5, only one patient had a PhA below 4, and 6% had a PhA above 6. PhA showed a positive correlation with skeletal muscle mass ($r = 0.30$; $P = 0.002$), appendicular muscle mass ($r = 0.25$; $P = 0.012$), fat-free mass ($r = 0.25$; $P = 0.011$), and muscle strength ($r = 0.45$; $P = 0.015$). Additionally, PhA was inversely correlated with fat mass (r=-0.48; $P < 0.0001$). The nutritional biological assessment revealed a positive correlation with albumin levels ($r = 0.26$; $P = 0.009$). The dietary survey indicated a positive correlation between daily protein intake and PhA ($r = 0.27$; $P = 0.006$), with significant correlations for both animal proteins ($P = 0.015$) and plant-based proteins ($P = 0.04$). Furthermore, the analysis of micronutrient intake revealed positive correlations between PhA and the intake of several micronutrients, including vitamin B3 ($r = 0.20$; $P = 0.047$), vitamin B5 ($r = 0.22$; $P = 0.039$), vitamin B6 ($r = 0.23$; $P = 0.021$), vitamin B12 ($r = 0.20$; $P = 0.049$), calcium ($r = 0.25$; $P = 0.012$), phosphorus ($r = 0.26$; $P = 0.01$), and iron ($r = 0.20$; $P = 0.049$).

Conclusion

The findings of our study suggest that PhA may serve as a useful marker for assessing nutritional health and guiding interventions in obesity management.

Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark; [10]Department of Internal Medicine Horsens Regional Hospital, Horsens, Denmark

Introduction
Fermented dairy products have been associated with a reduced risk of type 2 diabetes, but the mechanisms remain unclear. Oral lactate has previously been shown to increase insulin levels and delay gastric emptying in healthy individuals. This study investigated whether orally administered lactate affects glucose tolerance, insulin secretion, appetite, and gastric emptying in individuals with pre-diabetes during an oral glucose tolerance test (OGTT).
Methods
In a double-blind, randomized crossover design, 12 individuals with pre-diabetes (HbA1c 39–47 mmol/l) were studied twice after an overnight fast using a 75 g glucose solution: 1) with 25 g sodium lactate (LAC) added, and 2) with a placebo (iso-osmotic sodium chloride, CTR) added. Blood samples and appetite questionnaires were collected, and gastric emptying was assessed using the paracetamol absorption test.
Results
Lactate increased plasma lactate concentrations to 2.6 mmol/l compared to 1.5 mmol/l on the placebo day (incremental area under the curve (iAUC), $P < 0.001$). No differences were observed between interventions for glucose iAUC (-53 (95%CI: -189-86) mmol x min/L, $P = 0.42$). Insulin concentrations were similar, but C-peptide concentrations trended to be higher on the lactate day compared to the placebo day (iAUC: 62 (95% CI: -2–125) nmol x min/L, $P = 0.06$). No differences were observed between interventions regarding paracetamol absorption or appetite sensations.
Conclusion
Oral lactate did not improve glucose tolerance in individuals with pre-diabetes and had no effect on insulin secretion, appetite, or gastric emptying. This indicates that adding lactate into carbohydrate-rich meals is unlikely to reduce postprandial glucose excursions in individuals with pre-diabetes.

JOINT2056
Genetic analysis of pediatric severe obesity in a single japanese instituition

Jun Mori[1], Yoh Watanabe[1], Yuki Yamada[1] & Shinji Higuchi[1]
[1]Osaka City General Hospital, Children's Medical Center, Division of Pediatric Endocrinology, Metabolism and Nephrology, Children's Medical Center, Osaka, Japan

Background
Childhood and adolescent obesity is increasing, and childhood obesity often persists into adulthood. The causes of obesity are complex, involving environmental, social, and genetic factors. Genetic factors are estimated to contribute between 40% and 75%. Both polygenic and monogenic obesity are influenced by genetic predisposition and environmental factors. Monogenic obesity frequently leads to severe obesity from early childhood and, although rare, recent advances have enabled treatment for genetic abnormalities in the leptin-melanocortin pathway. Identifying genetic causes can contribute to treatment, as well as aid in predicting future prognosis and genetic counseling.
Objective
The aim of this study is to identify the genetic causes of pediatric patients with severe obesity in a single institution in Japan and to contribute to future treatment.
Methods
We enrolled 14 pediatric patients with pediatric severe obesity (BMI percentile $\geq$120). Genetic panel testing for monogenic obesity was performed.
Results
The variants identified in unrelated 5 cases included 4 in *GHRL* and 1 in *PCSK1*.
Conclusion
Monogenic obesity is rare, however, in this cohort, variants were identified in 35.7% of children with severe obesity. Identifying genetic variation in obesity-related genes may provide insights into personalized therapeutic approaches, particularly for cases linked to the leptin-melanocortin pathway. A patient with *PCSK1* variant in this cohort may be eligible for treatment with setmelanotide in the future if it becomes covered by insurance in Japan.

JOINT1864
Comparison of metabolic disorders and obesity characteristics by household composition among korean adults: analysis of DINKs, married individuals with children, and unmarried individuals

Chae Won Chung[1]
[1]Chung-Ang University, Department of Internal Medicine, Seoul, South Korea

Objective
In South Korea, increasing stress levels resulting from political turmoil and economic instability have accelerated declines in marriage and childbirth. Assuming that post-COVID restrictions on outdoor activities adversely affected blood glucose and body weight, we evaluated metabolic health among three groups: married individuals with children (MIWC), DINKs (Dual Income, No Kids), and unmarried individuals. To exclude pregnant women, the 40–50-year-old cohort was selected.
Methods
This cross-sectional study analyzed 13,178,582 Korean adults (7,004,014 males and 6,174,568 females) aged 40–59 who participated in the Korean National Health and Nutrition Examination Survey (2020–2021). Prediabetes or diabetes was identified based on HbA1c levels, hospital diagnoses, or prescriptions for insulin or oral anti-diabetic agents. Obesity was classified into Grade 1 ($25 \leq$ BMI < 30 kg/m^2), Grade 2 ($30 \leq$ BMI < 35 kg/m^2), and Grade 3 (BMI ≥ 35 kg/m^2). A complex sampling design and cross-tabulation analyses were used to examine socioeconomic and laboratory factors.
Results
MIWC represented 72.8% of the sample, DINKs 16.1%, and unmarried individuals 11.1%. In the MIWC group, gender distribution was approximately 51% male and 49% female; in DINKs, 47.8% male and 52.2% female; and in the unmarried group, 75.1% male and 24.9% female. DINK females exhibited a significantly higher prevalence of metabolic disorders compared to MIWC and unmarried females. Specifically, prediabetes was present in 53.4% of DINKs vs 41.1% in MIWC and 24.3% in unmarried females ($P < 0.001$); diabetes in 13.1% vs 7.2% vs 3.7% ($P = 0.005$); dyslipidemia in 31.6% vs 24.0% vs 22.3% ($P = 0.030$); and hypertension in 26.8% vs 16.7% vs 12.8% ($P = 0.001$). Anthropometric and laboratory measurements paralleled these findings, with DINK females showing higher BMI, waist circumference, systolic blood pressure, HbA1c, and fasting glucose compared to unmarried females. Unmarried females had the lowest waist circumference and LDL cholesterol levels. Although male groups did not differ significantly in disease prevalence, unmarried males had higher total cholesterol, triglyceride levels. In addition, Grade 3 obesity was lower in DINKs and higher in MICW compared to unmarried individuals (DINKs: Exp(B)=1.934, 95% CI 0.417, 8.917; MIWC: Exp(B)=0.449, 95% CI 0.068, 2.990; $P = 0.017$).
Conclusion
Our findings indicate that DINK females bear a greater metabolic disorder burden and exhibit more adverse anthropometric and laboratory profiles than MIWC and unmarried females, while unmarried males are at increased risk for dyslipidemia and obesity. These results underscore the importance of considering household composition in metabolic risk assessment and tailoring preventive strategies accordingly.

Medicine, Çanakkale, Türkiye; [12]Ankara Yüksek İhtisas University Faculty of Medicine, Ankara, Türkiye; [13]Health Sciences University Bursa Yİ Education and Research Hospital, Bursa, Türkiye; [14]Marmara University Faculty of Medicine, İstanbul, Türkiye; [15]Fatih Sultan Mehmet Training and Research Hospital, İstanbul, Türkiye; [16]Gulhane Training and Research Hospital, University of Health Sciences, Ankara, Türkiye; [17]Ankara Guven University Hospital, Ankara, Türkiye; [18]Hacettepe University Faculty of Medicine, Ankara, Türkiye; [19]Obesity Canada, Edmonton, Canada

Introduction
Weight bias is common in health care settings, where negative attitudes about overweight patients have been reported by physicians, nurses, and medical students [1-3]. Weight biases present among health professional students are significantly influence students' treatment decisions and beliefs about obesity [4]. In this study, we examined weight bias among medical students in preclinical (1st-2nd-3rd year) and clinical (4th-5th-6th-year) classes, as well as their observations of weight bias among instructors and peers. We then compared the findings across these groups.
Methods
This study utilized a cross-sectional design. A non-randomized sampling was used. Through an online survey, data was conducted among medical students, between January 2023 and July 2023. Three questionnaires previously developed by Puhl *et al*. were utilized [4]. Additionally, the Attitude Towards Obese Persons (ATOP) and Beliefs About Obese Persons (BAOP) scales were used. The scales used in Turkish were previously validated in earlier studies (5).
Results
The survey questions were completed by 1,358 students. Among the participants, 60.4% were female. Of the students who completed the survey, 45.7% ($n = 620$) were from preclinical classes. More than half of the students reported hearing jokes from fellow students about people with obesity. Also clinical students (26.9%) were more than twice as likely as preclinical students (13.2%) to report hearing negative comments or jokes from professors or instructors about people with obesity. ATOP and BAOP scores did not show a statistically significant difference between the preclinical and clinical groups.
Conclusion
These findings suggest that weight stigma is progressively reinforced throughout medical education. Addressing this issue requires systematic educational interventions, including anti-stigma training, curriculum modifications.
Keywords
Weight bias, stigma, medical students

The problem of sarcopenia in patients with obesity undergoing liraglutide therapy
Maria Zhygalina-Hritsenyuk[1]
[1]Ukrainian research institute for medicine of transport, Odesa, Ukraine

Introduction
Sarcopenia, that is characterized by a decrease in muscle mass and strength, is a significant concern for obese patients undergoing treatment with GLP-1 receptor agonists such as liraglutide. While liraglutide has proven to be effective in weight reduction and metabolic improvement, its impact on body composition, particularly lean mass, requires further investigation.
Objective
To assess the impact of liraglutide therapy on muscle mass parameters in obese patients, identify risk factors for sarcopenia, and develop preventive approaches.
Materials and Methods
An observational study was conducted on patients ($n = 110$) with obesity (BMI ≥ 30 kg/m^2) who received liraglutide for ≥ 12 months. The following methods were used:
• Body composition assessment using bioelectrical impedance analysis (BIA)
• Laboratory tests, including serum albumin levels, insulin-like growth factor-1 (IGF-1), total testosterone, and C-reactive protein (CRP) high sensitivity
• Functional diagnostics, handgrip strength assessment.
• Nutritional analysis to identify protein and micronutrient deficiencies.
Results
• A decrease in lean body mass $>10\%$ from baseline was observed in 18% of patients.
• Main identified risk factors for sarcopenia were:
• Low protein intake (≤ 0.8 g/kg body weight);
• Insufficient physical activity (<150 minutes of moderate exercise per week);
• Age over 50 years;
• Insulin resistance and vitamin D deficiency. • In the group with preventive inclusion of physical exercise activity and increased protein intake (≥ 1.2 g/kg), muscle mass reduction was minimal.
Conclusions
1. Liraglutide therapy in obese patients may be associated with the development of sarcopenia, especially in the absence of adequate nutritional support and physical activity.
2. The incorporation of a high-protein diet, resistance training, and nutritional support is crucial for preventing muscle mass loss.
3. Monitoring body composition using DXA or BIA should be an essential part of the comprehensive management of patients receiving GLP-1 receptor agonists.
Practical Significance: A personalized approach considering the nutritional status and physical activity levels can minimize the risks of sarcopenia and enhance the effectiveness of liraglutide therapy, ensuring not only weight loss but also the preservation of patients' functional health.
Keywords
sarcopenia, liraglutide, obesity, muscle mass loss, GLP-1, nutritional support.

What is the minimum dose of vitamin B 12 required to correct the deficiency during long -term metformin use?
Kamila Kendjayeva[1,2], Anna Alieva[1] & Feruza Khaydarova[2]
[1]Republican Specialized Scientific-and-Practical Medical Centre of Endocrinology, Clinics, Tashkent, Uzbekistan; [2]Republican Specialized Scientific-and-Practical Medical Centre of Endocrinology, Tashkent, Uzbekistan

Background
Vitamin B12 deficiency, which inevitably occurs during lifelong metformin therapy in patients with type 2 diabetes, requires timely and adequate vitamin replacement. Moreover, vitamin B12 deficiency mimics the symptoms of diabetic polyneuropathy. However, there are no clear recommendations on the dose and duration of vitamin B12 intake in such patients.
Materials and methods
We conducted a comparative study among 28 patients with type 2 diabetes mellitus with clinical manifestations of diabetic neuropathy. The average age of patients was 60.7 ± 10.0 years, the average duration of diabetes was 7.2 ± 5.4 years, the duration of Metformin intake was 5.5 ± 4.7 years, the average dose of Metformin was 1466.7 ± 544.9 mg, vitamin B12 deficiency was detected in 100% of patients (vitamin B12 level below 197 pg/ml, average level 103.0 ± 19.3 pg/ml). All patients were prescribed vitamin B12. 20 patients took the vitamin in a total course dose below 150 g (up to 1500 mg per day for 3 months). 8 patients received a total course dose above 150 g (maximum 190 g). NSS and NDSS, as well as vitamin B12 levels, were assessed 6 months after the treatment.
Results
Of the symptoms of the NSS and NDSS, a significant difference after treatment was obtained only for the criterion of "burning sensation" (1.46 ± 0.19 points vs 0.88 ± 0.13 points, $P = 0.022$) between the groups; a significantly greater reduction in paresthesia was noted in the group of patients who received a higher course dose of vitamin B12 (87.5% vs 15.0%, $P = 0.005$). No significant difference was found between the groups in terms of other symptoms of peripheral neuropathy.
Conclusion
To reduce neuropathic symptoms associated with vitamin B12 deficiency in patients with type 2 diabetes mellitus receiving long-term metformin, vitamin B12 supplementation at a dose of at least 150 g per course of therapy is necessary.

Hypoglycaemia in non-diabetic children – data from a paediatric endocrine center

Sonya Galcheva[1], Mila Vasileva[1], Polina Pavlova[1] & Violeta Iotova[1]
[1]Medical University of Varna, Department of Paediatrics, Varna, Bulgaria

Objectives
Hypoglycaemia is a metabolic disorder which may be related to a heterogeneous group of disease in non-diabetic patients. The aim of the current study was to establish the frequency of hypoglycaemia observed in non-diabetic children aged 0-18 years, admitted to a tertiary paediatric endocrine center outside the intensive care or emergency unit and to analyze the associated clinical symptoms, underlying causes and treatment strategies.
Methods
We analyzed data for 2 years (2023-2024) from the clinical database of a tertiary paediatric endocrine center to identify all non-diabetic hypoglycaemic patients with blood glucose levels (BGLs) $\leq$3.9 mmol/l. The clinical notes of all enrolled patients were reviewed for demographic data, risk factors for hypoglycaemia, associated clinical symptoms including neurological symptoms and/or seizures during the hypoglycaemic episodes, registered developmental delay, relevant recorded morbidities or newly diagnosed conditions. We performed auxology and standard clinical examination of all participants. Blood glucose levels (BGLs), insulin and other hormones were measured and treatment with intravenous glucose administration and/or specific medications was evaluated. All patients with diabetes or prescribed diabetic medications were excluded from the analysis.
Results
We found 100 hypoglycaemic episodes among 3012 hospital admissions (3.32%). The mean age of the identified patients was 7.6 $\pm$ 5.3 years (ranged 0-17.9 years), 56.0% were boys. The mean BGL during the registered episodes was 3.49 $\pm$ 0.42 mmol/l (1.39-3.90 mmol/l) and the most commonly associated clinical symptoms were fatigue (15%), hypotony (14%), abdominal pain (6%), generalized seizures (3%) and vomiting (3%). Hypoglycaemia due to a newly diagnosed condition was recorded for 34.0% of children, while the other 66 patients had previously recorded disease which could explain the symptoms of low BGLs. Less than 1/3 of the participants had neurodevelopmental delay and 40% of these neurologically affected patients had been diagnosed with epilepsy or cerebral palsy. The most common morbidities associated with the development of hypoglycaemia were: fasting/starvation due to illness/anorexia (31.4%), genetic syndromes (16.2%), hypopituitarism with combined pituitary hormone or isolated growth hormone deficiency (14.1%) and congenital hyperinsulinism (12.1%). One-fifth of children needed glucose infusions to treat hypoglycaemia with none requiring glucagon administration. Almost 60% of the identified participants were commenced or continued on a specific therapy including rhGH (42.4%), long-acting somatostatin analog (13.6%), therapeutic diet/milk (11.9%) and diazoxide (8.5%).
Conclusion
Non-diabetic hypoglycaemia in paediatric patients is of a significant clinical importance and should be diagnosed and treated promptly.

Ketogenic diet fails to counteract western diet-induced damage in skeletal muscle

Alessandro Antonioli[1], Alessia Provera[1], Simone Reano[1], Tommaso Raiteri[2], Sabrina TIni[1], Nicoletta Filigheddu[1,3], Salvatore Sutti[1] & Flavia Prodam[1,4]
[1]University of Piemonte Orientale, Novara, Italy; [2]University of Perugia, Perugia, Italy; [3]University of Piemonte Orientale, Translational Medicine, Novara, Italy; [4]AOU Maggiore della Carità Hospital, SCDU Endocrinology, Novara, Italy.

The Western diet (WD), marked by elevated levels of sugars and saturated fats, significantly contributes to obesity and its related health complications. Its influence on insulin resistance and inflammation has been associated with several conditions, such as type 2 diabetes mellitus (T2DM), metabolic-associated steatotic liver disease (MASLD), and metabolic syndromes (MetS). Ketogenic diets (KDs) represent dietary approaches characterized by minimal carbohydrate intake, high fat, and adequate protein levels. Energy is sourced from ketone bodies (KBs), derived from fat oxidation and protein metabolism. Given the increasing evidence supporting the effectiveness of KDs in reducing inflammation, oxidative stress, and improving mitochondrial function, we hypothesized that KDs could hold promise in addressing obesity-related conditions, including sarcobesity. To test this hypothesis, we subjected mice to a Western diet (WD) for 16 weeks, followed by a transition to an *ad libitum* KD, or continued adherence to WD for an additional 4 or 8 weeks. Our finding demonstrated that within the muscle, a period in KD after WD is sufficient to influence the expression of genes associated with atrophy, autophagy and mitophagy. By exploring mechanisms implicated in muscle loss, we observed that KD leads to a significant reduction in branched-chain amino acids (BCAAs), whose levels are notably elevated in mice fed with WD, that apart their association with inflammation, could be used as primary source to produce ketone bodies in the liver. Finally, to further investigate the impact of fatty acids and KBs on muscle cells, we mimic *in vitro* WD and KD examining various doses of palmitate (PA) and butyrate (BU) on C2C12-derived myotubes. PA significantly reduced myotube diameter in a dose-dependent manner but also induces ROS production, and mitochondrial membrane depolarization. In contrast, low doses of BU protected against PA-induced atrophy in myotubes, while high doses appear to be ineffective or may even contribute to atrophy. Our findings suggest that KD could be detrimental on the muscle. Studies on tailored doses of ketone bodies are needed to understand if they really improve muscle performances.

Body mass index and nutrition-related risk among older people

Justyna Nowak[1], Marzena Jabczyk[2], Michał Skrzypek[3], Bartosz Hudzik[1,4] & Barbara Zubelewicz-Szkodzińska[2,5]
[1]Department of Cardiovascular Disease Prevention, Department of Metabolic Disease Prevention, Faculty of Public Health in Bytom, Medical University of Silesia, Bytom, Poland, Bytom, Poland; [2]Department of Nutrition-Related Disease Prevention, Department of Metabolic Disease Prevention, Faculty of Public Health in Bytom, Medical University of Silesia, Bytom, Poland, Bytom, Poland; [3]Department of Biostatistics, Faculty of Public Health in Bytom, Medical University of Silesia, Bytom, Poland, Bytom, Poland; [4]Third Department of Cardiology, Silesian Center for Heart Disease, Faculty of Medical Sciences in Zabrze, Medical University of Silesia, Zabrze, Poland, Zabrze, Poland; [5]Department of Endocrinology, District Hospital, Piekary Slaskie, Poland, Piekary Slaskie, Poland.

Introduction
BMI is a widely used indicator for assessing body weight in relation to height, commonly applied to evaluate the nutritional status of populations. The GNRI, a nutrition-related risk index, is specifically designed to identify elderly patients at risk of malnutrition-related complications and mortality.
Aim
This study aimed to compare BMI distributions based on the classification ranges defined by the World Health Organization (WHO) and the Committee on Diet and Health (CDH) and to evaluate their correlation with nutrition-related risk assessed through the Geriatric Nutritional Risk Index (GNRI) in older adults.
Material and Methods
The study included 185 patients hospitalized in a geriatric ward. Weight and height measurements were taken in the morning on the first day of admission for all participants using standardized methods and a validated scale. The Geriatric Nutritional Risk Index (GNRI) was calculated to evaluate nutrition-related risk. The study group was divided into two groups: no nutrition-related risk group (GNRI $>$ 98.0) and nutrition-related risk group (GNRI $\leq$ 98.0).
Results
137 individuals (74.1%) were categorized as having no nutrition-related risk. In the No Nutrition-Related Risk Group, the median BMI was 28.5 kg/m^2 (26.4-31.9 kg/m^2). In contrast, the Nutrition-Related Risk Group had a significantly ($P <$ 0.0001) lower median BMI of 22.8 kg/m^2 (20.7-24 kg/m^2). According to the CDH BMI criteria, 75.0% of participants classified as underweight were identified as having a nutrition-related risk, compared to only 6.3% under the WHO BMI criteria. Among patients with normal weight based on WHO criteria, 81.3% were classified as being at nutrition-related risk, whereas this applied to only 22.9% of those with normal weight under CDH criteria. In the excess body weight group, 12.5% diagnosed using WHO BMI criteria were found to be at nutrition-related risk, compared to just 2.1% when using CDH criteria.
Conclusion
This study highlights notable differences between the BMI classification systems recommended by the World Health Organization (WHO) and the Committee on Diet and Health (CDH) when applied to the elderly population. Consequently, it is crucial to create specific guidelines for this age group, especially for interpreting BMI, to ensure more precise health assessments and enhance care for older adults.

Postnatal overfeeding induces gut microbiota disturbances and impairs liver lipid metabolism through GPR43/FIAF/LPL pathway in the rat model of PCOS

Nataša Veličković[1], Miloš Vratarić[1], Bojana Mićić[1], Ana Teofilović[1], Marina Radovanović[1], Sofija Ignjatović[1], Uroš Gašić[1], Ana Djordjevic[1], Djuro Macut[2] & Danijela Vojnović Milutinović[1]
[1]Institute for Biological Research "Siniša Stanković" - National Institute of the Republic of Serbia, University of Belgrade, Department of Biochemistry, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Faculty of Medicine, Belgrade, Serbia

Background & Aims
In women with polycystic ovary syndrome (PCOS), the incidence of metabolic dysfunction-associated steatotic liver disease (MASLD) is high. The development of PCOS-associated MASLD is accelerated by prepubertal obesity, but the extent to which early-life weight gain exacerbates the metabolic features of PCOS is still under debate. To clarify this, we analyzed the impact of overfeeding in early postnatal period on metabolic features, gut microbiota profile and hepatic lipid metabolism in the rat model of PCOS.
Methods
Wistar rats were divided into 4 groups, in which treatment with 5α-dihydrotestosterone (5α-DHT) was used to mimic hyperandrogenemia, whereas litter size reduction was used to induce early postnatal overfeeding and prepubertal obesity. The composition of the intestinal bacterial community was determined by 16S rDNA sequencing. The level of short chain fatty acids was measured by mass spectrometry. Hematoxylin-eosin-stained sections, Western blots, and qRT-PCR were used to analyze hepatic lipid metabolism.
Results
Only postnatally overfed DHT-treated rats developed prominent obesity and glucose intolerance, which was not associated with altered Firmicutes/Bacteroidetes ratio. Postnatal overfeeding shifted the microbiota composition towards obesity-associated genera, while hyperandrogenemia led to reduced β-diversity and an increased abundance of androgen-regulated genera. Interaction of treatments reduced both α- and β-diversity and decreased the abundance of beneficial butyrate-producing genera Roseburia, Oscillospira, and Ruminococcus and plasma level of butyric acid. This shift in microbiota composition was accompanied by decreased expression of G-protein coupled receptor 43 (GPR43), fasting-induced adipocyte factor (FIAF), and increased expression of lipoprotein lipase (LPL). In accordance with the altered GPR43/FIAF/LPL pathway, increased expression of lipogenic transcription factors was observed in SL-DHT animals, but this did not result in hepatic lipid deposition.
Conclusions
Early postnatal overfeeding is important factor in the development of PCOS-related metabolic features, and it is associated with reduced α- and β-diversity and decreased abundance of beneficial butyrate-producing genera in the PCOS animal model. These changes impaired hepatic lipid metabolism via the GPR43/FIAF/LPL pathway. Although these changes are not associated with hepatic steatosis, they may pave the way for fatty liver disease in the long term.

Maternal obesity and gestational weight gain: impact on childhood obesity - a 12 year retrospective cohort study

Margarida Sobral[1], Bárbara Jesus[1], Mariana Coelho[1], Leonor Rodrigues[1], Alice Monsanto[1], Tânia Carvalho[1], Gustavo Rodrigues[1,2], Ana Sofia Lopes[1], Joana Guiomar[1], Carolina Moreno[1,2] & Leonor Gomes[1,2]
[1]Endocrinology, Diabetes and Metabolism Department - Coimbra's Local Health Unit, Coimbra, Portugal; [2]Faculty of Medicine of the University of Coimbra, Coimbra, Portugal

Introduction
Maternal obesity and excessive gestational weight gain are associated with childhood obesity through various mechanisms. According to international recommendations, weight gain during pregnancy for obese women (BMI ≥ 30 kg/m^2) should not exceed 9 kg. This study aims to analyze the weight evolution of children born to obese mothers and the association between preconception BMI and gestational weight gain with childhood BMI, based on WHO percentile curves.
Methods
This retrospective cohort study included 48 children whose mothers, diagnosed with obesity, were monitored during pregnancy in endocrinology/obstetrics consultations between 2010 and 2011. Maternal anthropometric data were collected during successive consultations, and children's growth data were recorded from birth to 12 years of age.
Results
The 48 women considered, had an average preconception BMI of 37.2 ($\pm$2.24) kg/m^2. A total of 64.6% of the women experienced excessive weight gain (>9 kg) during pregnancy. 12 of these women had been diagnosed with gestational diabetes, but were controlled with dietary measures. The average birth weight was 3,426.4 g ($\pm$388.325), with 22.9% ($n = 11$) classified as large for gestational age (weight above the 90th percentile). At 12 months, 37.5% of the children ($n = 19$) were above the 85th percentile for weight, and 20.8% ($n = 10$) were above the 97th percentile. By 3 years of age, 37.5% ($n = 19$) were classified as obese, and 27.1% ($n = 13$) were overweight. The prevalence of overweight and obesity continued to rise throughout childhood, reaching 66.7% at 6 years ($n = 33$), 83.3% at 10 years ($n = 40$), and 77.2% at 12 years ($n = 37$). Regarding gestational weight gain, a positive correlation was found between excessive maternal weight gain and higher degrees of childhood obesity ($P < 0.05$). Additionally, while higher pre-pregnancy obesity classes showed a trend toward increased childhood obesity, this association did not reach statistical significance ($P > 0.05$).
Conclusion
The prevalence of overweight and obesity in children born to obese mothers tends to increase throughout childhood. Excessive gestational weight gain is positively associated with a higher degree of childhood obesity. This association should encourage health professionals and caregivers the prompt adoption of healthy lifestyle measures in childhood and the implementation of early monitoring and surveillance of this children.

Long-Term and short-term studies on metformin in obese children and adolescents: evaluating metabolic and cardiovascular outcomes

Ashraf Soliman[1], Noor Hamed[1], Anas Abdul kayoum[1], Nada Alaaraj[1], Noora AlHumaidi[1], Shayma Ahmed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Obesity in children and adolescents is a global health challenge linked to metabolic and cardiovascular complications. Metformin, a drug primarily used for type 2 diabetes, has gained attention for its potential benefits in managing obesity-related cardiometabolic risks. This review synthesizes evidence on metformin's short- and long-term effects, including its impact on BMI, insulin sensitivity, inflammation, lipid profiles, and cardiovascular risk markers.
Methods
This review included 19 studies, comprising 10 randomized controlled trials (RCTs), observational studies, systematic reviews, and meta-analyses. Collectively, these studies evaluated 777 patients, with a focus on obese children and adolescents. Key outcomes examined included BMI changes, insulin sensitivity, inflammatory markers, lipid profiles, and vascular health indicators.
Results
This review analyzed 19 studies, including 10 randomized controlled trials (RCTs) with 657 patients, alongside observational studies, systematic reviews, and meta-analyses, encompassing a total of 777 patients. High-quality RCTs, such as those by Yanovski *et al*. (2011), Pastor-Villaescusa *et al*. (2017), and Masarwa *et al*. (2021), demonstrated metformin's consistent efficacy in reducing BMI and improving insulin sensitivity. Short-term studies showed significant improvements, including a **3-5% reduction in BMI**, **15-20% improvement in insulin sensitivity** (**HOMA-IR scores**), and **10-15% reduction in pro-inflammatory markers**. Lipid profile improvements included **5-8% enhancement in HDL and triglyceride ratios**, and cardiovascular markers, such as carotid intimal-medial thickness (CIMT) and blood pressure, showed modest improvements of approximately **5%**. Long-term impacts, while less pronounced, included sustained effects such as a **2-3% reduction in BMI**, **5-10% improvement in insulin sensitivity**, and **2-5% improvements in lipid profiles**. Notably, cardiovascular markers, such as CIMT and blood pressure, demonstrated **~10% sustained improvement** over time. While inflammation data were limited in long-term studies, a sustained effect of **~5% reduction in pro-inflammatory markers** was suggested. The findings highlight metformin's robust short-term effects in managing obesity-related metabolic risks, with evidence supporting its use in insulin-resistant and prepubertal populations. Across all studies, metformin demonstrated a favorable safety profile with no serious adverse events, making it a cost-effective and valuable intervention for pediatric obesity.
Conclusions
Metformin is a safe and effective intervention for short-term management of pediatric obesity and its cardiometabolic risks. Evidence supports its ability to modestly reduce

BMI, improve insulin sensitivity, and address key cardiovascular risk factors. Long-term benefits, particularly in preventing cardiovascular events, require further research. Its consistent safety and cost-effectiveness make metformin a valuable therapeutic option for managing obesity-related metabolic challenges in children and adolescents.

A rare case of hutchinson-gilford progeria syndrome

Nabilah Wairooy[1], Nur Rochmah[2,3], Rayi Kurnia Perwitasari[2,3], Yuni Hisbiyah[2,3] & Muhammad Faizi[2,3]
[1]Faculty of Medicine—Universitas Airlangga, Surabaya, Indonesia; [2]Department of Child Health, Faculty of Medicine—Universitas Airlangga, Surabaya, Indonesia; [3]Department of Child Health, Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Introduction
Progeria or Hutchinson-Gilford Progeria Syndrome (HGPS) is a rare autosomal dominant syndrome that accelerates ageing and affects internal systems, affecting 1 in 18 million people. It is linked to lamin mutations and high hyaluronic acid levels, leading to cardiovascular and sclerodermatous changes. Bioinactive growth hormone and excess hyaluronic acid may stunt growth. While some endocrine aspects are studied, metabolism remains unclear. We report a case highlighting its complications.
Case report
A 12-year-old girl presented with progressively coarse skin, growth failure, and global alopecia. She appeared normal until age 2, when her parents first noticed these changes. Her prenatal history was unremarkable, intelligence average (IQ = 82), and no family history of similar conditions. She exhibited a senile appearance with prominent eyes, visible scalp veins, alopecia, peaked nose, and a small chin. Her hands were short and clawed, with thickened knuckle skin and racquet nails. The trunk and lower limbs showed mottled pigmentation and sclerodermatous changes. Ophthalmologic findings included bilateral lagophthalmos and left eye pterygium. ENT examination was normal. Chest auscultation revealed murmurs. Medical records show the patient weighs 11.5 kg ($<5^{th}$ percentile) and is 105,5 cm tall ($<5^{th}$ percentile), with BMI of 10.3 (Z score <-3). Progeria was diagnosed based on history and clinical findings. She has impaired glucose tolerance (fasting glucose 73 mg/dl, random glucose 136 mg/dl, HbA1c 5.7%), normal renal function, elevated liver enzymes (AST 183 U/l,ALT 187 U/L), and dyslipidemia (TC 207 mg/dl, TG 348 mg/dl, HDL 23 mg/dl, LDL 143 mg/dl). Electrolytes are normal, but blood gas analysis shows a mildly increased pH (7.46). Echocardiogram reveals severe mitral regurgitation, mild atrial regurgitation, severe mitral and atrial stenosis. Nutritional therapy includes 1500 kcal/day, primarily from carbohydrates 1356 kcal/day (90%), with protein 21.2 g/day (1.2 g/kg/day) and fat 900–1210 kcal/day (90–110 kcal/kg/day). Formula milk is administered in 5 servings/220 ml (6 scoops + 180 ml water), alongside three meals containing one egg per meal. Feeding occurs at scheduled intervals. She is prescribed lisinopril (1 mg/day) with echocardiograms every three months. For lagophthalmos, she receives Hyalub (3×1 ODS) and Cenfresh (6×1 ODS), with a two-week follow-up. scheduled. She continues outpatient follow-up in pediatric endocrinology, nutrition, cardiology, and ophthalmology.
Conclusion
Analysing indicators and identifying targetable deficits may offer potential for addressing cardiovascular disease and other significant phenotypes in HGPS, which have thus far been inadequately associated with these recognised endocrine changes.

Obesity-related metabolic dysfunction-associated steatotic liver disease: clinical characteristics and risk factors in children

Yu Yang[1], Hui Huang[1], Li Yang[1], Liling Xie[1] & Dong-guang Zhang[1]
[1]Jiangxi Provincial Children's Hospital, Nanchang, China

Background
Non-alcoholic fatty liver disease (NAFLD), now recognized as metabolic dysfunction-associated steatotic liver disease (MAFLD), is closely linked to obesity and its metabolic complications in adolescents. This cross-sectional study aims to assess the prevalence and characteristics of MAFLD in obese children and adolescents, examining the relationship between obesity, metabolic dysfunction, and liver health.
Methods
We retrospectively reviewed the clinical data of 487 obese children aged 7-14 years from the Department of Endocrine Genetic Metabolism at Jiangxi Children's Hospital between January 2020 and December 2022. Inclusion criteria were based on age and waist height ratio (WHtR), while exclusion criteria ruled out genetic obesity, diabetes mellitus, and other secondary causes of obesity. Clinical data included medical history, physical examination, laboratory tests, and insulin resistance assessment. The diagnosis of MAFLD was based on the presence of hepatic steatosis and at least one cardiometabolic risk criterion.
Results
The study cohort consisted of 479 children, with a median age of 10.6 years. The prevalence of MAFLD increased with age, affecting 45% of 7-9-year-olds and 68% of 10-14-year-olds. Males were more commonly affected, with a male-to-female ratio of 3.3:1. The MAFLD group had a higher average BMI, height, and weight compared to the non-MAFLD group. Liver enzymes were significantly elevated in the MAFLD group, indicating liver damage. The MAFLD group also exhibited higher insulin resistance, dyslipidemia, and lower kidney function. The binary logistic regression model identified alanine aminotransferase (ALT) and gamma-glutamyl transferase (GGT) as significant positive predictors of MAFLD, while high-density lipoprotein (HDL) was a significant negative predictor.
Conclusion
MAFLD is prevalent in obese adolescents and is associated with insulin resistance, dyslipidemia, and liver dysfunction. The study highlights the importance of early identification and management of MAFLD in obese pediatric populations to prevent long-term complications.
Keywords
Metabolic dysfunction-associated steatotic liver disease (MAFLD), Adolescents, Obesity, Insulin resistance, Dyslipidemia, Liver enzymes.

Impact of family physicians' practice location and sector on the management of childhood obesity

Mouna Elleuch[1], Hamdi Frikha[1], Fatma Lachtar[1], Zaineb Fourati[1], Yassmine Abdelkafi[1], Yosra Majdoub[2], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Preventive & Community Medicine, Sfax, Tunisia

Introduction
Childhood obesity (CO) is a major public health concern, requiring early and appropriate management. As frontline healthcare providers, family physicians (FPs) play a crucial role in the screening, diagnosis, and treatment of this condition. However, their practices may be influenced by their location and sector of practice, potentially leading to disparities in care quality. This study aims to analyze these differences to identify potential areas for improvement and ensure more standardized and effective management of CO.
Methods
We conducted a cross-sectional descriptive and analytical study using a questionnaire assessing the practices of frontline FPs working in southern Tunisia. Data collection was carried out online or through direct interviews during 2024. Three main areas were evaluated: screening, diagnosis, and treatment of CO. Statistical analysis was performed using SPSS software.
Results
A total of 100 FPs participated, with a mean age of 48±11 years and a female predominance (64%). The majority worked in the public sector (59%) and urban areas (52%). Urban practice was associated with better screening practices (anthropometric assessment performed in 83% of cases, $P = 0.017$) and more thorough etiological investigations ($P = 0.03$). Dietary and pharmacological management approaches were similar, except for more personalized dietary counseling in urban settings ($P = 0.03$). Private-sector practice was significantly associated with better anthropometric and dietary assessment of CO patients ($P < 0.001$ and $P = 0.03$) and a more individualized management approach ($P = 0.04$). However, etiological assessment, evaluation of complications, and referral rates to specialist centers were comparable across groups.
Conclusion
Disparities in medical practice quality appear to be widening, particularly in favor of urban areas and the private sector. Our findings highlight more effective CO management in these settings, likely due to better financial resources, easier access to scientific training, greater proximity to specialized centers, and a reduced workload. Strengthening healthcare structures in rural areas and the public sector is essential to ensure equitable CO management.

JOINT1712

Recurrent non-islet cell tumor hypoglycemia secondary to a large pulmonary tumor

Ibtissem Oueslati[1], Nezha Hafsi[1], Helena Mosbah[1], Florence Torremocha[1], Mathilde Fraty[1] & Xavier Piguel[1]
[1]University Hospital of Poitiers, Department of Endocrinology, Poitiers, France

Introduction
Hypoglycemia in non-diabetic patients is a rare metabolic emergency that can arise from various causes. Non-islet cell tumor hypoglycemia is a rare but serious cause of hypoglycemia characterized by a paraneoplastic syndrome caused by a tumor that secretes high molecular weight IGF-2. Herein, we report a case of severe recurrent non-islet cell tumor hypoglycemia secondary to a large pulmonary tumor.
Observation
A 91-year-old woman was referred to the Endocrinology Department for hypoglycemia. Her medical history included hypertension, dyslipidemia, thyroid nodule, and a non-functional adrenal adenoma. In 2016, she presented with severe hypoglycemia and dyspnea. Laboratory investigations revealed low insulin and C-peptide levels during the hypoglycemic event. Although IGF1 and IGF2 levels were normal, the IGF2/IGF1 ratio was greater than 10, raising suspicion of a non-islet cell tumor secreting IGF2. A chest computed tomography (CT) scan showed a large right lung tumor measuring 150 mm. A PET-scan showed no significant hypermetabolism in the lung mass. The patient was treated with corticosteroids and subsequently underwent a right pulmonary lobectomy. Anatomopathological examination revealed a benign fibrous tumor. Long-term follow-up was marked by the resolution of hypoglycemia. Eight years later, the patient presented with recurrent severe hypoglycemia, asthenia, and weight loss. On physical examination, she had a good state of hydration, a body weight of 44.2 kg, a height of 147 cm, a body mass index of 20.45 kg/m^2, a blood pressure of 128/59 mmHg, a heart rate of 69 beats per minute. Biological investigations showed a fasting blood glucose level of 0.36 g/l,an insulin level of less than 7 nmol/l,a C-peptide level of 0.03 nmol/l,an IGF1 level of 27 ng/ml, an IGF2 level of 485 ng/ml, and an IGF2/IGF1 ratio of 18. The CT scan revealed a necrotic and heterogeneous lung parenchymal mass measuring 111 mm in the right upper lobe. The patient was treated with corticosteroids and referred to the department of Thoracic Surgery.
Discussion
In this case, hypoglycemia was secondary to a fibrous pulmonary tumor that secretes IGF-2. IGF-2 interacts with insulin receptors, leading to the inhibition of gluconeogenesis, glycogenolysis, and ketogenesis. Generally, the diagnosis of non-islet cell tumor hypoglycemia is suggested when low insulin and C-peptide levels are observed during a hypoglycemic episode, along with a high IGF2/IGF1 ratio (>3). Most fibrous tumors are benign. However, late tumor recurrence with aggressive features has been reported, even in the absence of prior evidence of malignancy.

Obesity associated with macroprolactinoma: a case report

Nayla Hanane Essaidi[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohammed VI University Hospital of Marrakech, Marrakech, Morocco

Introduction
Prolactin-secreting pituitary adenomas (prolactinoma) are generally benign tumors that appear following the monoclonal expansion of a cell line of the anterior pituitary (lactotropic cells). Prolactin (Prl) is a polypeptide hormone, primarily regulated by the inhibitory control of dopamine. This suppression has been proposed as a potential mechanism responsible for weight gain and metabolic abnormalities in patients. Elevated prolactin may promote obesity by disrupting lipid metabolism and influencing appetite. Prolactinomas are classified based on their size into microprolactinomas (<10 mm largest diameter) and macroprolactinomas (≥ 10 mm largest diameter) Treatment is primarily based on dopamine agonists, particularly cabergoline.
Case report
A 9 years old patient, diagnosed with a giant macroprolactinoma, who underwent surgery and experienced post-operative corticotropic deficiency, for which replacement therapy was started at a dose of 10 mg per day. The patient's progression was marked by significant weight gain associated with polyphagia, and the case is being closely monitored as part of our clinical care protocol On clinical examination, the patient had a BMI of 30 kg/m^2 and a waist circumference of 95 cm, which were indicative of pathological obesity.
Discussion
Hyperprolactinemia induces a functional blockade of dopaminergic tone, which may contribute to hyperphagia and weight gain observed in patients, thus playing a role in the pathogenesis of obesity, as demonstrated in our patient Expression of the Prl receptor (Prl-R) gene has previously been described in adipose tissue, and an increase in this expression during lactation has been documented in rats and humans. the study by Haji H *et al* demonstrated in Prl-R-deficient mice a reduction in abdominal fat and leptin concentration compared to controls. Studies have clearly shown that dopamine agonists significantly improve glucose homeostasis and insulin resistance and reduce body weight.
Conclusion
Hyperprolactinemia (HPL) promotes metabolic alterations, and controlling excess prolactin with dopamine agonists is essential for inducing weight loss and improving the metabolic profile.

Assessing body composition in individuals with obesity

Salma El Hilali[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]University Hospital Center Mohammed VI, Department of Endocrinology and Metabolic Diseases, Marrakesh, Morocco

Introduction
Obesity is now recognized as a global pandemic and a major public health problem. It is characterized by an excessive accumulation of body fat, often associated with metabolic, cardiovascular and musculoskeletal complications. Beyond body mass index (BMI), which remains the most commonly used diagnostic tool, detailed assessment of body composition provides a better understanding of the imbalances between the various body compartments (fat, muscle, bone, water).
Methods
This is a retrospective observational study of patients living with obesity and hospitalized in the Endocrinology and Metabolic Diseases Department of the Mohammed VI University Hospital of Marrakesh. Data were collected from medical records. Body composition assessment was performed by an analyzer using bioelectrical impedanceanalysis (BIA) technology.
Results
Over two years, 70 patients were hospitalized in our center and benefited from impedance analysis. Their mean age was 46.9 ± 14.6 years (14-77 years), with a large female predominance (94.3%). The mean BMI in our series was 45.3 ± 6.9 kg/m^2 (30.1-60.5 Kg/m^2). Moderate obesity (BMI:30.0-34.9 kg/m^2) was found in 21.4% of patients; severe obesity (BMI:35.0-39.9 kg/m^2) in 37.1%; and morbid obesity (BMI>40 kg/m^2) was noted in 41.4%. The mean percentage of body fat mass was 43.8 ± 6.9%. The mean percentages of lean body mass and body muscle mass were 57 ± 6.3% and 52.5 ± 7% respectively. Mean percentages of total body water and bone mass were 41.1 ± 3.8% and 2.8 ± 0.3% respectively. The mean basal metabolic rate was 1711 ± 230.2 Kcal/day and the mean metabolic age was 61 ± 12.8 years. Forty-nine patients had a glucose metabolism disorder, i.e. 70% of our series, of whom 47.1% had diabetes and 22.9% pre-diabetes. Fourteen patients had a lipid metabolism disorder, i.e. 20% of our series, of whom 15.7% had pure hypercholesterolemia, 2.9% hypertriglyceridemia and 1.4% mixed dyslipidemia. Twenty two patients had arterial hypertension, i.e. 31.4% of our series. In our study, linear regression analysis showed that the increase in fat mass percentage correlated statistically significantly with the increase in BMI (P value < 0.001) and the decrease in muscle mass (P value $= 0.003$). On the other hand, we found no significant association between BMI or fat mass percentage with the presence of a glucolipid metabolic disorder or hypertension.
Conclusion
Individuals with obesity do not have the same body composition profile nor the same metabolic risks. A detailed analysis of these parameters would not only help to characterize obesity (type and metabolic status), but also to guide therapeutic strategies for tailored and personalized management.

JOINT3301

Baseline morphofunctional characteristics of a sample of transgender individuals from a specialized transgender healthcare unit

Juan Luis Delgado Montoya[1], Javier García Sánchez[1], María Teresa Zarco Martín[1], Maria Dolores Aviles Perez[1], María Luisa Fernández Soto[1] & Pablo J López- Ibarra Lozano[1]
[1]Hospital Universitario Clínico San Cecilio, Granada, Spain

Introduction and Objective
Individuals experiencing gender incongruence with their sex assigned at birth may seek gender-affirming hormone therapy (GAHT) to align their gender

expression with their identity. GAHT is known to induce changes in body composition, and advanced morphofunctional assessment techniques could serve as valuable tools for evaluating these modifications. This study aims to analyze the morphofunctional characteristics of this population before the initiation of hormone therapy.
Materials and Methods
A descriptive observational study was conducted on individuals aged ≥18 years seeking GAHT at the Transgender Healthcare Unit (UAPT) of Hospital Universitario Clínico San Cecilio in Granada. Anthropometric variables, muscle strength (handgrip dynamometry), bioelectrical impedance parameters—including metabolically active cellular mass (BCM) and total body water (TBW)—as well as muscle and abdominal ultrasound measurements, were assessed.
Results
The study included 14 trans men and 7 trans women, with mean ages of 20.93 ± 3.36 and 22.85 ± 4.8 years, respectively, and BMI values of 23.83 ± 7.38 kg/m^2 vs. 22.51 ± 6.11 kg/m^2. Handgrip strength was higher in trans women (26.57 ± 10.32 kg vs. 25.02 ± 7.13 kg; $P > 0.05$). This finding aligns with a trend toward statistical significance in Y-axis thickness (1.79 ± 0.53 cm vs. 1.41 ± 0.32 cm, $P = 0.054$) and rectus femoris muscle area (5.87 ± 2.53 cm^2 vs. 3.84 ± 1.03 cm^2), as measured by ultrasound. These parameters correlate with total muscle mass and strength. Statistically significant differences were observed in BCM (x?;: 32.87 ± 7.34 kg/m^2 vs. 24.03 ± 4.28 kg/m^2, $P < 0.05$) and TBW (x?;: 43.62 ± 9.9 kg/m^2 vs. 31.38 ± 4.03 kg/m^2, $P < 0.05$), both higher in trans women. No significant differences were found in abdominal ultrasound measurements of superficial adipose tissue (0.57 ± 0.39 cm vs. 0.52 ± 0.45 cm, $P = 0.807$) or preperitoneal adipose tissue (0.57 ± 0.48 cm vs. 0.55 ± 0.29 cm, $P = 0.868$).
Conclusions
This study provides novel insights into the application of advanced morphofunctional assessment techniques for characterizing body composition and muscle strength changes in transgender individuals before GAHT. These findings establish a baseline for future research into the physiological effects of hormone therapy.

Efficacy on nutritional status of a nutritional support programme with specific supplementation for people with type 2 diabetes at risk of malnutrition in routine clinical practice

Ana María Moyano-Sánchez[1], Pilar Pérez Reyes[1], Aura Dulcinea Martínez Herrera[1], María Ángeles Gálvez Moreno[1] & María José Molina Puerta[1]
[1]UGC Endocrinología y Nutrición. Hospital Universitario Reina Sofía, Department of Endocrinology and nutrition, Córdoba, Spain

Introduction and Objectives
Diabetes mellitus is a highly prevalent disease that can affect nutritional status as well as muscle mass and function. This study aims to evaluate the differences in nutritional status, through the analysis of morphofunctional and biochemical assessment parameters, of patients with diabetes and disease-related malnutrition (DRE) or high nutritional risk, at baseline and three months after starting specific nutritional supplementation.
Material and Methods
We selected 15 patients assessed in nutritional prehabilitation consultations, with a diagnosis of type 2 diabetes mellitus and digestive cancer, with DRE or high nutritional risk according to GLIM criteria, undergoing active cancer treatment (chemotherapy, surgery). A nutritional support programme was initiated with dietary recommendations, exercise and specific supplementation for people with type 2 diabetes. Anthropometric, biochemical and morphofunctional assessments were performed using vector bioimpedance (BIVA), at the first consultation and at a 3-month review. Differences were analysed using SSPS v.24 statistical software. A value of $P < 0.05$ was considered statistically significant and trend to statistical significance $P < 0.1$.
Results
Mean age 71.3 years (SDS 8.2). Three months after the start of nutritional supplementation, all morphofunctional parameters measured by BIVA (FFM, FFMI, FM, FMI, SM, SMI, SMI, ASM, ASMI) had increased. In particular, weight (69 vs 71kg; $P < 0.1$), BMI (26.5 vs 27.2 kg/m^2; $P < 0.1$) and appendicular skeletal mass (ASM) (17.8 vs 18.3 kg; $P < 0.1$) had improved with a trend towards statistical significance. At the biochemical level, three months after the start of nutritional supplementation (baseline vs 3 months): - Vitamin D (12.5 vs 29.7; $P < 0.05$), folic acid (13.8 vs 15.8; $P < 0.1$), albumin (4.19 vs 4.27; NS), pre-albumin (21.9 vs 24.1; NS) and glomerular filtration rate (78 vs 86; $P < 0.1$) levels improved. - Inflammation markers leucocytes (7909 vs 6298; $P < 0.1$), PCR (44.3 vs 22.7; NS) and ferritin (299 vs 206, $P < 0.036$), decreased. Glycaemic control showed no variation (HbA1c 6.5% vs 6.36%; NS), (haemoglobin 12.1 vs 12.4; NS).
Conclusions
The implementation of a nutritional support programme in routine medical practice, based on dietary recommendations, exercise and specific supplementation for people with type 2 diabetes with malnutrition or high nutritional risk, improved morphofunctional and biochemical outcomes in our cohort of oncology patients.

JOINT1889

Evaluation of muscle strength in patients with type 1 diabetes mellitus: comparison of reference values

Javier Gómez Pino[1], Luis Ignacio Navas Vela[1], Viyey Kishore Doulatram Gamgaram[1], Mariana Gomes Porras[1,2] & Gabriel Olveira Fuster[1]
[1]Regional University Hospital of Malaga, Endocrinology and Nutrition, Málaga, Spain; [2]PhD student at the University of Malaga., Málaga, Spain

Introduction
Handgrip strength is a widely used method to evaluate muscle strength, a key component of physical fitness. It is well known that low muscle strength is significantly related to early mortality from all causes and cardiovascular disease, as well as greater physical disability.
Objective
To compare the results obtained in the dynamometry of patients with type 1 diabetes mellitus followed at the Hospital de la Axarquía with different reference values (international, European Sarcopenia Consensus values, and reference values from a local study conducted in Pizarra).
Material and Methods
Descriptive cross-sectional observational study in patients with type 1 diabetes mellitus followed at the Hospital de la Axarquía. Clinical data were obtained from the medical history, and dynamometry data were obtained with a Jamar dynamometer. Statistical analysis was performed with the Jamovi program. A low dynamometry value was defined as.
Results
The sample of our study consisted of 134 patients, of which 78 were men (58.2%) and 56 were women (41.8%). The mean age was 45.6 years (±14.4) and the mean BMI was 26.4 kg/m^2 (±5.01). The mean duration of diabetes was 22.4 years (± 13.7 years) and the mean HbA1c was 7.75% (±1.06%). The mean dynamometry value was 41.2 kg (±10.4) in men and 24.9 kg (±6.29) in women. In men, a low dynamometry value was obtained in 7 (9%; with respect to international values), 13 (16.9%; with respect to values from the Pizarra study) or 4 (5.1%; with respect to dynapenia values of the European Consensus). In women, a low dynamometry value was obtained in 8 (14.3%; with respect to international values), 5 (9.1%; with respect to values from the Pizarra study) or 4 (7.1%; with respect to dynapenia values of the European Consensus).
Conclusions
The comparison between the three reference points (international, European Consensus, and Pizarra) reveals differences in the proportion of patients identified with low muscle strength. These differences highlight the importance of choosing appropriate reference points according to the population context.

Comparative analysis of morphofunctional parameters and clinical results in post-critical patients based on the definition of obesity used: body mass index or fat mass percentage

Víctor Simón-Frapolli[1], Víctor Siles-Guerrero[2], Jose Manuel Garcia-Almeida[1] & Francisco José Tinahones Madueño[1]
[1]Hospital Virgen de la Victoria, Malaga, Spain; [2]Hospital Virgen de las Nieves, Granada, Spain

Introduction
Obesity in adults is commonly classified using BMI, with values over 30 kg/m^2 indicating obesity. However, BMI has limitations as it doesn't accurately reflect body composition. Fat mass percentage (FM%) is a more precise measure, and can be estimated using various methods, with bioimpedancemetry being a cost-effective, accurate, and radiation-free option. According to the Consensus Statement of the European Society for Clinical Nutrition and Metabolism and the

European Association for the Study of Obesity (ESPEN and EASO) on sarcopenic obesity, obesity is defined as a body fat percentage (FM%) higher than 30% in men and 40% in women, respectively.

Objective

To compare body composition, complications, and need for aggressive therapies in post-critical obese patients, using two definitions of obesity: FM% > 30% in men and > 40% in women, vs BMI > 30 kg/m^2.

Methods

Prospective observational study including 75 patients admitted to the ICU for severe COVID-19 pneumonia. Demographic, clinical and analytical data were collected during admission, medical history and a complete morphofunctional assessment was performed 14 days after hospital discharge with bioimpedancemetry and phase angle, nutritional ultrasound, dynamometry and functional tests. Two mutually exclusive groups were established, one defined as BMI > 30kg/m^2 and the other as high FM% with normal BMI, and the differences between them were analyzed.

Results

Table 1.

	All	BM>30 kg/m^2	FM>30% (men); FM>40% (women)	p (t student)
	n = 75	*n* = 36	*n* = 10	
BMI(kg/m^2)	31.1±6.4	36.1±5.6	26.4±5.6	<0.001*
Diabetes mellitus(%)	34(45.3)	4(11.1)	6(60.0)	0.003*
PhA(º)	4.9±1.12	5.2±1.2	4.3±1.2	0.029*
SPhA	-1.00(1.1)	-0.45±0.9	-2.2±0.9	<0.001*
FFM(kg)	59.9±11.7	65.7±11.7	50.8±11.7	<0.001*
FM(kg)	30.6±13.4	39.2±13.9	27.7±13.9	0.010*
ASMM(kg)	23.6±5.9	26.8±6.0	19.3±6.0	<0.001*
SMI(cm^2/m^2)	9.84±1.8	10.8±1.7	7.9±1.7	<0.001*
BCM(kg)	28.9±8.6	32.4±9.0	22.1±4.0	0.001*
RF-CSA(cm^2)	4.21±1.5	4.8±1.7	3.0±1.7	0.011*
RF-Y axis(cm)	1.32±0.4	1.6±0.4	1.0±0.4	<0.001*
CRP	26.9±50.1	17.5±29.7	81.8±21.7	0.046*
HGS(kg)	24.7±12-3	28.6±13.1	18.8±13.1	0.021*
Hospital stay(-days)	48.3±44.9	41.6±20.1	73.8±71.0	0.037*

.

Conclusions

Patients with BMI < 30 kg/m^2 but with FM > 30% (men) or > 40% (women) have differences in body composition parameters (BIA, nutritional ultrasound and dynamometry) and are also associated with a higher prevalence of diabetes mellitus and worse clinical outcomes during admission (longer hospital stay). In terms of body composition, there are differences especially in parameters related to muscle mass, but also in proinflammatory parameters.

Dietary factors contributing to overweight and obesity in children

Mouna Elleuch[1], Yesmine Elloumi[2], Omaima Dimassi[2], Ines Ketata[3], Mouna Aboub[4], Faten Hadj Kacem[2], Nadia Charfi[2], Mouna Mnif[2], Dhoha Ben Salah[4] & Nabila Mejdoub Rekik[1]

[1]Hedi Chaker University Hospital, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia; [3]Ben Arous Hospital, Tunis, Tunisia; [4]Bir Ali Hospital, Bir Ali, Tunisia

Background

Childhood obesity and overweight have become pressing global health concerns, affecting an increasing number of children. These conditions have significant consequences on both physical and mental well-being, making them a crucial issue for society. Among the many contributing factors, dietary habits play a key role. This study aims to explore the dietary influences that contribute to childhood obesity and overweight.

Methods

This was a case-control cross-sectional study, conducted over a year in 2022, included 216 children from school health clinics in Tunis, Tunisia, excluding those with secondary obesity causes. Overweight was defined as a BMI > 1 standard deviation (SD) above the median of WHO growth standards, and obesity as a BMI > 2 SDs above the median. The children were categorized into groups: G1 of 54 overweight or obese children and G2 of 162 of normal weight children. We administred a questionnaire to children and their parents to evaluate the dietary risk factors of obesity.

Results

No significant association was found between overweight or obesity and age (P = 0.07), but the prevalence was significantly higher in male children (P = 0.038). No significant correlation was found between biscuit consumption and overweight or obesity in children (P = 0.72). However, the consumption of Cerelac was statistically associated with the presence of overweight or obesity (P = 0.03). A diet rich in fruits was more common in G1 (P = 0.62). G1 children had a lower fiber intake though this difference was not statistically significant (P = 0.72). Carbohydrate-rich diets were significantly more frequent among overweight or obese children (P = 0.038). A diet high in plant-derived fats was more common in the overweight or obese group (P = 0.439). No significant link was found between consumption of animal-derived fats and the presence of obesity or overweight (P = 0.254). Similarly, no significant relationship was found between night-time dessert consumption and obesity or overweight (P = 0.126). Snacking was reported by 17.7% of children in the normal weight group compared to 16.7% in the overweight/obese group, with no significant correlation with obesity or overweight (P = 0.867). The independent factors associated with the presence of overweight or obesity in children were male gender, Cerelac consumption, and a high intake of carbohydrates.

Conclusion

Tackling the underlying causes of childhood obesity and overweight, with a focus on understanding and addressing key contributing factors, is essential to reversing this escalating epidemic.

Nutrient intake in overweight patients with polycystic ovary syndrome (PCOS): a comparative study

Kamilia Ounaissa[1], Sana Khamassi[1], Taieb Ach[2], Ramla Mizouri[3], faten mahjoub[3], Emna Bornaz[1], Ben Hamida Yosra[1], Haifa Abdesselem[1], Asma Ben Brahim[1], Rym Yahyaoui[1], Jamoussi Henda[3] & Chiraz Amrouche[1]

[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]Farhat Hached Hospital, Department of Endocrinology and Diabetology, Sousse, Tunisia; [3]National Institute of Nutrition and Food Technology, UR17SP01-Clinical Biology Laboratory, Tunis, Tunisia

Background

Polycystic Ovary Syndrome (PCOS) is a common endocrine disorder affecting women of reproductive age. The role of macronutrient and micronutrient intake, both in the development of PCOS and in managing its symptoms, is an area of increasing interest [1]. The aim of our study was to evaluate nutrient intake in overweight patients with PCOS.

Methods

This was a descriptive, cross-sectional and retrospective case-control study involving 61 overweight women, divided into two groups: 31 women with PCOS in the case group and 30 women without PCOS in the control group. The two groups were matched for age and body mass index. Data, including interview-based information and biological parameters were collected from the patients' medical records. Body composition was assessed using TANITA bioimpedance analysis. Dietary intake data were analyzed using Nutrisoft software.

Results

The mean age of the patients with PCOS and without PCOS was 31±8.6 years and 34.23±10.6 years, respectively. The mean age at diagnosis of PCOS was 23.4±7.3 years, with extremes ranging from 14 to 39 years. The majority of patients with PCOS had phenotype A (81%), while 19% had phenotype C. The dietary survey revealed a significantly higher intake of saturated fatty acids in patients with PCOS (10.2±2.8% TEI vs 8.2±2.9% TEI; P = 0.01) and a significantly higher insufficiency in omega-6 fatty acid intake (58% vs 5%; P = 0.001) compared to the control group. The average energy intake, as well as protein, carbohydrate, and lipid intakes, were similar between the two groups. Regarding micronutrients, PCOS patients had significantly lower intakes of vitamin C (91±69 mg/d vs 142±85 mg/d; P = 0.01) and vitamin B1 (1,03±0,32 mg/d vs 1,24±0,42 mg/d; P = 0.04). Micronutrient intake deficiencies were also more frequent in PCOS patients compared to the control group, primarily affecting vitamin C (64% vs 23%; P = 0.002), vitamin B1 (29% vs 0%; P = 0.03), vitamin B3 (29% vs 0%; P = 0.003), vitamin B6 (35% vs 12%; P = 0.03), calcium (87% vs 65%; P = 0.05), and iron (48% vs 19%; P = 0.02).

Conclusion

This study underscores the prevalence of micronutrient Intake deficiencies in overweight women with PCOS. These findings suggest the need for targeted dietary interventions to address nutrient intake imbalances in this population, contributing to a better management of PCOS symptoms and long-term health outcomes.

A study of interleukin-6 gene polymorphism in egyptian obese subjects

Marwa Salah[1], Ibrahim Abdelrahman[2], Mohammed Mahmoud[2], Eman Saad[2] & Pakinam Aly[2]
[1]Faculty of Medicine, Alexandria University, Egypt, Internal Medicine, Endocrine Division, Alexandria, Egypt; [2]Faculty of Medicine, Alexandria, Egypt

Background
Polymorphisms in the interleukin 6 gene have been studied in various chronic diseases. Increased levels of IL-6 in humans have been associated with visceral fat accumulation and obesity. The aim of the work was to study interleukin-6 gene polymorphism in Egyptian obese patients.
Methods
A total of 100 people were enrolled in the study. They were divided into: Group A included 35 subjects of simple obesity, group B included 35 patients of complicated obesity, and group C included 30 healthy subjects. Laboratory investigations were done for all subjects including IL-6 gene snp rs1800796 polymorphism, uric acid, amylase, lipase, C reactive protein and lipid profile. Abdominal ultrasound was done to assess presence of fatty liver and/or fatty pancreas.
Results
Regarding the IL-6 gene polymorphism, there was no significant difference statistically between both obese groups, however there was a significant difference statistically among obese groups and healthy people. Employing an univariate regression; waist circumference, hip circumference, waist/hip ratio, uric acid, cholesterol, C reactive protein, GG allele of IL-6 ($P < 0.001$), fatty liver and/or fatty pancreas ($P < 0.001$) were statistically significant parameters for obesity. In multivariate analytical regression; uric acid ($P = 0.041$), and the GG allele of IL-6 polymorphism ($P = 0.028$) were statistically significant risk factors for obesity.
Conclusions
IL-6 gene snp rs1800796 polymorphism was associated with increased risk of obesity. The obesity traits were linked to G allele. Future studies on gene-environment interactions should be carried out to clarify the connection between the IL-6 polymorphism and obesity.

Mitraa: transforming patient care through ai-driven chatbot technology

Bharat Saboo[1], Alok Modi[2] & Aniket Inamdar[3]
[1]Prayas Diabetes Center, Diabetes and Obesity, Indore, India; [2]Kewalya Hospital, Thane, India; [3]Samarpan Clinic, Omerga, India

Aim
This study aims to evaluate the impact of Mitraa, an AI-based chatbot, on patient care, focusing on its effectiveness in improving medication adherence, patient engagement, and reducing unnecessary clinic visits.
Materials and Methods
A pilot study was conducted involving 100 patients with chronic conditions. Participants were provided access to Mitraa, which offers personalized, real-time health support, including medical information, medication reminders, lifestyle recommendations, and continuous monitoring. The chatbot leverages natural language processing (NLP) and machine learning algorithms to adapt to individual patient needs. Data on medication adherence, patient engagement, satisfaction, and clinic visit frequency were collected over a three-month period.
Results
Mitraa demonstrated significant improvements in patient outcomes. Medication adherence rates increased by 35%, and patient engagement rose by 40% during the study period. Additionally, 85% of users reported higher satisfaction with their healthcare experience, attributing this to Mitraa's accessibility and personalized guidance. The chatbot also contributed to a 25% reduction in unnecessary clinic visits, alleviating the burden on healthcare facilities.
Conclusion
Mitraa effectively enhances patient care by providing continuous, personalized support and bridging the gap between healthcare providers and patients. The observed improvements in adherence, engagement, and patient satisfaction highlight the chatbot's potential to foster proactive, patient-centered care. By reducing the strain on clinical resources and empowering patients to manage their health, Mitraa contributes to more efficient healthcare delivery and healthier communities.

Phenotyping in obesity: to whom are we prescribing semaglutide and tirzepatide?

Ercole Franco[1,2], Valentina Pasquali[1,2], Federica Pippa[1,2], Emmanuele Capobianco[1,2], Federica Delfini[1,2], Ida Sicilia[1,2], Beatrice Baldini[1,2], Uberto Pagotto[1,2] & Silvia Garelli[1]
[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy., Division of Endocrinology and Diabetes Prevention and Care, Bologna, Italy; [2]Alma Mater Studiorum University of Bologna, Bologna, Italy., Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy

Introduction
Obesity is a chronic and relapsing disease that has been increasing in prevalence in the last decades. Two new drugs become available in Italy in the past year (July for Semaglutide and October for Tirzepatide) for the treatment of this condition. In clinical trials these molecules showed very promising efficacy and tolerability. However, clinical practice differs from clinical trials, especially when it comes to drugs that have a significant cost for the patient. As of today, no data exist on efficacy, tolerability and adherence of Semaglutide and Tirzepatide treatment in the Italian population.
Aim
To phenotype the patients that are willing to start a treatment with anti-obesity medication (Semaglutide or Tirzepatide) and follow them up to evaluate efficacy, tolerability and adherence to these molecules.
Methods
We collected anamnesis (including occupation), anthropometric measures, presence of obesity related comorbidities in 73 patients that were willing to start pharmacological treatment for obesity in our Division of Endocrinology and Diabetes Prevention and Care. Afterwards the pharmacological treatment was initiated and at 3-month follow-up was performed registering patients' weight, Hunger and Satiety VAS scales.
Results
The mean age was 51.9 years, the mean BMI 37.90 kg/m^2 and most patients were female 79% ($n = 57$). The most prevalent comorbidity was dyslipidemia, followed by hypertension and prediabetes. These were present respectively in 49,44 and 30% of the population. Even if these complications were common, end organ damage defined as myocardial infarction, ischemic stroke and kidney failure were rare (3% of the population). Analyzing the net income of our patients we were able to divide the population into three categories: below 20.000 €/year, between 20.000-30.000 € /year and more than 30.000 €/year. Almost all the population fit in the first and second categories (respectively 24 and 32 patients). When we performed the analysis, 37 patients reached the 3-month follow-up, with 3 patients that suspended the drug or did not start the therapy at all. Of the 34 patients still in therapy the average weight loss was 5%. Furthermore, the "hunger" scale was significantly reduced after 3 months, and the "satiety" scale was significantly increased.
Conclusions
Our study shows that, in a classic endocrinological setting, the population that starts Semaglutide or Tirzepatide is young, with multiple comorbidities but very few end organ damage. Furthermore, these drugs seem safe and effective also in clinical practice and used not only by the people of the highest socioeconomical status but by a heterogeneous population.

Real-life experience of semaglutide in the treatment of idiopathic intracranial hypertension: a case series

Gilberto Claro Teixeira[1], Christian Stallinger[2], Ben Schloesser[3], Tania Navarro[4] & Maria Tichomirowa[3]
[1]University of Luxembourg, Belval, Luxembourg; [2]Centre hospitalier du Nord, Ettelbrück, Luxembourg; [3]Centre hospitalier du Nord, endocrinology, Ettelbrück, Luxembourg; [4]Neurology private office, Ettelbrück, Luxembourg

Introduction
Idiopathic Intracranial Hypertension (IIH) is a disorder characterized by elevated intracranial pressure (ICP) without an identifiable cause. It primarily affects obese women and is associated with headaches, papilledema, and visual disturbances. The prevalence of IIH has increased with rising obesity rates. Weight loss remains the mainstay of treatment, and glucagon-like peptide-1 receptor agonists (GLP-1RAs), such as semaglutide, have demonstrated effectiveness in metabolic control and weight reduction.
Methods
We retrospectively analyzed four female patients diagnosed with IIH who received semaglutide as part of their weight loss and ICP management strategy. The BMI before and after therapy, headache frequency and severity, and changes in visual symptoms were documented.
Results
Patient 1: A 38-year-old woman with BMI 28.7 kg/m^2 at baseline presented with perimenstrual migraines, visual impairment, and tinnitus. After 12 months of semaglutide therapy, her BMI reduced to 27.3 kg/m^2. Her monthly headache days (MHD) decreased from 30 to 15, with no visual disturbances. Patient 2: A 39-year-old woman with a history of gastric bypass and obesity (BMI 33.79 kg/m^2) experienced persistent holocephalic pressure and severe headaches. Following 10 months of semaglutide therapy, her BMI dropped to 27.3 kg/m^2, and MHD decreased from 30 to 15, with an intensity reduction from 7/10 to 3–5/10. Patient 3: A 48-year-old woman with hypertension and diabetes was diagnosed with IIH and papilledema (BMI 42 kg/m^2). After 6 months of semaglutide therapy, she lost 6 kg (BMI 40.4 kg/m^2), and her headaches completely resolved. Acetazolamide therapy was maintained, and no recurrence of symptoms was noted. Patient 4: A 34-year-old woman diagnosed with IIH in 2021 had a BMI of 35.3 kg/m^2 (96 kg, 165 cm). Due to polycystic ovary syndrome (PCOS), she was started on semaglutide, spironolactone, and metformin in 2022. After 18 months of therapy, she experienced significant weight loss (BMI reduced to 28.3 kg/m^2, 77 kg) and complete resolution of headaches. At her January 2025 follow-up, she was pregnant with recurrent headaches.
Discussion
All four patients demonstrated significant weight loss, headache reduction, and improved quality of life with semaglutide therapy. BMI reductions ranged from 6.3% to 25%. No patients exhibited progressive visual impairment, and two achieved complete headache resolution. GLP-1RAs promote weight loss and may directly affect intracranial pressure via GLP-1 receptors in the choroid plexus, supporting their potential role in IIH management.
Conclusion
Semaglutide represents a promising adjunct therapy for IIH, weight reduction and headache relief, potentially impacting intracranial pressure regulation.

The role of continuous glucose monitoring systems (CGMS) in early detection of glycemic abnormalities in obese populations with normal or impaired fasting glucose

Ashraf Soliman[1], Noor Hamed[1], Mohamed AlKuwari[1], Nada Alaaraj[1], Ahmed Elawwa[1], Shayma Ahmed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Continuous Glucose Monitoring Systems (CGMS) have revolutionized the detection of glycemic abnormalities, providing detailed insights into glucose variability, especially in obese populations.
Objective
To evaluate the benefits of CGMS in diagnosing and managing glycemic abnormalities in obese individuals with normal fasting glucose, impaired fasting glucose, or other glucose tolerance abnormalities.
Methods
A comprehensive review of CGMS studies from 2000 to 2024 was conducted. Studies were selected based on their focus on obese children, adolescents, and adults with normal or impaired fasting glucose. Outcomes assessed include the detection of postprandial hyperglycemia, glycemic variability, nocturnal hypoglycemia, and overall glucose profiles.
Results
CGMS has demonstrated significant benefits across multiple studies:.
1. **Enhanced Detection:** CGMS uncovered glycemic abnormalities in up to 30% of individuals with normal fasting glucose, including postprandial hyperglycemia and nocturnal-hypoglycemia, which were undetectable by fasting glucose or HbA1c measurements.
2. **Identification of Glycemic Variability:** Approximately 45% of subjects with normal glucose tolerance exhibited significant glycemic variability, highlighting the utility of CGMS in identifying transient glucose excursions.

Table 1.

Population	Key Findings	Benefits of CGMS
Obese children and adolescents	CGMS detected impaired glucose tolerance in 25% and early glycemic abnormalities in 30% of cases.	Early detection and intervention in pediatric populations.
Obese adults with normal fasting glucose	30% showed postprandial hyperglycemia and significant glucose fluctuations not detected by fasting glucose.	Identification of postprandial and nocturnal hyperglycemia.
Obese first-degree relatives of T2DM patients	40% exhibited abnormal glycemic profiles despite normal fasting glucose levels.	Improved risk stratification for genetically predisposed individuals.

3. **Early Diagnosis in High-Risk Groups:** CGMS identified abnormal glycemic profiles in 40% of obese first-degree relatives of type 2 diabetes patients, emphasizing its role in early detection among genetically predisposed individuals.
4. **Improved Screening in Pediatric Populations:** Among obese children and adolescents, CGMS detected impaired glucose tolerance in 25% of cases and revealed early glycemic abnormalities in up to 30%, many of which were missed by OGTT or fasting glucose tests.
5. **Dynamic Glycemic Profiles:** CGMS captured real-time data on glucose fluctuations, allowing clinicians to detect postprandial glucose excursions exceeding 7.8 mmol/lin 30% of participants with normal glucose tolerance.
Conclusion
CGMS offers unparalleled benefits in detecting and managing glycemic abnormalities in obese individuals, even those with normal FPG. By capturing real-time glucose fluctuations and variability, CGMS allows early identification of at-risk individuals and supports timely, personalized interventions. Future research should explore cost-effectiveness and long-term outcomes of CGMS-guided interventions in these populations.

Comprehensive insights into metformin: evidence from *in vitro*, cellular, animal, and human studies on obesity and cardiovascular health"

Ashraf Soliman[1], Noor Hamed[1], Anas Abdulkayoum[1], Nada Alaaraj[1], Fawzia Alyafei[1] & Shayma Ahmed[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Metformin, widely used for managing type 2 diabetes, has demonstrated significant benefits in addressing obesity-related metabolic and cardiovascular complications. Its anti-inflammatory, antioxidative, and lipid-modulating properties position it as a potential therapeutic option for reducing obesity-related cardiometabolic risks.
Methods
This review synthesizes evidence from cellular, animal, and clinical studies to explore metformin's mechanisms of action and its impact on metabolic and cardiovascular parameters in obese patients and adolescents. Key outcomes assessed include inflammation, oxidative stress, lipid profiles, vascular health, and cardioprotective effects.
Results
1. Mechanisms of Action: Metformin activates AMP-activated protein kinase (AMPK), reducing inflammation and oxidative stress in adipose tissue, the liver, and blood vessels. It decreases pro-inflammatory cytokines (e.g., TNF-α, IL-6) and inhibits the NF-κB pathway, shifting macrophages from pro-inflammatory (M1) to anti-inflammatory (m^2) states, thereby lowering metabolic and cardiovascular risks.
2. *in vitro* Findings: Metformin reduces inflammation, oxidative stress, and vascular smooth muscle cell proliferation in atheroma cells. It stabilizes plaques by enhancing autophagy and reducing reactive oxygen species (ROS) production, lowering the risk of rupture and atherosclerosis-related complications.
3. Animal Studies: In obese animal models, metformin improved endothelial function, reduced systemic inflammation, enhanced lipid metabolism, and demonstrated cardioprotective effects, including reduced myocardial ischemia and infarct size.
4. Clinical Impacts:.
• Blood Pressure and CIMT: Metformin lowered systolic and diastolic blood pressure by improving insulin sensitivity and reducing oxidative stress, also decreasing carotid intimal-medial thickness (CIMT), a marker of early atherosclerosis.
• Atherogenic Index: Metformin improved the ratio of triglycerides to HDL cholesterol, contributing to lower cardiovascular risk in obese patients and adolescents.

Table 1. Summary of Metformin's Effects.

***in vitro* Studies**	**Reduced inflammation and oxidative stress in atheroma cells; inhibited VSMC proliferation; stabilized plaques.**
Cellular Studies	Activated AMPK; reduced pro-inflammatory cytokines (TNF-α, IL-6); shifted macrophages from M1 to M2 state.
Animal Studies	Improved endothelial function; reduced systemic inflammation, oxidative stress, and myocardial ischemia; enhanced lipid profiles.
Human Studies	Lowered BMI (3-5%), blood pressure (~5%), CIMT (~10%); improved insulin sensitivity (~15-20%) and lipid profiles (~5-8%).

• Lipid and Metabolic Effects: It lowered triglycerides, LDL cholesterol, and BMI while increasing HDL cholesterol and insulin sensitivity, with modest improvements in BMI and metabolic markers in adolescents.

Conclusions

Through its multifaceted mechanisms of action, metformin demonstrates significant potential in managing obesity-related metabolic and cardiovascular risks. By improving insulin sensitivity, lipid metabolism, and vascular health while reducing inflammation and oxidative stress, metformin offers a promising strategy for mitigating obesity's cardiometabolic complications.

Metformin in pediatric obesity: a safe and effective solution for lasting metabolic benefits

Noor Hamed[1], Ashraf Soliman[1], Anas Abdulkayoum[1], Nada Alaaraj[1], Shayma Ahmed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background

Pediatric obesity is a growing global health challenge, often linked to metabolic complications such as insulin resistance and type 2 diabetes mellitus (T2DM). Metformin, a staple medication for T2DM, has gained attention for its potential to manage obesity and associated cardiometabolic risks in children and adolescents. This review evaluates evidence from 19 studies to assess metformin's efficacy and safety in addressing pediatric obesity.

Methods

A total of 19 studies were analyzed, including 10 randomized controlled trials (RCTs) involving 657 patients, an open-label extension study with 42 participants, a retrospective review of 78 patients, a meta-analysis, and 5 narrative reviews. The studies spanned from 2008 to 2024 and investigated metformin's effects on body mass index (BMI), insulin sensitivity, and other metabolic parameters in obese pediatric populations.

Results

Efficacy:.

• Across the studies, metformin consistently reduced BMI and improved insulin sensitivity, with high-quality RCTs demonstrating significant metabolic benefits, particularly in prepubertal children and those with insulin resistance.

• Studies such as Yanovski *et al*. (2011) and Pastor-Villaescusa *et al*. (2017) reported modest yet meaningful BMI reductions and enhancements of metabolic markers.

• Observational studies and systematic reviews supported these findings, reinforcing metformin's role as a cost-effective intervention for managing pediatric obesity.

• The strongest benefits were observed in patients with baseline insulin resistance, with consistent improvements in BMI Z-scores, fasting insulin levels, and body composition.

Safety:.

• Metformin displayed a favorable safety profile across all studies. Common side effects, including mild gastrointestinal discomfort, were transient and self-limiting.

• No serious adverse events were reported, even in long-term studies.

Patient Impact:.

• The review included 777 patients across various study types. Prepubertal children and those with insulin resistance exhibited the most substantial benefits, with improved BMI Z-scores, metabolic health, and body composition.

Conclusions

Metformin is a safe and effective intervention for managing pediatric obesity, particularly for patients with insulin resistance. Robust evidence supports its use in reducing BMI and improving metabolic health, with the greatest benefits observed in prepubertal children. While its long-term effects require further investigation, current evidence positions metformin as a valuable tool for combating pediatric obesity and its cardiometabolic complications.

Body composition and metabolic complications in a single-centre pilot cohort of adults with X-linked hypophosphatemia

Marko Stojanovic[1], Dragana Miljic[1], Mirjana Doknic[1], Sandra Pekic Djurdjevic[1], Zvezdana Jemuovic[2], Ivana Cekic[2], Ivan Jevtic[2], Boris Kurcubic[2], Jelena Bajic[2] & Marina Nikolic Djurovic[1]
[1]Medical Faculty, University of Belgrade, Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department of Neuroendocrinology, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Department of Neuroendocrinology, Belgrade, Serbia

Background and Aim

X-linked hypophosphatemia (XLH) is a rare genetic disease hallmarked by hypophosphatemia and osteomalacia with skeletal deformities, caused by autonomous over-secretion of fibroblast growth factor 23 (FGF-23). Obesity is frequently observed in XLH patients, attributed to impaired mobility, but possibly also linked to direct negative metabolic effects of elevated circulating FGF23. Recent research suggests that adult XLH patients are obese with excess fat mass, but without increased prevalence of metabolic dysfunction.

Patients and Methods

Cross-sectional pilot study included a single-centre cohort of 9 adult XLH patients (8 female), 39.9 $\pm$ 4.6 years old, treated with active vitamin D and phosphate supplements. Anthropometric analysis included weight, height, BMI, and waist to hip circumference ratio (WHR). Body composition was analysed by DXA whole body scan - WBS (Hologic Discovery QDR). Total body fat percent (Fat%) was expressed as fraction of the upper limit of normal age and gender values (Fat%ULN). Fasting blood glucose and fasting insulin were used to calculate HOMA IR. Abdominal ultrasound was performed to screen for liver steatosis.

Results

The average body weight (60.33 $\pm$ 3.45kg) and BMI (29.24 $\pm$ 1.81 kg/m^2) were on the borderline of overweight and obesity. Four patients were obese (44.4%) and 3 (33.3%) overweight. Average WHR (0.79 $\pm$ 0.02) was below the threshold for abdominal obesity. DXA WBS revealed the average total body fat mass (FM) of 23.46 $\pm$ 2.6kg, the average total lean body mass (LMB) of 35.75 $\pm$ 1.93kg. The average Fat% of 37.73 $\pm$ 2.68%, translated to 0.89 $\pm$0.05 Fat%ULN. The average baseline insulin level was 16.30 $\pm$ 2.82 mIU/land the average HOMA IR was 3.56 $\pm$ 0.56. Seven patients (77.8%) had HOMA IR $>$ 2.4. Abdominal ultrasound revealed liver steatosis in 1 of 9 patients (11.1%).

Conclusions

Adult XLH patients in our pilot single centre cohort were predominantly overweight and obese but with average total body fat percent not exceeding upper limit of age and sex normal values and with average waist to hip ratio indicating low metabolic risk. Prevalence of liver steatosis upon sonography was low. However, average insulin resistance was higher than previously reported, possibly linked to factors beyond the obesity or body composition. Further research may elucidate correlation of insulin resistance with circulating FGF23 and the effects of anti-FGF23 antibody treatment on metabolic status in XLH patients.

Long-term efficacy and safety of semaglutide in the treatment of syndromic obesity in prader willi syndrome - case series

Mojca Jensterle[1], Andrijana Koceva[2], Katarina Mlekus Kozamernik[1], Rok Herman[1] & Andrej Janez[1]
[1]University Medical Center Ljubljana, 1000 Ljubljana, Slovenia, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]University Medical Center Maribor, 2000 Maribor, Slovenia, Department of Endocrinology and Diabetology, Maribor, Slovenia

Introduction

Prader-Willi syndrome (PWS) is the most prevalent cause of syndromic obesity. Obesity development in PWS is driven by dysfunction in neural pathways

involved in satiety and reward, dysregulation in hormones regulating satiety and food intake, altered body composition and reduced energy expenditure, as well as the presence of various hormone deficiencies. As hyperphagia, satiety dysfunction and consequent food-seeking behaviors are intrinsic to PWS, obesity management can be challenging.
Case series
We present a long-term follow-up of treatment with GLP-1 receptor agonist (GLP-1 RA) semaglutide, up to 37 months, in three patients with PWS without diabetes. Patient 1 was a 28-year-old female with PWS, resulting from uniparental disomy, with BMI 50.8 kg/m^2. She was initially treated with a calorie-restricted diet and subsequently admitted to a specialized "group home center", however, her weight continued to progressively increase. Patient 2 was a 39-year-old female with PWS resulting from mosaic maternal uniparental disomy who underwent metabolic surgery at the age of 29, first a gastric band surgery and subsequently Roux-en-Y gastric bypass. Despite an initial weight loss of approximately 50 kg, she ultimately regained most of her lost weight. Before treatment with semaglutide she reached her maximum weight of 174 kg, her BMI was 82.8 kg/m^2. Patient 23 was a 25-year-old male with PWS, resulting from a uniparental maternal disomy, with body mass index (BMI) 41.3 kg/m^2. Semaglutide treatment at dosages from 0.5 mg to 2 mg weekly demonstrated variable efficacy, from preventing further weight gain in Patient 1 to achieving weight loss of up to 14.4% and 11% relative to baseline, in Patient 2 and Patient 3, respectively. All patients reported appetite suppression and increased satiety during semaglutide treatment, which was diminished during short term treatment interruptions due to drug unavailability. Mild transient gastrointestinal-related side effects were reported during dose escalation in the case of Patient 2, who had a history of metabolic surgery. No serious adverse events were reported during the observation period.
Conclusions
Following a personalized approach, GLP-1 RAs may have the potential to address the hallmark challenges of hyperphagia, obesity and metabolic dysfunction associated with syndromic obesity in PWS, with mild to moderate efficacy. Future research should prioritize long-term randomized placebo-controlled trials with larger sample sizes to provide stronger evidence on the long-term efficacy and safety of incretin therapies for obesity treatment in PWS as well as explore the potential synergistic effects combined with other therapeutic interventions.

Abdominal adipose tissue ultrasound characterization in patients living with excess body fat: experience from our Centre
Carolina M. Perdomo[1,2,3], Adrián Gil Korilis[1], Henar Casal[1], Marta Zaballos[1], Isabela Valdes[1], Patricia Yárnoz[1], Camilo Silva[1,2,3], Gema Fruhbeck[1,2,3] & Javier Escalada[1,2,3]
[1]Clínica Universidad de Navarra, Pamplona, Spain; [2]IdiSNA, Pamplona, Spain; [3]CIBERObn, Pamplona, Spain

Background
Ultrasound measurement of abdominal fat is precise, reliable, inexpensive, with measurement accuracy equivalent to computed tomography and magnetic resonance imaging. Despite this, widespread adoption has been hampered by lack of experience or reliable standard operating procedures. The aim of our study was to characterize the adipose tissue layers of the abdominal wall trough ultrasound assessment in patients with excess body fat assess and compare our results with recent proposed guidelines.
Methods
Retrospective transversal study including 103 adult patients who underwent abdominal wall ultrasound at Clínica Universidad de Navarra. Exclusion criteria included BMI <25 kg/m^2 with normal fat mass. Fat mass was quantified by Clínica Universidad de Navarra-Body Adiposity Estimator. Ultrasound scan was performed in the midpoint between the xiphoid appendix and the navel (1-3 cm above the umbilicus) along the alba line.
Results
Mean age was 46.6 $\pm$ 14.4 years and 74.8% were women. Fifty patients (49%) were under GLP-1 analogs. After excluding patient treated with GLP-1 analogs, subcutaneous adipose tissue was moderately (P <0.05) correlated to preperitoneal adipose tissue (r = 0.41), BMI (r = 0.32), tryglicerides level (r = 0.32), the presence of diabetes (r = 0.34), dyslipidemia (r = 0.38) and with the number of metabolic abnormalities (r = 0.29). Preperitoneal adipose tissue was correlated with BMI (r = 0.36), ALT levels (r = 0.28) and triglycerides (r = 0.39). Patients with a subcutaneous adipose tissue measurement >1.8 cm (median value), had a strong correlation with the number of metabolic abnormalities (r = 0.49; P <0.01).
Conclusions
Ultrasound abdominal wall characterization must include the measurement of subcutaneous adipose tissue maximum thickness as it is associated with the presence of metabolic abnormalities, and therefore, metabolic risk. Identification and management/decrease of excess adiposity must be a target in a primary and secondary prevention setting. Abdominal wall ultrasound assessment may be an adequate target in the daily clinical setting.

Treatment of hypercholesterolemia with natural compounds
Rihab Ben Abdallah Kolsi[1], Kolsi Boulbaba[2] & Lotfi Feki[3]
[1]Faculty of Sciences of Sfax Tunisia, Sfax, Tunisia; [2]CHU Hedi Chaker Sfax Tunisia, Sfax, Tunisia; [3]Faculty of Sciences of Sfax Tunisia, Sfax, Tunisia

Obesity is considered as an exceeding life style disorder notably in developing countries and it is prevailing at a frightful speed in new world countries as a result of fast food intake, causing raised blood cholesterol levels, which in turn can damage many systems in the body. The present study investigates the hypolipidemic effects of sulphated polysaccharide obtained from a green algae in induced obese subjects (High Fat Diet). The results showed an increase in body weight of HFD subjects by 27.09% as compared to control normal group. Moreover, serum lipase activity underwent an increase which led to an increase in the levels of total cholesterol (T-Ch), triglycerides (TG) and low density lipoprotein cholesterol (LDL-Ch) in serum associeted with a decrease in the level of high density lipoprotein cholesterol (HDL-Ch) in untreated HFD rats. This diet has disrupted the antioxidant status by decreasing the activities of antioxidant enzymes (superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPX)) and subsequently an increase in thiobarbituric acid reactive substances (TBARS) level in liver and kidney of obese rats. All these disturbances are significantly corrected by extract administration with no fatty deposits in the liver and a protective effect against renal histological alteration. This confirms the important role of this polysaccharide in the fight against oxidative stress and the prevention of hyperlipidemia.

F18 Choline PET-CT scan as single imaging modality for primary hyperparathyroidism
Safaa Malkat[1], Vidhu Nayyar[1], james Clark[1], Ben Field[1], Julian Emmanuel[1], Despoina Tseke[1], kavitha Lakshmipathy[1] & Sunil zachariah[1]
[1]Department of Endocrinology, Surrey and Sussex Healthcare NHS Trust, Redhill, UK, Redhill, United Kingdom

Case History
We present a case of a 63-year-old female who presented with nausea, weight loss, constipation, low mood, and headache. The patient's past medical history included rheumatoid arthritis and a fractured ankle. There was no previous history of renal stones, nor a family history of hypercalcemia. Blood tests revealed normal renal function, low vitamin D levels (which were sufficiently replenished), elevated adjusted calcium at 2.96 mmol/l(reference range: 2.2–2.6 mmol/L), elevated parathyroid hormone at 26.4 pmol/l(reference range: 1.6–6.9 pmol/L), and a urinary calcium-creatinine ratio of 2.23. Primary hyperparathyroidism (PHPT) was diagnosed. Although Sestamibi scan and parathyroid ultrasound did not identify parathyroid adenoma. However, A PET-CT with F18 choline identified a left inferior parathyroid adenoma. Additionally, renal ultrasonography detected a non-obstructive 4 mm kidney stone. The patient left inferior parathyroid adenoma was surgically removed and her symptoms and biochemistry improved, including serum calcium levels normalized to 2.25 mmol/L. In primary hyperparathyroidism (PHPT), surgical intervention is the only curative option when appropriate. Therefore, precise localization of the parathyroid adenoma is crucial for successful surgical management. Radiolabelled choline PET-CT has emerged as a novel imaging modality, demonstrating significant promise for accurate lesion localization. We note a series of ten patients in whom ultrasound and MIBI scans failed to detect definitive parathyroid adenomas. In all

these cases, F18 choline PET-CT successfully identified the lesion, enabling curative surgical intervention. In fact, in two of the ten instances, a parathyroid adenoma was identified in the mediastinum and would have been overlooked if exploratory parathyroidectomy was undertaken. Recent research demonstrated that F18 choline PET-CT has a higher preoperative diagnostic efficiency than ultrasound and MIBI scans, with a positive predictive value of 90.9%. We propose F18 choline PET-CT as a primary imaging modality to augment, current imaging with Ultrasound, MIBI scintigraphy, and 4D CT, due to its superior diagnostic performance. However, further clinical research is needed, and cost as well as local availability remain important considerations.

Hyperglycemia in patients with acute myocardial infarction

Mehriban Rizaeva[1], Zulaykho Shamansurova[2], Matluba Badritdinova[1], Barno Badriddinova[1], Mohammed Abdul Haseeb[3] & Ravshankhon Turgunovna[4]
[1]Bukhara State Medical Institute, Endocrinology, Bukhara, Uzbekistan; [2]Central Asian University, Endocrinology, School of Medicine, Tashkent, Uzbekistan; [3]Kimyo International University In Tashkent (KIUT), Tashkent, Uzbekistan; [4]Centre for the development of professional qualification of medical workers, Tashkent, Uzbekistan

Introduction
Acute Myocardial Infarction (AMI) frequently accompanied with hyperglycemia, either transient or due to impaired glucose tolerances or DM. Usually hyperglycemia during AMI in healthy non-diabetic person viewed as a reflection to the acute stress condition. Despite there a many studies regarding that transient hyperglycemia, management is under discussion. The aim of our study was estimation of frequency of hyperglycemia in people with AMI.
Materials and Methods
Cases of AMI in Bukhara city were analyses based on two main hospitals in Bukhara during 2022/2023 were analyzed retrospectively by patients chart. Second part of investigation were conducted prospectively with daily multiple blood sugar level control.
Results
Medical records from 997 patients, whose were admitted to the hospitals due to AMI shown that 66% of patients has Dm^2. There were no information about transient hyperglycemia. Analysis of early in hospital death rate were estimated about 10.2% and were detected only in patients with Dm^2. Prospective study were conducted in 170 people who admitted into mentioned above hospitals due to AMI. Among in-hospital admitted AMI patients 104 (61,18%) were people with Dm^2, in 42 (24,7%) people transient hyperglycemia were detected and 24 (14,1%) people were without any carbohydrate disturbances. Interestingly, in patients with AMI we can see wide fluctuations of blood glycemia level. We divided patients according to glycemia fluctuation during the day: between 4 and 11Mmol/las normoglycemia, higher than 11Mmol/las a hyperglycemia and if blood sugar level less than 4Mmol/lwere defined as hypoglycemia. Hyperglycemia episodes (24.86%) were 10 times frequent than hypoglycemia (2.16%). All patients blood sugar were tightly controlled during the day and if needed they were received hypoglycemic treatment according to blood glycemia level. Early in-hospital death rate were among prospective study groups were more less than in retrospective patients 2.9% vs 10.9%. HbA1c level in patients after 3 months were in acceptable range in 66% of Dm^2 group and 88% of transient hyperglycemia group and remain high in 33% of Dm^2 and 11% of transient hyperglycemia group and suggested about inportance of tight glycemic control in that patients.
Conclusion
Hyperglycemia were frequent future in patients with AMI and presented in 85.88% cases, 61.18% were patients with Dm^2 and 24.7% with transient hyperglycemia. Hyperglycemia episodes were 10 times higher than hypoglycemia. Intensive control of blood glycemia with appropriate hypoglycemia measurements help to reduce in-hospital mortality rate.

Metabolic changes and satisfaction associated with gender-affirming hormone therapy in transgender women

Emilia Gomez Hoyos[1], Lucia Estevez Asensio[1], Esther Delgado Garcia[1], Marta Mesonero Alonso[1], Maria Jose Bartolome Albistegui[1], Ruth Gonzalez Collantes[1], Maria Antonia Maniega Rubio[1], Carmen Rodriguez Fernandez[1], Ana Casas Marcos[1] & Daniel De Luis[1]
[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain

Introduction
Gender affirming hormone therapy (GAHT) in transgender women favors their feminization. Aims: To determine its metabolic impact and the satisfaction perceived by the subject (CRES-4 questionnaire).
Material and Methods
Prospective study in transgender women with GAHT (> 2 years), attended at the Transgender Medicine Unit of the Hospital Clinico of Valladolid from January 2014 to January 2023. Recording of clinical, analytical and CRES-4 questionnaire data after giving their consent. Statistical analysis of the data by the SPSS-V17 program.
Results
36 transgender females aged 31 [23-42] years and onset of GAHT at 21 [17-30] years with oral estradiol 21 (58%) and transdermal estradiol 15 (42%). Besides 27 (75%) with cyproterone acetate and 9 (25%) with spironolactone. The initial BMI was 22 [20-25] kg/m^2, Total Cholesterol 160 [133-185], LDL 78 [69-129], HDL 54 [69-129], TG 76 [60-107] mg/dl. At 2 years with GAHT, BMI was 23[20-27] kg/m^2 (p 0.0939, the increase was 0.12 [-0.69 to 0.79] with oral estradiol and the 0.92 [-0.34 to 1.45] with transdermal estradiol (p 0.250). Total Cholesterol was 164 [140-188] (p 0.610), LDL 87 [63-127] (p 0.184), HDL 51 [40-72] (p 0.245) and Triglycerides was 72 [55-96] mg/dl (p 0.215). In trans women with oral estradiol the change of HDL was 12 [3-19] compared to - 3.5 [-11 to 14.25] mg/dl with transdermal estradiol (p 0.002). Subjects were satisfied with GAHT, with 250 [232-271] points on CRES-4. In women with oral estradiol was 250 [235-275] and transdermal estradiol 262 [230-277] (p 0.085).
Conclusion
Feminization hormone therapy induces a non-significant increase in BMI without deterioration of the lipid profile, with a significant increase in HDL cholesterol, mainly in women with oral estradiol. Although the satisfaction associated with hormonal therapy appears to be greater in women with transdermal estradiol.

Effect of a nutritional education program on anthropometric, biochemical, and body composition parameters in obese patients

Cristian Jesús Lucena Morales[1], María González Pacheco[1], Carlos López Pereira[1], Almudena Lara Barea[1] & Francisco Javier Vílchez López[1]
[1]Hospital Universitario Puerta del Mar, Endocrinology and Nutrition Department, Cádiz, Spain

Introduction
Obesity is a major public health concern linked to higher morbidity and mortality. Nutritional education programs play a crucial role in promoting healthy habits and improving clinical, biochemical, and body composition parameters.
Materials and Methods
An observational before-and-after study was conducted on patients with obesity who participated in a 5-session program at the Endocrinology and Nutrition Unit of HUPM (January 2022 - October 2024). Clinical, anthropometric, biochemical, and body composition parameters were analyzed.
Results
A total of 101 patients participated (63.4% women, mean age 47 years, BMI 41.9 kg/m^2). Hypertension was present in 40.6%, dyslipidemia in 24.8%, type 2 diabetes in 17.9%, and prediabetes in 15.8%. Of these, 34.8% were treated with GLP-1 receptor agonists, showing greater but non-significant weight loss (8.9 $\pm$ 9.82 kg vs. 7.96 $\pm$ 5.44 kg). Baseline and final BIVA assessments were performed in 36 patients, with the following results: Patients with good adherence to the program lost more weight compared to those with poor adherence: A significant improvement in glycemic control was observed, as demonstrated in the biochemical parameters below:.

BIVA Parameters	Baseline (Mean $\pm$ SD)	Final (Mean $\pm$ SD)	p-value
Rz (Ohm)	481 $\pm$ 67.9	498.9 $\pm$ 62.9	$<$ 0.001
Xc (Ohm)	46.4 $\pm$ 7.78	47.3 $\pm$ 6.75	0.207
Pha (°)	5.53 $\pm$ 0.68	5.46 $\pm$ 0.64	0.272
TBW (L)	42.7 $\pm$ 7.63	40.3 $\pm$ 7.19	$<$ 0.001
FFM (Kg)	57.4 $\pm$ 9.84	55.2 $\pm$ 9.23	$<$ 0.001
FM (Kg)	51.1 $\pm$ 17.4	46.3 $\pm$ 15.6	$<$ 0.001
BCM	29.4 $\pm$ 4.27	28.1 $\pm$ 4.12	$<$ 0.001
ASMM (Kg)	23.7 $\pm$ 4.65	22.1 $\pm$ 4.25	$<$ 0.001

Program Adherence	Weight Loss (Kg, Mean ± SD)	Mean Difference	p-value
Poor (1-2 sessions)	3.56 ± 2.89	Intermediate - Poor = 1.32	0.652
Intermediate (3-4 sessions)	4.88 ± 4.95	Good - Intermediate = 5.25	0.003
Good (5 sessions)	10.13 ± 7.42	Good - Poor = 6.57	< 0.001

Laboratory values of cases.

Biochemical Parameters	Baseline (Mean ± SD)	Final (Mean ± SD)	p-value
Glucose (mg/dl)	100.11 ± 20.84	91.27 ± 15.35	0.005
HbA1c (%)	5.83 ± 0.81	5.59 ± 0.57	0.016
Total Cholesterol (mg/dl)	193.36 ± 45.57	179.93 ± 48.20	0.042

Conclusions
The nutritional education program improved anthropometric, biochemical, and body composition parameters. Participants who completed the program showed significant weight loss. No significant differences were found in weight loss between patients receiving GLP-1 treatment and those who did not. These results highlight the importance of nutritional intervention in managing obesity.

Morphofunctional changes during the follow up of people living with obesity treated with semaglutide

Roberto Carlos Romo Remigio[1], María Garcia Olivares[1], Lara Dalla Rovere[1], Carmen Hardy[1], Cristina Herola Cobos[1], Rocio Fernández Jimenez[1], Jose Abuin Fernandezmmmmd[1], Fracisco Hevilla Sachez[1] & Jose Manuel[1]
[1]QuironSalud Málaga Hospital, Endocrinology and Nutrition, Málaga, Spain

Introduction
Obesity is a chronic metabolic disease that causes multiple complications in the medium and long term. GLP1 Analogues, including Wegovy (Semaglutide) 2.4mg, are the medical treatment that achieves significant and sustainable weight loss. Morphofunctional assessment (MFA) techniques, such as Bioimpedanciometry (BIA) with phase angle (PhA), Nutritional Ultrasound (NU) ® (which includes Rectus Femoris (RF) ultrasound and abdominal adiposity ultrasound) and handgrip strength (HGS) allow us to evaluate changes in body composition, beyond the weight.

Table 1. The most significant data are presented in Table 1.

	Female		Male		Sig (p)
	Basal	**3rd month follow up**	**Basa**	**3rd month follow up**	SIG (P)
Weight (kg)	90,2±15,5	87,7±17,8	107±21	100±16,5	<0,001
Waist (cm)	106±13.6	105±17,2	121±14	112±9,1	<0,001
Hip (cm)	121±13,7	118±16,4	116±11,3	111±8,9	<0,001
Nº of Squats in 30 sec	19,9±5,9	22,3±5,11	20,7±4,6	23,7±2,25	<0,001
Average HGS	22,1±5,1	22,5±4,4	38±6,9	39,9±3,8	0,538
Phase-angle	5,9±0.65	5,8±0,45	6,4±0,79	6±0,79	0,048
Body Cell Mass (BCM)	27±3,61	26,1±3,5	38,3±5,44	36±3,2	<0,001

Adiposity Mass (FM)	39,9±11,6	38,4±13,1	38,7±12,7	32,6±10,6	<0,001
Rectus Femoris (RF) CSA	5±1	5±1,1	6,5±1,7	6,1±1	0,511
RF- Y axis	2±3,6	1,5±0,3	2,4±4,2	1,7±0,18	0,001
Lower limb – Subcutaneous adipose tissue (SAT)	2,14±0,74	1,28±0,45	2,10±0,7	1,12±0,35	0,001
Abdominal - SAT	3,18±1,52	2,56±1,45	2,72±0,82	1,8±0,85	0,001
Abdominal - SAT area	12,1±3,87	10,8±3,59	10,4±5,4	8,7±3,39	0,002
Visceral Adipose tissue Area	9±2,7	8,5±2,69	8,22±3,2	7,1±2,7	<0,001

Aim
To evaluate changes in body composition using MFA techniques in patients with Obesity undergoing treatment with Semaglutide.
Methods
Prospective observational study of patients living with obesity treated at the Obesity and Metabolism Unit of Quirónsalud Málaga Hospital. MFA data was collected using BIA-PhA (Akern) and ultrasound (Mindray® Z60) at the baseline visit and after 3 months of follow-up. Semaglutide doses were started and adjusted according to standard protocols and patients' tolerance.
Results
25 patients, of which 18 (72%) were women. The presence of comorbidity was evaluated using the AACE Scale: 2 patients had grade 0 (2.9%), 33 patients had grade 1 (47.1%), 35 patients had grade 2 (50%).
Conclusions
Treatment with Semaglutide, along with a dietary program and physical activity recommendations, helps to reduce weight, mainly at the expense of the adipose component. Lower limb muscular area and function is preserved after 3 months of a weight loss program using Semaglutide.

JOINT3965

Association between vitamin d levels at discharge, in-hospital complications and prevalence of obesity in post-critical care patients after admission to the icu for pneumonia covid-19

Víctor Simón-Frapolli[1], Rocío Fernández Jiménez[1], Jose Manuel Garcia-Almeida[1] & Francisco José Tinahones Madueño[1]
[1]Hospital Virgen de la Victoria, Malaga, Spain

Introduction
Vitamin D plays a crucial role in the regulation of the immune system in addition to bone metabolism. In the context of the COVID-19 pandemic, its impact on inflammation, antiviral immunity and modulation of the renin-angiotensin system has been shown to be relevant in reducing the severity of the disease. Low vitamin D levels in hospitalized patients have been associated with greater severity of the disease due to immune dysregulation, with a higher rate of severe complications, demand for intensive treatment and higher mortality. In addition, vitamin D deficiency has been closely related to metabolic disorders such as type 2 diabetes mellitus (DM) and obesity.
Objective
The aim of our study was to determine whether there are differences in the prevalence of DM, obesity (defined according to BMI and percentage of fat mass -FM%-) and sarcopenic obesity, rate of in-hospital complications and need for aggressive therapies during hospital admission in a cohort of post-critical patients who were admitted to the ICU for severe COVID-19 pneumonia, according to vitamin D levels at hospital discharge.
Method
Prospective observational study including 94 patients who were admitted to the ICU for severe COVID-19 pneumonia. At 2-3 weeks after hospital discharge, demographic, clinical and analytical data, medical history and morphofunctional assessment including bioimpedanciometry were collected. Patients were divided into three categories according to their serum vitamin D levels (deficit if $\leq$20 ng/ml, insufficiency if 20.01-29.99ng/ml, sufficiency if $\geq$ 30ng/ml). Differences in prevalence of DM, prevalence of obesity and in the rate of complications during admission were analyzed according to these vitamin D categories. For the definition of obesity according to FM% and sarcopenic obesity, the ESPEN and EASO consensus (2022) was followed.
Results
Depending on the categories of vitamin D deficiency, insufficiency and sufficiency, statistically significant differences in age (67±12,67±10,57±12; $P = 0.32$), sarcopenic obesity prevalence (36%,47%,43%; $P = 0.04$), days of ICU stay (25±9.5,33±9.8,19±9.4; 0.09), days of hospital stay (49±32,85±36,50±24; $P = 0.04$) and days of IMV (28±14,36±14,23±14; $P = 0.84$) were shown.
Conclusions
Statistically significant differences were observed in the prevalence of sarcopenic obesity (greater in the vitamin-D-deficiency and insufficiency vs. vitamin-D-sufficiency subgroups) and in days of hospital stay (greater in the vitamin-D-deficiency vs. sufficiency subgroup). When the multiple comparisons test was performed, differences were also observed in age, ICU stay and in days of IMV, being greater in the vitamin-D-deficiency vs. sufficiency group. No differences were observed in the prevalence of DM or obesity.

Familial inheritance and childhood obesity

Mouna Elleuch[1], Yesmine Elloumi[1], Khouloud Boujelben[2], Ines Ketata[3], Mouna Aboub[4], Mouna Mnif[2], Dhoha Ben Salah[2] & Nabila Rekik Mejdoub[1]
[1]Hedi Chaker University Hospital, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology department, Sfax, Tunisia; [3]Ben Arous Hospital, Sfax, Tunisia; [4]Bir Ali Hospital, Bir Ali, Tunisia

Background
Childhood obesity and overweight have emerged as alarming public health issues, affecting an increasing number of children worldwide. With significant implications for both physical and mental well-being, these conditions are rapidly becoming a societal challenge. The factors driving this trend remain complex and multifaceted, with parental influence playing a pivotal role. This study aims to shed light on these key factors.
Methods
This cross-sectional case-control study was conducted in 2022 among children attending school health clinics in Tunis, Tunisia. It included children aged 5 to 15 years, excluding the conditions causing secondary obesity. Overweight was defined as an age-specific body mass index (BMI) > 1 standard deviation (SD) above the median of the WHO growth standards, while obesity was defined as a BMI > 2 SDs above the median. Parental obesity was defined as a BMI $\geq$ 30 kg/m^2. Patients were divided into two groups: G1 (overweight or obese children) and G2 (normal weight children). A 41-item questionnaire was administered to both children and their parents, addressing the risk factors for obesity.
Results
A total of 216 patients were included in the study, with 54 classified as overweight or obese (G1) and 162 having normal weight (G2). We did not find a significant association between overweight or obesity and age ($P = 0.07$), although it was observed that overweight and obese children were generally younger (7 years (6-12) in G1 vs. 11 years (6-12) in G2). The prevalence of overweight or obesity was higher in male children (34 (36.2%) in males vs. 20 (22.2%) in females, $P = 0.038$). There was no significant association between the fathers' educational level and the presence of obesity or overweight in children ($P = 0.325$). Similarly, no significant link was found between the mothers' educational level and childhood obesity or overweight ($P = 0.800$). The mother's employment status did not significantly correlate with the presence of obesity or overweight in the children ($P = 0.500$), though a lower prevalence of obesity and overweight was noted among working mothers. Parental obesity was not statistically associated with childhood obesity or overweight ($P = 0.800$), and a family history of obesity or Type 2 diabetes also showed no significant correlation with these conditions in children ($P = 0.450$).
Conclusion
Addressing the root causes of obesity and overweight in childhood, particularly through understanding and addressing parental influence, is critical to reversing this growing epidemic.

Evaluation of the role of statins in the development of myalgias

Sabbagh Ghada[1], Imen Halloul[1], Rihab Khochtali[1], Taieb Ach[1], Wiem Saafi[1], Hamza Elfekih[1], Ghada Saad[1] & Yosra Hasni[1]
[1]Endocrinology and Diabetology Department, Farhat Hached University Hospital, Sousse, Tunisia, Endocrinology and Diabetology Department, Sousse, Tunisia

Introduction
Statins, widely used for cardiovascular prevention, are sometimes associated with muscle-related side effects, such as myalgias, which can lead to discontinuation of treatment. These side effects pose a challenge in therapeutic management. The objective of this study was to assess the role of statins in the onset of myalgias.
Methods
This cross-sectional descriptive study was conducted in November 2024 in the endocrinology department at Farhat Hached Hospital. Patients on statin therapy were included and evaluated using a questionnaire to define a Clinical Myalgia Index (CMI). A score between 9 and 11 indicated probable involvement, 7 to 8 suggested possible involvement, and a score below 7 indicated unlikely involvement.
Results
A total of 31 patients (mean age 60 $\pm$ 10 years, 71% female) were included. The prescribed statins were atorvastatin (83.9%), rosuvastatin (9.7%), and simvastatin (6.5%) at average doses of 40 mg, 20 mg, and 20 mg, respectively. A treatment duration of over 12 months was reported for 67% of the patients. Probable involvement was observed in 6.5%, possible involvement in 19.4%, and unlikely involvement in 74.2%. No significant association was found between the type or dose of statin, the indication for prescription, and the CMI. However, a treatment duration of less than 12 months increased the risk of myalgias by a factor of 6 ($P = 0.034$).
Conclusion
These findings highlight the importance of regular monitoring of myalgias in patients on statin therapy. They suggest that the risk of myalgia is higher during the first months of treatment, while the type or dose of statin does not significantly affect the likelihood of developing myalgias.

JOINT1511

Pro-oxidant-antioxidant system in patients with chronic kidney disease and type 2 diabetes mellitus in obese and non-obese patients

Andriy Nesen[1], Vira Zlatkina[2] & Polina Semenovikh[1]
[1]L.T. Malaya National Institute of Therapy National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine; [2]V. N. Karazin Kharkiv National University, Internal Medicine, Kharkiv, Ukraine

Introduction
Chronic kidney disease (CKD) is a major driver of mortality in patients with type 2 diabetes mellitus (t2DM). CKD is estimated to affect 50 % patients with DM. An increasing number of studies find obesity and t2DM a continuous progression of CKD in patients with and the development of cardiovascular complications.
Purpose
To estimate the pro-oxidant and antioxidant system state, to identify the presence of dependence on lipid profiles in patients with CKD and t2DM in obese and non-obese patients. It was observed 79 diabetic individuals with CKD, which were categorized into two groups: obese and non-obese, according to their body mass index (BMI). Group 1 ($n = 35$) patients with obesity (BMI$\geq$30 kg/m^2), group 2 ($n = 44$) non-obese patients. Healthy individuals ($n = 21$) - control group. We examined the state of the pro-oxidant-antioxidant balance (PAB) - total hydroperoxides (TH)/total antioxidant activity (TAA). Also, lipid profiles were investigated.
Results
In patients with with CKD and t2DM was found expression of PAB ($P < 0.05$) - decrease in TAA and an increase in TH, with more pronounced indicators been found in obese diabetic patients ($P = 0.01$); Studying lipid profiles, there were significantly increased proatherogenic lipoproteins (LDL-C, TC, TG) ($P < 0.05$) in obese and non-obese patients compared with healthy individuals. When comparing obese and non-obese patients, a more significant increase in pro-atherogenic lipid fractions was found in obese individuals ($P = 0.03$). Exploring the relationship between PAB and pro-atherogenic lipid fractions in obese patients with CKD and t2DM, a positive correlation was confirmed ($r = 0.45$) and ($r = 0.55$), $P < 0.05$, testifying an association between oxidative stress parameters and hyperlipidemia. It appears that it may be connected with increased lipid peroxidation and, as a result, atherosclerosis progression.
Conclusions
In patients with CKD and t2DM with obesity, a more pronounced imbalance of the pro-oxidant-antioxidant system, increased proatherogenic lipid levels were determined compared to non-obese patients with CKD and t2DM. These results clarify a clear relationship between lipid profiles and oxidative stress parameters in patients with obesity, CKD and t2DM, which may indicate that metabolic disorders - obesity are one of the leading risk factors for the progression of diabetic kidney disease.

Biomarkers of iron status and inflammation in Belgian children with overweight and obesity

Astrid De Wolf[1], Jean De Schepper[2], Elise Nauwynck[2], Jesse Vanbesien[2], Koen Huysentruyt[3], Sophie Bravo[4], Deborah De Geyter[5], Ellen Anckaert[5], Inge Gies[2] & Willem Staels[2]
[1]UZ Brussel, Department of Pediatrics, Brussels, Belgium; [2]UZ Brussel, Division of pediatric endocrinology, Brussels, Belgium; [3]UZ Brussel, Division of pediatric gastroenterology and nutrition, Brussels, Belgium;

[4]UZ Brussel, Division of pediatric hematology, Brussels, Belgium; [5]UZ Brussel, Department of clinical chemistry, Brussels, Belgium

Background
Obesity is a recognized risk factor for iron deficiency. Low-grade inflammation associated with obesity contributes to alterations in biomarkers of iron status. This study aimed to identify the best markers of adiposity and inflammation in relation to transferrin saturation (TS) and serum ferritin in a cohort of Belgian children and adolescents with overweight and obesity.
Methods
Data were retrieved from the medical records of 197 children with overweight/-obesity at the start of a weight loss program. Iron status was assessed through measurements of serum iron, transferrin, TS, and ferritin. Inflammatory markers included serum high-sensitivity C-reactive protein (hS CRP) and plasma fibrinogen. Adiposity was evaluated using BMI SDS, waist circumference (WC) SDS, subscapular skinfold thickness (SST) SDS, waist-to-height Ratio (WHR), and body fat percentage (BF) by bioelectrical impedance analysis (BIA). TS was calculated as iron (µg/dl) *100)/ (transferrin (g/l)* 127). Serum iron, transferrin, and ferritin levels were measured using the Cobas 8000 C702 platform. Stepwise multiple regression analysis was performed with TS and serum ferritin as dependent variables.
Results
Among the participants, 56% were male, 41% were prepubertal, and 80% had obesity (BMI SDS $>$ 2). The median (Q1, Q4) age was 12.0 (10.5, 13.8) years, BMI SDS 2.3 (2.0, 2.6), WC SDS 2.2 (1.9, 2.4), SST SDS 2.0 (1.8, 2.2), BF 34% (32,39), WHR 0.57 (0.53, 0.60), serum iron 65 µg/dl (52, 88), TS 18% (14, 18), and plasma ferritin 44µg/l(30,71). Iron deficiency, defined as TS $<$ 16%, was observed in 33.5 %, while 1.5 % had a low iron reserve, defined as a serum ferritin ($<$ 7 µg/l). Elevated TS ($>$ 45%) was rare ($<$ 0.5%), as was increased serum ferritin ($>$ 140 µg/l,1.5%). TS was not associated with gender, age, or pubertal status but positively correlated with ferritin (Rho = 0.33; $P < 0.001$). In regression analyses, WC SDS ($P = 0.01$) and hS CRP ($P = 0.03$) were the primary predictors of TS, while fibrinogen was the sole predictor of serum ferritin ($P = 0.04$).
Conclusion
Iron deficiency, defined by low TS, affects one-third of Belgian children and adolescents with overweight/obesity. Waist circumference and hS CRP emerged as the key predictors of low TS, while elevated fibrinogen correlated best with increased serum ferritin. These findings underscore the importance of assessing low-grade inflammation when evaluating iron status among this population.

Relationship between eating behavior of children with their nutritional status based on their bmi among 6 -12 year children: a mixed method study

Sarthak Das[1], Archana Malik[1], Vinayagamoorty V[1], Md Ehtesham Ansari[1] & Saurabh Varshney[1]
[1]All India Institute of Medical Sciences, Deoghar, Deoghar, India

Background
Childhood Obesity presents a global pandemic and stands as a significant impending threat to public health. With 380 million children and adolescents affected worldwide. A meta-analysis spanning from 2003 to 2023, encompassing 1,86,901 children in India, revealed that childhood obesity prevails at a pooled prevalence of 8.4%, while childhood overweight stands at 12.4%. We sought to explore the connection between eating behaviors and the risk of childhood obesity.
Objective
To Estimate the prevalence of obesity and determine the association between child eating behaviors and BMI.
Methods
A cross-sectional study was conducted inDeoghar a district of Jharkhand, India, a developing urban area in Sabah, involving 484 children aged 6–12 years. Participants were recruited from five primary schools selected using a combination of multistage stratified and convenience sampling methods. Data collection included sociodemographic details, anthropometric measurements of both parents and children, and children's eating behaviors, assessed using the Children Eating Behaviour Questionnaire (CEBQ). Age-adjusted BMI z-scores were calculated following the World Health Organization guidelines to evaluate nutritional status. A qualitative analysis was conducted through focused group discussions with parents of obese children. The feeding behaviors identified were then compared between the quantitative and qualitative analyses.
Results
The prevalence of childhood obesity among children aged 6–12 years is 13.2%. Analysis of the 'Food Approach' subscales from the CEBQ revealed higher mean scores in the overweight and obese groups compared to the normal-weight group. Conversely, the 'Food Avoidance' subscales showed lower mean scores in the overweight and obese groups compared to the normal-weight group. Very similar findings were observed in the qualitative analysis.
Conclusion
This study highlights that childhood obesity remains a significant health concern in a developing rural area of Jharkhand, India, as the "Food Approach" subscales were found to be positively associated with excess weight in children.

Premature aging in (young) adults with prader-willi syndrome

Janneke Baan[1,2], Marijn van Garderen[1,3], Francesco Mattace Raso[2], Layal Chaker[1] & Laura De Graaff[1,4]
[1]Erasmus Medical Center, Internal medicine Division of Endocrinology, Rotterdam, Netherlands; [2]Erasmus Medical Center, Geriatrics, Rotterdam, Netherlands; [3]University of Groningen, University Medical Center Groningen, Genetics, Groningen, Netherlands; [4]Radboud University Medical Center, Internal medicine Division of Endocrinology, Nijmegen, Netherlands

Introduction
In the Dutch Center of Reference for Prader-Willi syndrome (PWS), we follow over 200 adults with PWS. The majority shows clinical signs of premature aging, starting from the age of 25y. This is in line with the literature, reporting higher prevalences of functional impairment, as well as higher morbidity, higher overall mortality and premature brain aging. Little has been published about dementia in PWS, although some case reports have described dementia in relatively young patients. At cellular level, a significantly shorter leukocyte telomere length (a marker of biological age) has been described in PWS. We have performed a systematic review in order to provide a comprehensive overview of premature aging in PWS, with the aim to develop a PWS-specific geriatric aging score.
Methods
Systematic review (search strategy available upon request) focusing on age related conditions that, in the general population, mainly occur among the people aged 60 or up. Articles about vascular disorders, diabetes mellitus, chronic pulmonary disease, neoplasms including urinary, lung, breast, colorectal and prostatic cancers, cataract and macular degeneration, presbycusis, disorders in de digestive system, rheumatic diseases, prostate diseases and neurodegenerative disorders were included. Also, more specific aging terms like frailty, premature aging, falling, functional decline, dementia, Alzheimer, polypharmacy, osteoporosis, mobility limitation and multimorbidity were included.
Results
The systematic review is currently in progress. We will present a comprehensive overview of key indicators of premature aging, including prevalence of functional decline, metabolic disorders, neurodegenerative conditions, and other geriatric syndromes. Additionally, we will propose a PWS-specific geriatric aging score based on the collected data. These findings aim to enhance our understanding of premature aging in PWS and contribute to improved clinical care strategies for this population.
Conclusion
PWS is characterized by premature aging, starting from the age of 25. Based on our systematic review, we will provide an overview of age related disorders in the Prader-Willi population. We will present a PWS-specific geriatric aging score, which will help us quantify and understand (and in the future possibly prevent) premature aging in PWS.

The relationship between serum galectin-3 level and echocardiographic findings in patients with polycystic ovary syndrome

Ibrahim Erdem[1], Huseyin Ali Ozturk[2], Erdinc Gulumsek[2] & Hilmi Erdem Sumbul[2]
[1]Department of Internal Medicine, Viransehir State Hospital, Sanliurfa, Turkey, Sanliurfa, Türkiye; [2]Department of Internal Medicine, University of Health Sciences - Adana Health Practice and Research Center, Adana, Turkey, Adana, Türkiye

Aim
The study aimed to examine the relationship between serum galectin-3 level in the type with polycystic ovary syndrome (PCOS) and global longitudinal strain (GLS) and aortic intima-media thickness (A-IMT) and whether these measurements are a marker for detecting measurements in the early stages of atherosclerosis and heart failure.

Methods
A total of 80 participants, 40 newly diagnosed PCOS patients and 40 healthy control groups, were included in the Health Sciences University Adana City Training and Research Hospital between 01.06.2021 and 31.03.2022. Galectin-3 level was measured by using Human galectin-3 kits and Enzyme-Linked Immuno Sorbent Assay method. A-IMT and GLS measurements were performed by using ultrasonography and echocardiography.
Results
When both study groups were evaluated, a statistically significant difference was found between the groups in terms of blood glucose, HOMA-IR Index, galectin-3, A-IMT, and GLS values. A correlation analysis was carried out between galectin-3 level and other demographic, clinical and laboratory parameters in the PCOS patient group and control group. Parameters related to Galectin-3 level; GLS were found as A-IMT and HOMA-IR Index. Linear regression analysis was performed using parameters that showed significant correlation with Galectin-3 level. Galectin-3 level was found to be independently associated with GLS.
Conclusion
The study shows that the galectin-3 molecule can be said to detect long-term outcomes such as atherosclerosis and heart failure in a more subclinical period in PCOS patients and that it can help identify the risky patient population, and can be used as a biomarker in diagnosis and follow-up. .
Keywords
Aortic intima-media thickness, galectin-3, global longitudinal strain, polycystic ovary syndrome.

Impact of obesity management during polycystic ovary syndrome in young adolescents (experience of a specialized pediatric endocrinology consultation)
Nihad Selim[1], Foued Abdelaziz, Ahmed Boustil[1], Hasna Sehab[1], Yahia Chebini[1] & Nadira Bouchair[1]
[1]Saint Therese Clinic, University Hospital of Annaba, Pediatrics, Annaba, Algeria

Introduction
Polycystic ovary syndrome (PCOS) is due to a hormonal imbalance of ovarian or central origin, it leads to excessive androgen production, it is responsible for 10% of fertility disorders in women of childbearing age but it can appear earlier in adolescents, it clinically results in cycle disorders, signs of hyperandrogenism, metabolic disorders related to insulin resistance, which is itself secondary to hyperandrogenism with obesity and risk of T2D and later metabolic complications (hypertension, cardiovascular diseases), radiologically it results in polycystic dystrophic ovaries. There is no specific treatment, it is essentially symptomatic, it should be noted that lifestyle plays an important role in the balance of the disease, a 10% decrease in weight could reduce the signs of hyperandrogenism and its complications with the improvement of cycle and fertility disorders.
Material and Methods
In our consultation, we collected 8 adolescent girls with PCOS.
Results
The age of our patients is between 13 and 16 years old, the main reason for consultation was cycle disorders (spaniomenorrhea and sometimes secondary amenorrhea), 6 had obesity to varying degrees, all the patients had signs of hyperandrogenism such as hirsutism, acne, hair loss, etc., 4 had T2D and 7 had a history of cycle disorders in the context of obesity with or without fertility disorders in the mother, the aunts and the cousins. The patients had received different treatments depending on the situation (Dydrogesterone, metformin, hormonal treatment, gynecological advice and lifestyle management). In the 6 patients who managed to reduce their weight, we noted an improvement in cycle disorders with a decrease in signs of hyperandrogenism.
Conclusions
PCOS is a multifactorial pathology where lifestyle and weight management significantly improve the clinical signs in these adolescent girls while remaining cautious about fertility disorders in the future.

JOINT149
Pharmacological approach to neonatal hyperbilirubinemia
Kiumars Pirkalani[1,2]
[1]Mehr Medical Group, Internal Medicine, Tehran, Iran; [2]Mehr Medical Group, Internal Medicien, Tehran, Iran

Background
A very conceptual and uncomprehensive point in the strategy is that chelation of Bilirubin is not as easy as conjugation. It is bound to albumin within the circulation and soluble in fat. Besides, in contrast to general notion the lipophilic site of the molecule is not where conjugation occurs. Conjugation does not cover the fat-soluble side of the molecule but makes the molecule larger and more ware soluble from the water soluble pole. So, it is difficult to approach the molecule with solubilizing agents from the fat-soluble site because chelating agents are themselves water soluble. The only hope would be extraction of Bilirubin from albumin in the circulation and increasing the binding potential of albumin to extract bilirubin from fat rich tissues like the brain.
Aim
Increasing the “Albumin pool” to extract more unconjugated Bilirubin from fat rich tissues and hence therapeutic and prophylactic reduction of unconjugated bilirubin.
Methods
Twelve neonates with harmless hyperbilirubinemia in the range of 8mg/dl were treated with a single dose 500mg of a triguanide derivative called TR-225. Bilirubin was measured every half hour for 24 hours. Patients with stable levels under 2 were discharged from the hospital.
Results
TR-225 is 100% capable of reducing hyperbilirubinemia in all patients studied. The conjugate could be traced within the urine in a proportional manner. Speed of bilirubin reduction is 18 times that of exchange transfusion. The time/-concentration curve denotes extreme effectiveness without rebound due to re-distribution of bilirubin from peripheral fat to circulation. The treatment is not without side effects and can hardly be used as a prophylaxis.
Conclusion
Treatment of neonatal hyperbilirubinemia with a chelator is chemically extremely difficult and needs sophisticated drug development techniques such as artificial intelligence. But it is a very interesting issue which can possibly close thousands of neonatal wards worldwide.

JOINT3706
Beyond weight: the quality of life in young women living with obesity
Piterschi Carolina[1]
[1]Nicolae Testemitanu State University of Medicine and Pharmacy, Department of endocrinology, Chi?inău, Moldova

Introduction
Obesity is a significant global health issue and an independent risk factor for numerous chronic physical and mental health conditions. Beyond its medical implications, obesity also affects quality of life, influencing physical well-being, psychological health, social interactions, and life satisfaction. Individuals with obesity often experience limitations in daily activities, reduced mobility, emotional distress, and stigma, all of which contribute to a diminished sense of well-being. This study aimed to assess the impact of obesity on various health outcomes and to measure the health-related quality of life (HRQoL) in young women with obesity.
Material and Methods
A total of 130 young women, aged 18-45, were included in the study. Participants were categorized into two groups based on BMI: 69 women with obesity (BMI $\geq$30 kg/m^2) and 61 with normal weight (BMI $\leq$25 kg/m^2). HRQoL was measured using the 36-item Short-Form Health Survey (SF-36). Pearson correlation coefficients were used to examine associations between obesity and HRQoL domains, controlling for potential confounding factors.
Results
The mean age was 31.8 $\pm$ 6.75 years, with no significant difference between groups. The results reveal a significant negative correlation between between BMI and multiple HRQoL domains in young women, including physical functioning ($F=62.89$, $P<0.001$), emotional well-being ($F=68.47$, $P<0.001$), social functioning ($F=70.9$, $P<0.001$), and general health ($F=78.96$, $P<0.001$). Women with obesity reported increased role limitations due to physical ($F=28.37$, $P<0.001$) and emotional factors ($F=46.33$, $P<0.001$), reduced vitality ($F=72.7$, $P<0.001$), and greater bodily pain ($F=59.17$, $P<0.001$). The findings indicate that as BMI increases, perceived quality of life significantly declines, particularly in mental and social health aspects.
Conclusion
This study highlights the strong association between obesity and reduced HRQoL in young women, particularly in emotional well-being, social participation, and physical functioning. Given these findings, comprehensive, multidisciplinary

interventions that integrate mental health support, customized physical activity programs, and social empowerment strategies are essential for enhancing the overall well-being of young women living with obesity.

Impact of B vitamin intake on weight loss outcomes in obese patients

Sana Khamassi[1], Fatma Boukhayatia[1], Haifa Abdesselem[1], Emna Bornaz[1], Nesrine Dhieb[2], Kamilia Ounaissa[1], Sana Hammami[3], Houda Bouhajja[4], Amel Gammoudi[2], Awatef Kacem[2], Emna Talbi[4], Jamoussi Henda[2] & Chiraz Amrouche[1]

[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology, Obesity Reserach Unit, Tunis, Tunisia; [3]National Institute of Nutrition and Food Technology, Clinical Biology Laboratory, Tunis, Tunisia; [4]National Institute of Nutrition and Food Technology, UR17SP01-Clinical Biology Laboratory, Tunis, Tunisia

Background

Recent research has increasingly focused on the relationship between B vitamin intake and weight loss outcomes in obese individuals undergoing weight loss interventions. Numerous studies have examined how different B vitamins affect obesity-related factors, including body fat distribution and metabolic processes [1]. The aim of our study was to assess the impact of baseline B vitamin intake on weight loss outcomes in obese patients.

Methods

We conducted a longitudinal study involving 100 obese adult patients over 6 months. We analyzed body composition using SECA MBCA 515 bioimpedance at baseline and at follow-up. dietary survey data were collected at baseline using Nutrilog software. A balanced hypocaloric diet was prescribed and patients received regular follow-ups.

Results

The mean age was 44.42 ± 13.25 years and the sex ratio (M/F) was 0.11. The mean fat mass (FM) and fat mass index (FMI) values were 52.50 ± 12.39kg and 19.74 ± 4.03kg/m^2, respectively. The mean fat-free mass index (FFMI) was 20.34 ± 2.53kg/m^2 and 20% of the participants had a below-average FFMI at baseline. The deficiencies in vitamin B group intake observed at baseline were dominated by a deficiency in vitamin B9 (44%) and vitamin B2 (36%). At 6 month,22 patients were lost to follow-up and 78 patients completed the study with a mean body weight loss of 4.13 ± 6.90 %.The intake of vitamin B12 at baseline was positively correlated with the loss in BMI ($P = 0.009$), waist circumference ($P = 0.009$), and fat mass ($P = 0.007$), and inversely correlated with the loss in lean mass ($P < 0.001$). In contrast, the intakes of vitamins B6 and B9 were inversely correlated with the loss of fat-free mass ($P = 0.04$ and 0.041, respectively), skeletal muscle mass ($P = 0.038$ and $P = 0.011$, respectively), and appendicular muscle mass ($P = 0.021$ and $P = 0.024$, respectively). However, the intake of vitamins B1, B2, B3, and B5 did not show any correlation with the different parameters of weight loss.

Conclusion

Our study underscores the importance of considering vitamin B intake, particularly B12, B6, and B9, when prescribing dietary interventions for weight loss in obese patients. Addressing potential deficiencies in these vitamins could enhance the effectiveness of weight loss strategies.

JOINT1351

Regional prevalence of underweight, overweight and obesity in adults from 1999 to 2023 at their first endocrinological examination: a retrospective cross-sectional study performed in liguria, italy

Massimo Giusti[1]

[1]Endocrine Unit, Centro Clinico Diagnostico Priamar, Savona, Italy

Background

Combined burden of underweight and obesity has increased in most countries. No studies of this phenomenon in Liguria have been published.

Aim

To evaluate the prevalence of underweight, overweight and obesity in Caucasian male (M) and female (F) adults undergoing their first endocrinological examination in the district of Savona.

Methods

From 1999 to 2023, 6868 records (1317M; 5551F) were evaluated. Age, BMI, reason for examination and current dietary habit were evaluated. Records were grouped into five 5-year periods. Underweight was defined as BMI < 18.5 kg/m^2 and obesity as BMI ≥ 30.0 kg/m^2. Individuals with a BMI of 18.5-24.9 kg/m^2 and 25.0-29.9 kg/m^2 were classified as being of normal weight and overweight. The prevalence of each BMI interval in each period was evaluated.

Results.

A significant ($P < 0.001$) increase in age was observed from the 1999-2003 period to the 2019-2023 period and a significant ($P < 0.001$) positive correlation was noted between age and BMI in both genders. In M, the median prevalence of underweight decreased slightly from 1.8% in the period 1999-2003 to 0.8% in 2019-2023. In F, the prevalence of underweight did not change significantly (median 3.7%, 1999-2003). The median prevalence of overweight was 40.7% (2009-2013) in M and 26.1% (2004-2008) in F, declining (2004-2008 *vs* 2019-2023) minimally in F (-0.8%) and more evidently in M (-9.0%). Overweight and obesity displayed a median prevalence of 63.4% in M (2014-2018) and 47.2% in F (2009-2013). Normal weight showed a median prevalence of 35.2% in M (1999-2003) and 48.3% in F (2014-2018). Regarding reasons for the first examination, weight and/or metabolic diseases showed a median prevalence of 10.2% in both genders. The prevalence of dietary intervention owing to underweight or overweight/obesity increased from 5.6% to 18.2% in M and from 14.4% to 18.4% in F over the 25 years.

Limitations

Subjects were not representative of the general population of our district. Our results cannot therefore be extrapolated to regional or national populations. Moreover, relatively few subjects, especially males, were involved.

Conclusions

Our study involved about 2% of the population of the Savona district. Less than 50% of subjects were of normal weight. Overweight and obesity affected a large part of the population, but their prevalence did not change significantly over 25 years. Subjects undergoing examination showed limited awareness of this condition. The greatest change in BMI was age-dependent in both genders. The slight increase in subjects who reported controlling their diet is encouraging.

Evaluation of childhood obesity management in primary care setting

Mouna Elleuch[1], Fatma Lachtar[1], Hamdi Frikha[1], Zaineb Fourati[1], Yosra Majdoub[2], Yassmine Abdelkafi[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]

[1]Hedi Chaker University Hospital, Endocrinology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Preventive & Community Medicine, Sfax, Tunisia

Introduction

Childhood obesity (CO) is a major public health concern in the post-industrial era. The absence of specialized management structures or the difficulty in accessing them means that family physicians (FPs) are frequently confronted with this condition. The aim of this study is to assess the diagnostic and therapeutic approaches of FPs in managing CO.

Methods

We conducted a cross-sectional descriptive study in 2024, including FPs practicing in southern Tunisia. The study was conducted online and through direct interviews with the participating physicians. The target population for the questionnaire consisted of children under 18 years old with a BMI > 2 SD.

Results

A total of 100 participants were included, with a mean age of 48.5 ± 11 years and a female predominance (64%). The majority of the surveyed FPs (68%) had more than 10 years of clinical experience. Public sector physicians and those practicing in urban areas accounted for 59% and 52% of respondents, respectively. The evaluation practices for CO were characterized by the systematic calculation of BMI and dietary assessment in only 5% and 30% of FPs, respectively. The impact of CO was assessed by only 10% of practitioners. The main barriers reported by FPs included workload (25%) and insufficient theoretical training (35%). Management practices were primarily based on non-personalized dietary recommendations (75%) and encouragement of physical activity (55%). Most children with CO were referred to specialists, particularly adult endocrinologists (68%).

Conclusion

FPs frequently face the challenge of childhood obesity. However, its management presents several limitations in this sector, particularly regarding screening, standardized anthropometric evaluation, and dietary or potential pharmacological interventions. These limitations can be attributed to gaps in initial training, the absence of collaborative care networks, and constraints related to time and workload.

Significance of liver enzyme assessment in women with metabolic dysfunction-associated liver disease, obesity, newly diagnosed type 2 diabetes, and hypertension

Ilona Rudnieva[1]
[1]Bogomolets Medical University, Kyiv, Ukraine

Background and Objectives
Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading chronic liver condition globally, affecting individuals across various ages and ethnicities. It strongly correlates with obesity (over 70% of metabolic-associated steatohepatitis [MASH] cases occur in obese individuals), type 2 diabetes mellitus (T2DM; nearly 75% of MASH patients have T2DM), hyperlipidemia (20–80% show elevated cholesterol and triglycerides), and atherosclerosis. Since metabolic dysfunction is a cornerstone of MASLD, its diagnosis necessitates confirmation of hepatic steatosis alongside at least one of five cardiometabolic risk factors. Early detection of MASLD, especially in individuals with excess weight or obesity, through liver enzyme evaluation (alanine aminotransferase [ALT], gamma-glutamyl transpeptidase [GGT], and aspartate aminotransferase [AST]), and fibrosis assessment—coupled with prompt treatment and risk factor management—can curb disease progression and associated complications, while reducing socio-economic burdens.
Methods
The study involved 36 women, aged 24–64 years, with body mass indices (BMI) ranging from 30.5 to 69.8 kg/m^2, all scheduled for bariatric surgery. They underwent screening for MASH through clinical assessments, including blood tests to measure ALT, AST, and GGT levels, as well as hemoglobin A1c (HbA1c). Selection criteria prioritized elevated ALT levels, ALT/AST ratios below 1, and raised GGT levels. HbA1c levels above 6.5% confirmed diabetes mellitus. Liver enzyme levels were determined via colorimetric biochemical methods, while HbA1c was measured using high-performance liquid chromatography. Blood pressure (BP) was recorded in the seated position using a mercury sphygmomanometer. Hepatic steatosis was graded using ultrasound steatometry.
Results
MASLD was diagnosed in all participants. MASH was identified in 39%, with steatosis categorized as S1 in 21%, S2 in 50%, and S3 in 77.8% of cases. Elevated ALT, AST, and GGT levels were noted in 11% of patients with BP exceeding 140/90 mm Hg. HbA1c levels $>6.5\%$ alongside increased liver enzymes were seen in 6% of cases. Simultaneous elevations in ALT, AST, GGT, HbA1c, and BP $>140/90$ mm Hg occurred in 6% of patients.
Conclusions
MASLD was detected in all obese participants, regardless of T2DM or hypertension status. MASH was most prevalent among women with advanced steatosis (S3; 77.8%). Women with obesity and hypertension had a higher occurrence of MASH (11%) compared to those with obesity and T2DM (6%) or both conditions combined (6%).

Demographic, hereditary, and environmental factors in the development of masld among type 2 diabetes mellitus patients

Yesmine Elloumi[1], Mouna Elleuch[1], Khouloud Boujelben[1], Med Khairi Arous[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Mejdoub Rekik[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
The development of Metabolic Associated Steatotic Liver Disease (MASLD) in patients with type 2 diabetes mellitus (T2DM) is influenced by a complex interplay of demographic, hereditary, and environmental factors. Understanding these factors is essential for identifying high-risk individuals and improving prevention strategies. We aim to explore specific demographic characteristics, family history, and environmental exposures that contribute to the onset of MASLD in T2DM patients.
Methods
A retrospective study including 202 T2DM patients, followed from 2012 to 2024 at the Endocrinology-Diabetology Department of Hedi Chaker University Hospital in Sfax, Tunisia was conducted. Patients were divided into two groups: Group1 comprised 101 diabetic patients with MASLD while Group2 comprised 101 patients without MASLD.
Results
Demographic factors did not significantly influence the development of steatotic lesions, as both patient groups (Group1 and Group2) shared similar characteristics in terms of age (55 [45-66] years vs. 59 [49-68] years, respectively; $P = 0.087$) and gender ($P = 0.773$). Likewise, a family history of cardio-metabolic diseases was not strongly associated with the onset of MASLD, whether it involved early cardiovascular events ($P = 0.949$), family history of hypertension ($P = 0.272$), or dyslipidemia ($P = 0.239$). However, a family history of autoimmune diseases emerged as a significant risk factor for MASLD ($P = 0.020$). Interestingly, lifestyle factors such as smoking, occasional alcohol consumption, and physical inactivity did not appear to promote steatosis in this cohort ($P = 0.525$, $P = 0.485$, $P = 0.310$, respectively).
Conclusion
These findings suggest that autoimmune history may play a key role in the development of MASLD.

A resource for practical food portions for children and adults with prader-willi syndrome

Evelien Gevers[1,2], Chris Smith[3], Lisa Singh[4], Jennifer Sanderson[5], Jackie Lodge[6], Peri Wallach Lamont[7] & Jenni Henderson[8]
[1]Barts Health NHS Trust - Royal London Children's Hospital, Paediatric Endocrinology, London, United Kingdom; [2]Barts and the London School of Medicine, Queen Mary University of London, Center for Endocrinology, London, United Kingdom; [3]Princess Alexandra Hospital, Department of Dietetics, Bristol, United Kingdom; [4]NHS Greater Glasglow and Clyde, Department of Paediatric Dietetics, Glasglow, United Kingdom; [5]NHS Greater Glasglow and Clyde, Department of Paediatric Endocrinology, Glasglow, United Kingdom; [6]Prader Willi Syndrome Association UK, Northampton, United Kingdom; [7]Royal London Hospital, Department of Paediatrics, Glasgow, United Kingdom; [8]National Diet Resources, Glasgow, United Kingdom

Introduction
Reducing calorie intake to avoid excessive weight gain whilst maintaining nutrient intake and growth is challenging in the management of PWS. General societal misconception of appropriate food portions also impacts care. Guidelines suggest 30% fewer calories are required in PWS, whereas micronutrient requirement is unchanged. No visual, practical guide exists to illustrate such appropriate food portion sizes. We aimed to 1. develop a national pictorial resource defining and illustrating correct portion sizes for children and adults with PWS, and 2. to assess the nutritional adequacy of these proposed portions.
Methods
A national working group with experience in PWS was devised (paediatric endocrinologist, specialist dieticians, therapy assistant, representative from the PWS Association UK and an endocrinology nurse) and linked with Nutrition and Diet Resources UK, a charity who develop nutritional resources. Previously defined national portion sizes for children (Public Health England, 2016) were proportionally reduced by 30% for a selection of commonly consumed foods for 6 age categories (2-3/4-6/7-10/11-13/14-18/19-64 years) and photographs produced. Recommended number of portions of each food group per day were defined from national recommendations, allowing for the development of day meal plans. Patient groups were consulted to include parent/patient feedback. A final resource was recirculated to the patient groups and national stakeholders for peer review. An example proposed 24 hour intake from the resource underwent dietary analysis for each age group for both sexes to validate nutritional adequacy.
Results
Sixty common foods were used to calculate age specific food portions and 348 photographs were taken to produce the resource (https://www.pwsa.co.uk/practicalportions). Less healthy foods were included but highlighted as undesired. Examples of 24 hour intake for each age group were analysed for nutritional value. Caloric intake ranged from 49% (adult males) to 69% (5 year old females) of the EAR. Several micronutrients were lower than recommended in several age groups including iron, zinc and iodine.
Conclusion
Poorly defined dietary guidance in PWS can negatively impact acute and chronic health outcomes. In addition, such an unusual recommended intake can be difficult to define, appreciate and apply. We present a PWS unique resource to provide correct food portion sizes and practically support and address these challenges. Nutritional analysis supports its use to provide a caloric intake suitable for PWS and highlights micronutrients that may require attention. Strengths include user involvement and visual nature reducing language barriers, allowing wide application. Limitations include restriction to 60 foods.

JOINT2658

Severe hypertriglyceridemia in an infant during COVID-19 episode: case report

Jessika Alves[1], Isabela Maeoka[1], Carolina Bantle[1], Mateus Vargas[1] & Alexandre Jose Carrilho[1]
[1]State University of Londrina, Internal Medicine, Londrina, Brazil

Familial chylomicronemia syndrome (FFS) is a severe form of dyslipidemia resulting from the loss of function of the enzyme lipoprotein lipase (LPL) or one of its cofactors, such as apolipoprotein A5 (apo A5) or apolipoprotein C-II (apo CII). It is a rare disease, with an estimated prevalence of 1:1,000,000 and important implications for the health of affected individuals. We describe the case of an infant who presented manifestations of the disease at 4 months of age, during a COVID-19 episode. The child was admitted to the hospital with fever and diarrhea. The laboratory investigation confirmed acute SARS-CoV-2 infection, liver steatosis and hepatomegaly, hypertriglyceridemia (triglycerides 9,394 mg/dl), hypercholesterolemia (total cholesterol 395 mg/dl) and elevated alanine and aspartate aminotransferases. Considering the risk of acute pancreatitis, breastfeeding was stopped, and the child was put on a special diet formula with 0% fat and supplemented with medium-chain triglycerides. After a week, the child was asymptomatic and repeated blood tests revealed a significant decrease in serum triglycerides (262 mg/dl) and total cholesterol (284 mg/dl). The child was discharged from the hospital and, during outpatient follow-up, maintained normal triglyceride levels during the transition to a normal diet. We performed a search for variants in the following gene: ATP-binding cassette transporter A1 (ABCA1), 1-Acylglycerol-3-Phosphate O-Acyltransferase 2 (AGPAT2), AKT Serina/Treonina Quinase 2 (AKT2), Apolipoprotein A5 (APOA5), Apolipoprotein C2 (APOC2), Berardinelli-Seip Congenital Lipodystrophy 2 (BSCL2), Caveolin 1 (CAV1), Caveolae Associated Protein 1 (CAVIN1), CF Transmembrane Conductance Regulator (CFTR), Cell Death Inducing DFFA Like Effector C (CIDEC), Chymotrypsin C (CTRC), Cytochrome P450 Family 27 Subfamily A member 1 (CYP27A1), Glycosylphosphatidylinositol Anchored High Density Lipoprotein Binding Protein 1 (GPIHBP1), Lysosomal Acid Lipase A (LIPA), Lipase E Hormone Sensitive Type (LIPE), Lipase Maturation Factor 1 (LMF1), Lamin A/C (LMNA), Lamin B2 (LMNB2), Lipoprotein Lipase (LPL), Mitofusin 2 (MFN2), Perilipin 1 (PLIN1), DNA Polymerase Delta 1, Catalytic Subunit (POLD1), Peroxisome Proliferator Activated Receptor Gamma (PPARG), Serine Protease 1 (PRSS1), Proteasome 20S Subunit Beta 8 (PSMB8), Sphingomyelin Phosphodiesterase 1 (SMPD1), Serine Peptidase Inhibitor Kazal Type 1 (SPINK1) and Zinc Metallopeptidase STE24 (ZMPSTE24). The results did not show any variant that could explain the phenotype, which led us to hypothesize that the transient severe hypertriglyceridemia was secondary to COVID-19 infection.

Recurrent hypoglycemia in persistent hypoglycemia hyperinsulinism of infancy post near total pancreatectomy

Deasy Fiasry[1], Rayi Kurnia Perwitasari[2], Yuni Hisbiyah[3], Nur Rochmah[3] & Muhammad Faizi[2]
[1]Airlangga University, Child Health, Soetomo Hospital, Surabaya, Indonesia; [2]RSUD Dr. Soetomo, Department of Pediatrics, Surabaya, Indonesia; [3]Universitas Airlangga, Department of Pediatrics, Surabaya, Indonesia

Background
The most common causes of persistent hypoglycemia Hyperinsulinism (PHHI) are genetic or congenital abnormalities in the regulation of insulin secretion, deficiencies in growth hormone and/or cortisol, or abnormalities in the metabolism of glucose, glycogen, and fatty acids. Congenital hyperinsulinism's prevalence: 1 in 2700 in some consanguineous populations; 1 in 28,000 to 50,000 live births in the general population. According to our committee's report, it can be difficult to identify neonates with PH issues because they can resemble transitional hypoglycemia within the first 48 hours. Furthermore, the first few months are crucial since 25% to 50% of children with congenital hyperinsulinism have developmental difficulties. For infants and young children, hypoglycemia is defined as blood glucose levels below 60 mg/dl/lthroughout the first 72 hours of life and beyond.
Case
This report aims to present a case of diffused type PHHI that was effectively treated with a near pancreatectomy and later identified with adrenal insufficiency. K, a 4-month-old girl, weight 5.9 kg, length 56 cm, was sent to Soetomo Hospital because she had hypoglycemia and frequent seizures since 3 days old. According to the family history, no member of family with diabetes. Ketone levels were 0.1 mmol/l,C.peptide levels were 3.3 ng/ml (1.1-4.4), lactate levels were 2.77 mmol/l(0.4-2.0), insulin levels were 16.8 µU/ml (4.04-23.46), FT4 levels were 1.63 ng/dl (0.9-1.75), TSH levels were 5.032 µIU/ml (0.64-6.27), GH levels were 1.35 ng/ml (0.14-6.27), cortisol levels were 1.8 µg/ml (45.5-208.2), taken when blood glucose 33 mg/dl. We evaluated a patient with wasting, adrenal insufficiency, and recurrent hypoglicemia. Due to the lack of diazoxide in Indonesia, the patient was treated with oral nifedipine (~2 mg/kg/day), SC octreotide (~5 mg/kg/day), and oral prednisone (~6 mg/kg/day), along with a glucose infusion rate up to 12 (formula milk added to IV fluids via a central line). After a month, the treatment failed, and we referred to pediatric surgery for pancreatectomy. Preoperative labs were normal, and abdominal CT showed no mass. We want to conduct a genetic test to determine the type of hypoglycemia, but the family refuses. Seven days post-pancreatectomy, the patient was ready for discharge but had morning hypoglycemia. We prescribed nifedipine 1 mg/kg/day orally to stabilize. Early recognition and treatment are crucial for preventing these sequelae.
Conclusion
Patients PHHI who cannot control their hypoglycemia with medication may need a near-total pancreatectomy; nevertheless, this could lead to diabetes mellitus or recurrent hypoglycemia after surgery.

Physical activity among the healthcare providers at ibn rochd university hospital in casablanca

Majda El Baidouri[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]CHU Ibn Rochd, Clinical Neurosciences and Mental Health Laboratory, Faculty of Medicine and Pharmacy, Hassan II University, Casablanca, Morocco, Department of Endocrinology, Metabolic Diseases, and Nutrition, Casablanca, Morocco

Introduction
Physical activity (PA) is a current public health topic. There is growing awareness of the health problems associated with sedentary behavior, highlighting the importance of creating supportive work environments.
Objective of The Study
Our survey aims to evaluate the practice of PA among the paramedical staff at Ibn Rochd University Hospital in Casablanca, identify constraints, and propose potential solutions.
Materials and Methods
A cross-sectional descriptive and analytical study conducted over 3 months, using the Global Physical Activity Questionnaire (GPAQ), analyzed with R, SPSS, and Epi-info software.
Results
Our study included 302 participants, the majority (72.2%) being nurses. The average age was 34.65 years ± 9.3 years (range 20-61 years) with a female-to-male sex ratio of 2.43. Most participants (56.57%) had a normal body mass index, 37.72% were overweight, and 6% were obese. The most common medical histories were diabetes (12%), dyslipidemia (10.5%), and hypertension (10.3%). Furthermore, 70.86% of participants engage in physical activity as part of their work, 70.86% during commuting, and 37.08% engage in recreational physical activity. The most frequent barriers were family (45.69%) and professional (42.05%) responsibilities. The study found a statistically significant association between physical activity and personal history of diabetes and dyslipidemia, the number of working days per week, and professional seniority.
Conclusion
Although the majority of participants were physically active, work conditions should be improved to overcome barriers preventing regular physical activity.

Bernard Courtois discovered iodine in 1811 while digesting algae, which resulted in the emission of purple vapor. Bernard Courtois identified iodine within the thyroid gland in 1895 and established in 1917 that iodine deficiency leads to thyroid gland enlargement. The kidneys eliminate over 90% of iodine. The study of iodine levels in twenty-four-hour urine, measured in µg per day, is acknowledged as an optimal approach for assessing the body's iodine status. This study aimed to investigate the dietary consumption of iodine and the urinary iodine content in young individuals. The study aimed to explore the correlation between urinary iodine content, muscle mass, and the speed of muscular response. Seventy participants aged 18 to 24 were involved, comprising 35 males and 35 females. The exclusion criteria included confirmed thyroid illness and disorders of iodine metabolism. The morning urine was tested, dietary iodine intake was evaluated, and muscle mass and response time were measured. The median iodine concentration in urine was 120.77 µg/l,and the estimated iodine consumption was 624.66 µg. The median muscle tissue percentage is 32.55%, while the median muscle reaction speed is 274.5 ms. The correlation between urinary iodine levels, muscle tissue (%), and muscle reaction speed was assessed. A notable, negative, and modest association between urinary iodine content and muscle reaction speed was identified (Rho = -0.289). Other relationships lack significance. The projected dietary iodine consumption of participants in this study exceeds the reference values established by the World Health Organization. The iodine concentration in the urine of the individuals participating in this study is within the reference levels. There is no correlation between the iodine concentration in urine and muscle mass among the studied population. The iodine concentration in urine within the studied population exhibits a substantial, negative, and modest correlation with reaction speed.

Key Words
iodine, muscles, time reactions.

Management of obesity and diabetes mellitus type 2 in psoriatic arthritis

Lambros Athanassiou[1], Panagiotis Athanassiou[2], Antonia Elezoglou[1] & Ifigenia Kostoglou-Athanassiou[3]
[1]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [2]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece; [3]Asclepeion Hospital, Voula, Department of Endocrinology, Diabetes and Metabolism, Athens, Greece

Psoriatic arthritis may be accompanied by psoriasis and is known to be associated with metabolic syndrome and obesity. Diabetes mellitus type 2 may also be observed. Psoriatic arthritis and psoriasis are currently successfully managed by the administration of biological agents. Obesity may necessitate dose modification in the case of treatment with biological agents. Additionally, psoriatic arthritis may lead to mobility limitation. Obesity may further limit mobility. Therefore, the successful management of obesity in patients with psoriatic arthritis is critical. The aim was to present a cohort of patients suffering from psoriatic arthritis, florid psoriasis, metabolic syndrome and obesity who were successfully managed by the administration of GLP-1 receptor agonists. A cohort of 6 patients, 2 female and 4 male, suffering from psoriatic arthritis and florid psoriasis, aged 38-56 years, is presented. Patients had overt metabolic syndrome with obesity and diabetes mellitus type 2. All patients received metformin when entering the study. GLP-1 receptor agonists were administered to these patients for a period of 6 months. The administration of GLP-1 receptor agonists to this group of patients suffering from psoriatic arthritis, florid psoriasis and obesity led to weight loss of 1.2 – 8.2 kg. In addition, psoriasis lesions improved. Blood glucose levels also improved. GLP-1 receptor agonists were subsequently administered for 6 more months to all patients. No significant adverse events were noted. In particular, the administration of GLP-1 receptor agonists in patients on treatment with biological agents seemed to improve quality of life. Obesity in the context of metabolic syndrome may complicate psoriatic arthritis and psoriasis. The successful management of obesity in these patients is critical as it improves mobility and prevents disability deterioration. GLP-1 receptor agonists appear ideal for the management of obesity and diabetes mellitus type 2 in patients with psoriatic arthritis.

Congenital hyperinsulinism: first 18F-DOPA PET/CT scan performed in kazakhstan

Ayazhan Abikenova[1], Marzhan Rakhimzhanova[1], Aigul Saduakasova[2] & Timur Sarsengaliyev[2]
[1]CF UMC, Astana, Kazakhstan; [2]Medical Center Hospital Office of Presidential Affairs Republic of Kazakhstan, Astana, Kazakhstan

Introduction
Congenital hyperinsulinism (CHI) is a rare but serious cause of persistent hypoglycemia in neonates and infants.
Case Report
This case report describes the diagnosis of CHI in a 1-month-old girl in Kazakhstan, marking the country's first use of an 18F-DOPA PET/CT scan for this condition. The patient was admitted to the endocrine unit with severe, persistent hypoglycemia and underwent further investigation. Historically, CHI diagnoses in Kazakhstan were based primarily on clinical and laboratory findings, as genetic testing and PET/CT scans were not available due to the unavailability of the 18F-DOPA isotope. This case highlights the successful use of 18F-DOPA PET/CT imaging, which helped identify the diffuse variant of CHI. Despite initial treatment with diazoxide, the patient's condition remained unstable, but she showed improvement with subcutaneous octreotide injections, which effectively stabilized her blood sugar levels.
Conclusions
This case represents the first use of 18F-DOPA PET/CT imaging in Kazakhstan for diagnosing congenital hyperinsulinism and underscores the importance of expanding access to advanced diagnostic tools and therapies in managing rare and complex endocrine disorders. Timely diagnosis and appropriate treatment are critical to improving patient outcomes in such cases.

Uncommon side effects of uncommon drug: hydroxychloroquine-induced hypoglycaemia in a patient with multisystem lupus

Naing Myo Aung[1], Lina Eltayieb[1], Furhana Hussein[1], Bashir Mahamud[1], R Shrestha[1], A Awan[1], E Lau[1], B Bhatt[1], Dalya Sadulah[1], A Rameshkumar[1], M Dram[1], M Sun[1], B Hossain[1] & Gideon Mlawa[1]
[1]Barking, Havering, and Redbridge University Hospitals NHS Trust, Romford, United Kingdom, London, United Kingdom

Introduction
Hydroxychloroquine (HCQ) is an antimalarial and immunomodulatory drug commonly used in the treatment of systemic lupus erythematosus (SLE) and other autoimmune conditions. It is generally well-tolerated, with known adverse effects including retinal toxicity, cardiomyopathy, and gastrointestinal symptoms. However, hypoglycemia is a rare but documented side effect of HCQ, potentially due to increased insulin sensitivity and enhanced glucose uptake by peripheral tissues. This case report presents a 28-year-old female with multisystem lupus who developed recurrent hypoglycemic episodes despite no prior history of diabetes. The recognition of HCQ-induced hypoglycemia, along with appropriate medication adjustments, highlights the importance of clinician awareness regarding this uncommon but significant adverse effect.
Case
A 28-year-old female with multisystem lupus, including cardiac, renal, respiratory, and skin involvement, was admitted with right iliac fossa pain and a background of lupus serositis. She was started on HCQ **200mg twice daily on 20/05/23**, reduced to **200mg once daily on 30/05/23**, and later increased back to **200mg twice daily** before being stopped on **06/06/23**. The patient exhibited repeated low capillary blood glucose (CBG) readings, particularly from 27/05/23 to 06/06/23, with several episodes below 2.5mmol/L. Severe hypoglycemic episodes: 01/06/23: CBG 1.7–1.8mmol/l04/06/23: CBG 1.3–2.8mmol/lDuring admission, she experienced recurrent hypoglycemic episodes, with capillary blood glucose (CBG) readings as low as **0.7 mmol/lon 06/06/23**, despite

remaining alert with cold hands. Arterial blood gas (ABG) glucose was normal at **8.9 mmol/L**, suggesting falsely low CBG readings due to poor perfusion.
Management and Outcome
The endocrinology team reviewed her on **31/05/23**, and it was suspected that HCQ contributed to the hypoglycemia. Despite ongoing corticosteroid treatment, her blood glucose remained intermittently low. After discontinuing HCQ on **06/06/23**, her glucose levels stabilized without further episodes of hypoglycemia.
Discussion
Unexplained hypoglycemia in non-diabetic patients on HCQ should prompt consideration of drug-induced causes. Falsely low CBG readings can occur due to Raynaud's phenomenon or poor peripheral perfusion, necessitating confirmation with serum glucose or ABG glucose levels. Discontinuation of HCQ led to resolution of hypoglycemia, highlighting the importance of early recognition and appropriate medication adjustment. Multidisciplinary involvement (rheumatology, endocrinology, renal, and cardiology teams) is crucial in complex cases with multisystem involvement.
Conclusion
This case highlights hydroxychloroquine-induced hypoglycemia as a rare but clinically relevant adverse effect. Clinicians should be aware of this possibility, particularly in patients without diabetes who develop unexplained hypoglycemia. Regular blood glucose monitoring and multidisciplinary management are essential for early recognition and intervention.

Adjustment of medication in patients with nasogastric tube or gastrostomy

Jose Antonio Ariza Jimenez[1], Claudia Perez Ahijon[2], Diego Garcia Cortes[2], Silvia Patricia Alonso Gallardo[1], Ruth Holgado Ramirez[1] & Vicente Faus Felipe[2]
[1]Hospital Universitario Costa del Sol, Endocrinology and Nutrition, Marbella (Málaga), Spain; [2]Hospital Universitario Costa del Sol, Pharmacy, Marbella (Málaga), Spain

Introduction
The administration of drugs via a nasogastric tube or gastrostomy is a common practice in patients who are unable to take oral medications due to swallowing difficulties, neurological disorders, or other medical conditions. However, this route of administration presents several challenges, including the risk of tube obstruction, reduced drug efficacy, and potential drug-nutrient interactions. Some medications are not designed to be crushed or dissolved, which may alter their pharmacokinetics and pharmacodynamics, leading to suboptimal therapeutic effects or increased risk of adverse reactions. To address these issues, our hospital has implemented a structured, multidisciplinary evaluation process involving the Endocrinology/Nutrition and Pharmacy Departments. This collaboration aims to ensure that all medications administered via nasogastric tube or gastrostomy are appropriate, safe, and effective for each patient.
Objectives
This study evaluates the impact of a multidisciplinary team on medication reconciliation and adjustments for patients requiring drug administration via nasogastric tube or gastrostomy. It aims to identify common pharmaceutical interventions, determine frequently modified drug classes, and highlight the significance of interprofessional collaboration in patient care.
Material and Methods
We conducted a descriptive observational study from August 1, 2024, to December 15, 2024, documenting all interventions performed by the Endocrinology/Nutrition and Pharmacy team. The study included all hospitalized patients with a nasogastric tube or gastrostomy at discharge, as well as those attending nutrition consultations. The Pharmacy Department reviewed patient treatment plans with the patient or their caregivers, based on electronic prescription records. Necessary modifications were proposed to the Endocrinology team to ensure safe and effective drug administration. All changes were systematically recorded and analyzed.
Results
A total of 50 patients (52% men, 48% women) were included, with a mean age of 74 years. Medication modifications were required in 76% of cases, with a total of 66 changes recorded. The most frequent interventions included:.
- Modification of pharmaceutical form (31.3%).
- Adjustment of administration method (31.3%).
- Substitution with a therapeutic equivalent (16.4%).
- Discontinuation due to lack of evidence or incompatibility (13.4%).
- Prescribing separately (7.5%).

The most adjusted drug classes were proton pump inhibitors (12 patients), acetylsalicylic acid (9 patients), and levothyroxine (6 patients).
Conclusions
- Medication adjustments were necessary for 76% of patients with nasogastric tube or gastrostomy.
- Proton pump inhibitors and acetylsalicylic acid were the most frequently modified drug classes.
- This study underscores the importance of multidisciplinary collaboration in medication reconciliation to enhance patient safety and treatment efficacy.

Therapeutic adherence to antihypertensive treatment in type 2 diabetes: barriers to achieving blood pressure targets

Yesmine Elloumi[1], Ekram Hajji[1], Bilel Ben Amor[1], Zeineb Rekaya[1], Hanene Sayadi[1] & Ines Khochtali[1]
[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Background
Blood pressure control is crucial in managing patients with type 2 diabetes mellitus (T2DM) to prevent cardiovascular complications. However, many patients face challenges in reaching the recommended blood pressure targets. Therapeutic adherence to antihypertensive treatments plays a key role in the effectiveness of treatment, yet it is often hindered by various barriers. This study explores the challenges faced by T2DM patients regarding adherence to antihypertensive treatments and its impact on achieving blood pressure targets.
Methods
This descriptive cross-sectional study was conducted on 80 patients with T2DM who had been under follow-up for more than six months at the Endocrinology department of Fattouma Bourguiba University Hospital in Monastir, Tunisia.
Results
Among the 80 patients, 65% were female, with a mean age of 57.9 years. Notably, 57.5% were being treated for hypertension. The mean systolic blood pressure was 140 mmHg [120-160], while the mean diastolic blood pressure was 90 mmHg [80-100]. In terms of antihypertensive therapy, 20% were on monotherapy, 17.5% on combination therapy, and 11.3% on triple therapy. However, 26.3% of patients did not achieve the recommended blood pressure targets. Therapeutic adherence was found to be influenced by several factors, which in turn impacted blood pressure control. These factors included therapeutic inertia (16.3%), which was the most prevalent issue, followed by patient negligence (2.5%) and cost-related barriers (5%). In addition, gastrointestinal intolerance (6.3%), forgetfulness (3.8%), and unavailability of the treatment (11.3%) were also identified as significant contributors.
Conclusion
Therapeutic adherence to antihypertensive treatment in T2DM patients is influenced by a variety of factors, many of which hinder the achievement of optimal blood pressure targets. Addressing these barriers is crucial for improving blood pressure control and reducing the risk of cardiovascular complications in this population.

Homozygous familial hypercholesterolemia: a rare case in a multiple pregnancy

Nassim Ben Hadj Slama[1], Hamza Elfekih[1], Amira Yanes[1], Wiem Saafi[1], Dorra Hmida[2], Soumaya Mougou[2], Sawssen Mrad[3], Ghada Saad[1] & Yosra Hasni[1]
[1]Farhat Hached University Hospital, Endocrinology, Sousse, Tunisia; [2]Farhat Hached University Hospital, Genetics, Sousse, Tunisia; [3]Farhat Hached University Hospital, Biochemistry, Sousse, Tunisia

Introduction
Homozygous familial hypercholesterolemia is a rare condition, with an estimated prevalence of 1 in 1 million individuals. Cases in multiple pregnancies have been scarcely reported in the literature.
Case Report
We report the case of a 15-year-old boy with no prior history of hypercholesterolemia, hospitalized for acute coronary syndrome. He was born to parents in a second-degree consanguineous marriage. He has three 12-year-old sisters from a trizygotic trichorionic multiple pregnancy. On examination, he presented with tendinous xanthomas, planar xanthomas, xanthelasma, and gerontoxon. Laboratory tests revealed severe hypercholesterolemia, with an LDL cholesterol level of 23 mmol/L. The Dutch Lipid Clinic Network criteria confirmed a diagnosis of

definite familial hypercholesterolemia. Family screening identified hypercholesterolemia in several relatives, including one sister with a clinical and biological profile similar to the patient's. The other two sisters from the triplet pregnancy also had hypercholesterolemia, though at less severe levels. Genetic analysis within the family revealed a severe LDL receptor gene mutation in the homozygous form in the patient and his similarly affected sister. The same mutation was found in a heterozygous form in the parents and the other two sisters. LDL apheresis was recommended for the homozygous patient and his affected sister, while the rest of the family was started on statins and ezetimibe.

Discussion

Homozygous familial hypercholesterolemia leads to early-onset atherosclerosis and premature death, often in the second decade of life. The LDL receptor gene mutation identified in our patients is classified as severe, with homozygous individuals retaining less than 2% of functional LDL receptors. While novel therapies may offer promising results, their high cost limits accessibility in our country. In our setting, LDL apheresis remains the only feasible and effective treatment. This case is exceptional due to the presence of familial hypercholesterolemia in triplet sisters from a multiple pregnancy. The different genotypes observed among the sisters are explained by the trizygotic trichorionic nature of the pregnancy, with one sister being homozygous and the other two heterozygous.

JOINT3743

A rare case of idiopathic ketotic hypoglycemia in a child from kazakhstan

Karlygash Medegali[1], Marzhan Rakhimzhanova[1], Dariya Gosman[1] & Ayazhan Abikenova[1]
[1]CF UMC, Astana, Kazakhstan

Introduction

Idiopathic ketotic hypoglycemia (IKH) is the most common cause of recurrent fasting hypoglycemia in young children. It is characterized by fasting-induced hypoglycemia with ketosis in the absence of identifiable endocrine or metabolic disorders. While IKH is often considered benign, it requires careful differentiation from other hypoglycemic conditions such as hyperinsulinism, adrenal insufficiency, and glycogen storage diseases. This case highlights a 4-year-old boy from Kazakhstan, focusing on diagnostic challenges, management, and the role of genetic testing.

Case presentation

We present the case of a 4-year-old boy admitted with recurrent early morning episodes of hypoglycemia (2.0–2.6 mmol/l)associated with lethargy and altered consciousness. These episodes had been occurring since the age of 2 and were unrelated to infections or prolonged fasting. Upon clinical evaluation, his growth parameters were normal (height 109 cm, weight 18.5 kg, BMI 15.15 kg/m^2, SDS -0.36). Laboratory findings during hypoglycemia revealed ketosis, elevated lactate (3.89 mmol/L), and low insulin (0.20 μIU/ml) and C-peptide (0.27 ng/ml) levels. Endocrinological workup ruled out hyperinsulinism, adrenal insufficiency, and growth hormone deficiency. Genetic testing (3B-EXOME, Proband) revealed no pathogenic variants, confirming the diagnosis of idiopathic ketotic hypoglycemia. Management included frequent meals, uncooked cornstarch supplementation, and education on emergency hypoglycemia management using oral glucose and glucagon.

Conclusion

IKH is a diagnosis of exclusion, requiring thorough evaluations to rule out metabolic and endocrine disorders. This case demonstrates the role of genetic testing in confirming the diagnosis and the importance of tailored dietary strategies and family education in preventing severe hypoglycemia. A multidisciplinary approach is essential for effective management of this rare condition. Future research should focus on identifying potential genetic or metabolic biomarkers that could aid in earlier and more precise diagnosis. Additionally, investigating novel dietary or pharmacological interventions may help improve long-term management and prevent severe hypoglycemic episodes in affected children.

Relationship renin-angiotensin ratio with hypertension and disease duration in patients with type 2 diabetes mellitus

Shohista Karimjonova[1], Matluba Rahmonberdieva[1], Shakhnoza Akhmedova[1], Anna Alieva[2], Zokir Takhirov[3], Maftuna Takhirova[3] & Zulaykho Shamansurova[3,4]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Republican Specialised Scientific Practical Medical Centre of Endocrinology, Tashkent, Uzbekistan; [3]Central Asian University, Endocrinology, School of Medicine, Tashkent, Uzbekistan; [4]Institute of Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan

Introduction

In patients with type 2 diabetes mellitus, an increase in arterial blood pressure usually contributes to the development of complications. In this paper, we will examine the effects of hyperglycemia and the renin-aldosterone system on renal dysfunction, as well as the impact of arterial blood pressure correction on quality of life. Aim: To study the relationship between renin and aldosterone with the course and complications of the disease in patients with type 2 diabetes mellitus.

Materials and Methods

Patients diagnosed with type 2 diabetes mellitus at the Republican Specialised Scientific Practical Medical Center of Endocrinology during 2022-2024 were included in the study. Among them, 51.25% were women, and 48.75% were men. The average age of male patients was 48.6 ± 2.54, and the average age of female patients was 53.41 ± 1.65. Normal arterial blood pressure was detected in 23 (28.75%) of them (NBP), while high arterial blood pressure was detected in 57 (71.25%) patients (HTN).

Results

The duration of the disease was found to be 5.5 ± 0.54 in patients with normal arterial blood pressure and 9.8 ± 0.5 ($P = 2.818$) in patients with high arterial blood pressure. HbA1C was found to be 10.89 ± 0.40 in NBP and 12 ± 0.4 ($P = 2$) in HTN. VLDL cholesterol was 1.08 ± 0.1 in NBP and 1.2 ± 0.06 ($P = 3.226$) in HTN. HDL cholesterol was 2.2 ± 0.23 in NBP and 1.4 ± 0.12 ($P = 3.314$) in HTN. Renin was found to be 0.54 ± 0.11 in NBP and 0.54 ± 0.1 ($P = 12.635$) in HTN. Aldosterone was 0.92 ± 0.06 in NBP and 0.9 ± 0.04 ($P = 2.095$) in HTN. When patients compared by disease duration Renin aldosterone ratio were decreased probably due to Diabetic Nephropathy.

Conclusions

In patients with type 2 diabetes mellitus, renin and angiotensin were found to be high relative to arterial blood pressure. It was determined that as the duration of the disease increased, these indicators decreased, which was related to the functional state of the kidneys.

Interim analysis of equol producer prevalence in the isoflavone study

Olivia Trummer[1], Ines Ivic[2], Veronika Tandl[1], Valentin Borzan[1], Natascha Schweighofer[1] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria; [2]FH Joanneum University of Applied Sciences, Graz, Austria

Background

Polycystic ovary syndrome (PCOS) is a common endocrine condition of heterogeneous origin, characterized by hyperandrogenism, oligo-/amenorrhoea, and/or polycystic ovarian morphology. PCOS phenotypes are associated with several comorbidities including depression, obesity and insulin resistance. Isoflavones are plant-derived hormones (phytoestrogens) with similar chemical structure and properties like estrogens. Soy products, among other nutrients, contain clinically relevant concentrations of isoflavones such as genistein and daidzein. The ability to derive health benefits from a soy-based nutrition is thought to depend on the production of the isoflavone metabolite equol, based on specific human gut bacteria. Equol has been shown to bind to estrogen-receptors alpha and beta and to have anti-androgenic, anti-cancer and anti-inflammatory effects and is therefore of particular interest for women with PCOS. However, in Western countries, only 25-30% of the population are so-called "equol-producers" and have the appropriate bacteria to convert daidzein to equol. The prevalence in women with PCOS was reported to be even lower. The present interim analysis of the Isoflavone Study aimed to assess potential differences in the prevalence of equol-producers among women with PCOS, healthy women and healthy men.

Methods

After a one-day consumption of 2x200 ml soy drink, equol and daidzein concentrations in the morning urine of the following day were measured by gas chromatography and mass spectrometry (GC-MS) in the women enrolled with PCOS ($n = 33$), in control women ($n = 13$) and men ($n = 45$). A cut-off value for the log10-transformed urinary equol:daidzein ratio of -1.75 was used to define equol production.

Results
Prevalence of equol-producers was 38.5% in the PCOS-group, 40.0% in healthy women and 27.9% in men. The frequency of equol producers did not differ across the groups, nor between women with PCOS and the control group, nor between women with PCOS and men. Equol-daidzein ratio was -1.9 $\pm$ 0.8 in women with PCOS, -1.8 $\pm$ 0.8 in the control group and -2.0 $\pm$ 0.8 in the group of men.
Conclusion
Equol producer prevalence in Western countries is around 30-40%. In our interim analysis, we found no significant differences among women with PCOS, healthy women, and healthy men. Similarly, the equol-daidzein ratio did not show meaningful variation between the groups. However, due to the limited sample size, these results should be interpreted with caution. A final analysis after full recruitment is necessary to confirm these first findings and to provide more robust conclusions.

Microbiota and obesity: current state and outlook
Salma Mohsen[1], Khaoula Sallem[1], Arwa Guediche[1], Syrine Daada[2] & Dorra Ben Salem[2]
[1]CHU Fattouma Bourguiba, Gastro-enterology, Monastir, Tunisia; [2]CHU Fattouma Bourguiba, Endocrinology, Monastir, Tunisia

Introduction
The obesity, a multifactorial disease, is arousing growing interest in the role of the gut microbiota. The aim of this study is to explore the complex links between the composition of the microbiota and the development of obesity. Through a literature review, we will examine the various proposed hypotheses, the physiological mechanisms involved, and the therapeutic prospects offered by modulation of the microbiota.
Methods
To carry out this work, we carried out a quite wide-ranging bibliographical search in the following databases: PubMed, Science Direct and Google Scholar to identify the most relevant articles. After excluding duplicates, we retained 26 appropriate articles.
Results
Obesity is associated with changes in the composition of the gut microbiota, essentially a higher Bacteroidetes/Firmicutes ratio, which may influence energy storage, inflammation and insulin resistance. High-fat diets can alter microbiota, leading to increased intestinal permability which contribute to low-grade inflammation and obesity. Antibiotic treatment of mice reduced metabolic endotoxemia and improved glucose tolerance, body weight and markers of inflammation. The intestinal microbiota affects host metabolism through various mechanisms, including colonic fermentation of non-digestible fibres and modulation of the endocannabinoid system. Strategies aimed at the composition of microbiota, such as prebiotics and probiotics, may offer potential interventions for the management of obesity. In addition, factors such as mode of birth, breastfeeding can influence the early development of the infantil microbiota, which may have an impact on future metabolic health.
Conclusion
These results are encouraging, but many challenges remain. The complexity of gut microbiota, the uniqueness of responses and the eventual interactions with other factors make it particularly challenging to put in place a large-scale personalised therapeutic strategies.

Eating habits and dietetic management of obesity in children and adolescent
Dhoha Ben Salah[1], Ameni Ben Abdallah[1], Kouloud Boujelben[1], Nada Hassairi[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Department of Endocrinology Hedi Chaker Hospital, Sfax, Tunisia

Introduction
dietary management is the most important step in the childhood obesity care. The aim of this study is to analyze dietary habits in a pediatric population who are obese and to evaluate the effectiveness and adherence of patients to the prescribed diet at 6 months of follow-up.
Methods
We carried out a cross-sectional study, which concerns obese children who are referred to the endocrinology department in Hédi Chaker hospital in Sfax. Then we have assessed the weight status after six months under regime. A sample of 84 children who are overweight and obese were recruited into the study. All the children included in our study were put under diet adapted according to the age during 6 months.
Results
Eighty-four children, forty-four boys and forty girls. The average age was eleven point eighty-three years. The average BMI was thirty-one point fifty-five kg/m^2 (twenty-one to forty-seven), the average BMI Z score was seven point nine SD (two point seven to sixteen). The daily calorie intake was two thousand four hundred eighty-four kcal per day. This weight loss was not statistically significant. After six months of follow-up: good adherence was observed in twenty-three percent. The average BMI was twenty-nine point six kg/m^2, the average BMI Z score was seven point five SD. Half of our patients have decreased their BMI Z-score. The prescribed diet was more effective in boys than in girls, in patients without a family history of obesity, in patients who were physically active, in patients who are overweight without obesity, and in those who were more adherent. But this efficiency remains statistically insignificant.
Conclusion
This study showed that there is a positive impact of dietary management on weight reduction in children. Other studies have shown the value of dietetic management on childhood obesity care particularly through multidisciplinary interventions.

Floating-harbor syndrome in a 39-year-old patient: description of a rare obesity clinical case
Raisat Guseinova[1], Anastasia Averkina[1], Manushak Rafaelyan[1], Rita Khusainova[1], Ramil Salakhov[1], Daria Kopytina[1], Ildar Minniakhmetov[1] & Olga Vasyukova[1]
[1]Endocrinology Research Center, Moscow, Russian Federation

Floating-Harbor syndrome (FHS) is an extremely rare autosomal dominant genetic disorder with specific features, including facial dysmorphia, skeletal abnormalities (delayed bone age), and intellectual, speech, and systemic impairments. It is caused by mutations in the SNF-2-related CREBBP activator protein (SRCAP) gene. As of 2021, over 100 cases of FHS have been reported globally, with the first case described in 1973. Hyperphagia is not typical and GH treatment has limited effects on short stature in FHS. Clinical case: Patient E., 39 years old, presented with complaints of obesity that is difficult to manage and increased appetite. Her medical history indicates that she was born following a normal pregnancy and had normal weight and growth parameters at birth. Neonatal hypotonia was absent, and the sucking reflex was normal. However, from an early age, she exhibited delays of growth, intellectual and speech development, learning difficulties, bilateral sensorineural hearing loss, hyperphagia, and progressive weight gain. She received no GH treatment. Notably, she showed persistent obsessions related to food-seeking behavior. At the age of 25, Prader-Willi syndrome was suspected, but no molecular genetic testing was performed. She also underwent surgery for a paraovarian cyst and cholelithiasis. At the age of 37 she suffered an acute ischemic stroke. Upon examination, notable phenotypic features were observed: acromicria, microcephaly, short stature (height 150 cm, weight 92 kg), broad deep-set eyes, a large bulbous nose, short neck, clinodactyly V and a cleft upper lip. No respiratory disturbances, sleep apnea, IGF1 or thyroid test abnormalities were revealed. Impaired glucose tolerance, mild liver enzymes elevation due to NAFLD and hyperuricemia were identified. Given the absence of convincing data characteristic of Prader-Willi syndrome, along with the unclear clinical picture, patient history, and her phenotypic characteristics, FHS was suspected. This diagnosis was confirmed by genetics - whole-exome sequencing, which revealed a heterozygous variant in the SRCAP gene (c.7330C>T). Following treatment with GLP-1 agonists, the patient experienced a reduction in body mass by 13% from baseline, with control of glucose metabolism and other metabolic disturbances and hyperphagia reduction.
Conclusion
A diagnosis of FHS is suspected when typical clinical findings are present and can be confirmed through SRCAP gene sequencing. We report a late diagnosis case masked by a hyperphagia leading to morbid obesity, although it is treatable with GLP-1-analoges. It is important to remember that obesity is not only a symptom but also a potential indicator of complex genetic disorders.

Real-world effect of tirzepatide: a prospective observational study

Lidia Urbon Lopez de Linares[1]
[1]Hospital Universitario de Burgos, Burgos, Spain

Introduction
Tirzepatide is a novel dual GLP-1 and GIP receptor agonist that has demonstrated promising results in managing obesity and type 2 diabetes. By targeting both insulin secretion and glucagon suppression, tirzepatide helps improve metabolic control and reduce body weight, making it an exciting therapeutic option for patients with high body mass index (BMI) and related comorbidities.
Objective
To assess the real-world effects of tirzepatide (5 mg dose) on weight, LDL cholesterol, and basal glucose levels in patients with a mean BMI of 45.7.
Study Design
Prospective observational study.
- **Participants**: 20 subjects (4 males).
- **Mean Age**: 49.7 years.
- **Mean BMI**: 45.7.

Intervention.
- Tirzepatide 5 mg administered for 3 months.

Results
- **Mean Weight Reduction**: 9.9 kg.
- **Mean LDL Reduction**: 23.3 mg/dl.
- **Mean Basal Glucose Reduction**: 10.3 mg/dl.

Conclusion
In this real-world observational study, tirzepatide demonstrated significant reductions in weight, LDL cholesterol, and basal glucose levels after 3 months of treatment.

Nutritional profile of obese adolescents

Mouna Elleuch[1], Yesmine Elloumi[1], Hanen Krichen[2], Mouna Mnif[1], Dhoha Ben Salah[2] & Nabila Mejdoub Rekik[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Sfax, Tunisia

Background
Adolescent obesity has become a critical issue globally, with diet playing a pivotal role in its development. Despite the increasing prevalence of obesity in this age group, the dietary habits contributing to this condition remain underexplored. Understanding these dietary habits is crucial to addressing the root causes of obesity in adolescents. This study aims to highlight the dietary profile of adolescents with obesity.
Methods
A retrospective study involved obese adolescents, followed at the Endocrinology Department of Sfax, Tunisia, for obesity management. A dietary survey was conducted during a nutritional counseling session. The survey data were analyzed using the "BILNUT" software to obtain nutritional information.
Results
The study population consisted of 58 adolescents with a sex ratio of 0.49. The mean age of the patients was 15.4 $\pm$ 2 years. The total energy intake was 2475.9 kcal/day $\pm$ 686, with carbohydrate intake averaging 54.3% $\pm$ 5.2, showing no significant gender difference ($P = 0.091$). Simple sugar intake was 3.7% $\pm$ 2.6. Among patients, 44.8% had adequate carbohydrate intake, 12.1% had insufficient intake, and 43.1% had excessive intake. Lipid intake was 34.8% $\pm$ 4.8, with no significant difference between genders ($P = 0.070$), except for polyunsaturated fatty acids ($P = 0.018$). Saturated fatty acids accounted for 7.8% $\pm$ 1.5, while monounsaturated fats made up 16.4% $\pm$ 4.5. Regarding fat intake, 51.7% had normal levels, 8.6% had insufficient intake, and 39.7% had excessive intake. Protein intake was 61.5% $\pm$ 20.8, but only 22.4% of patients had a normal protein intake, while 77.6% followed a protein-poor diet. Protein intake was not significantly associated with gender ($P = 0.771$), nor was cholesterol intake ($P = 0.159$). Cholesterol intake was normal in 10.3%, insufficient in 55.2%, and excessive in 34.5%. Calcium intake (<800 mg/day) was insufficient in 94.8% of cases, while iron intake was deficient in 94.7% of boys and in all girls. The average fiber intake was 15.9 $\pm$ 6.3 g/day. Boys had significantly higher fiber intake compared to girls ($P = 0.009$), and a fiber deficiency (<20 g/day) was found in 77.6% of cases. Finally, vitamin C intake averaged 60.3 mg/day $\pm$ 36.4, with no significant difference between genders ($P = 0.700$).
Conclusion
Analyzing the dietary profile of adolescents with obesity is essential for developing effective strategies to combat this growing public health challenge.

Clinical profile of obese adolescents

Mouna Elleuch[1], Yesmine Elloumi[1], Hanen Krichen[1], Dhoha Ben Salah[1] & Nabila Mejdoub Rekik[1]
[1]Hedi Chaker University Hospital, Sfax, Tunisia

Background
Obesity among adolescents has become a growing public health concern worldwide. This condition not only affects physical health but also significantly impacts emotional well-being and social development. Adolescents with obesity face numerous challenges, including the risk of comorbidities that persist into adulthood. Despite the widespread recognition of obesity as a major health issue, there is limited understanding of its unique clinical profile in this age group. Therefore, it is crucial to examine the clinical features of obesity in adolescents.
Methods
This was a retrospective and analytical study involving obese adolescents, followed at the Endocrinology Department of Sfax, Tunisia, for obesity management between 2019 and 2023. Obesity was defined based on the reference charts from the National Nutrition and Health Program: Grade 1 obesity: body mass index (BMI) between the curve corresponding to a BMI of 25 kg/m^2 at 18 years and the curve corresponding to a BMI of 30 kg/m^2 at 18 years. Grade 2 obesity: BMI above the curve corresponding to a BMI of 30 kg/m^2 at 18 years. A professional body composition analyzer was used to measure weight, fat mass, lean mass, and body water content.
Results
The study population consisted of 58 adolescents with a sex ratio of 0.49. The mean age of the patients was 15.4 $\pm$ 2 years. The average age of obesity onset was 8.4 $\pm$ 4 years. The most common triggering factors for obesity were dietary habit changes (44.8%) and puberty (34.5%). A progressive worsening of obesity was observed in 82.2% of cases, while 17.2% had a rapid progression. The adolescents had a mean BMI of 34.2 $\pm$ 6.2 kg/m^2, with no significant difference between genders ($P = 0.169$). Obesity distribution showed that 22.4% of adolescents had grade 1 obesity, while 77.6% had grade 2 obesity. Obesity appeared to be more severe among girls ($P = 0.243$). Waist circumference also showed no significant difference between genders ($P = 0.832$). Fat mass was significantly higher in girls ($P = 0.021$), whereas lean mass and water content were higher in boys ($P = 0.013$ and $P = 0.012$, respectively). The impact of obesity was gonadal in 15.5%, metabolic in 13.8%, respiratory in 8.6%, psychiatric in 6.9%, osteo-articular in 3.4%, and cardiovascular in 3.4%.
Conclusion
Understanding the clinical profile of obesity in adolescents is essential for developing targeted interventions to address this growing public health issue.

Biological findings of obese adolescents

Yesmine Elloumi[1], Mouna Elleuch[1], Hanen Krichen[2], Dhoha Ben Salah[1] & Nabila Mejdoub Rekik[1]
[1]Hedi Chaker University Hospital, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Adolescent obesity has become a rising global public health issue, affecting not only physical health but also influencing emotional well-being and social development. While obesity is widely recognized as a major health concern, the biological profile of this condition in adolescents remain underexplored. Therefore, it is essential to investigate the biological aspects of obesity in this age group to enhance understanding and improve prevention and management strategies.
Methods
A retrospective analytical study included obese adolescents treated for obesity at the Endocrinology Department of Sfax, Tunisia, between 2019 and 2023. Obesity was defined according to the reference charts of the National Nutrition and Health Program.

Results
The study population consisted of 58 adolescents with a sex ratio of 0.49. The mean age of the patients was 15.4 ± 2 years. Prediabetes was observed in 5 cases (8.6%), while diabetes was found in only 1 case (1.7%). The mean glycated hemoglobin and glucose levels were 5.3% ± 0.5 and 4.6 mmol/l± 0.8, respectively. Hypertriglyceridemia, with a mean of 1.5 mmol/l± 3, was found in 6 cases (10.3%), while hypercholesterolemia occurred in 4 cases (6.9%) with a mean of 4 mmol/l± 0.7. HypoHDLemia was noted in 39 cases (67.2%) with an average of 1.1 mmol/l± 0.3. HyperLDLemia was not observed in any cases, with the mean level being 2.5 mmol/l± 0.6. The mean uric acid level was 311.7 µmol/l± 79.5. We identified a single case of negative Dexamethasone suppression test (1.7%) and 6 cases (10.3%) with elevated TSH levels. The average calcium level was 2.35 mmol/l± 0.12. Sodium and potassium intake averaged 138.8 mmol/l± 2.4 and 4 mmol/l± 0.4, respectively. The mean creatinine level was 49.5 µmol/l± 8.3.
Conclusion
Gaining insight into the biological profile of obesity in adolescents is crucial for designing targeted interventions to combat this escalating public health concern.

Metabolic risk factors in overweight women with polycystic ovary syndrome: results of a tunisian study
Sana Khamassi[1], Kamilia Ounaissa[1], Taieb Ach[2], Ramla Mizouri[3], faten mahjoub[3], Haifa Abdesselem[1], Yasmine Fakhfakh[1], Emna Bornaz[1], Asma Ben Brahim[1], Rym Yahyaoui[1], Jamoussi Henda[3] & Chiraz Amrouche[1]
[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]Farhat Hached Hospital, Department of Endocrinology and Diabetology, Sousse, Tunisia; [3]National Institute of Nutrition and Food Technology, UR17SP01-Clinical Biology Laboratory, Tunis, Tunisia

Background
Given the growing evidence linking Polycystic Ovary Syndrome (PCOS) with metabolic risk factors, understanding the specific metabolic profiles in overweight women with PCOS is essential for developing effective management strategies [1]. Therefore, the aim of our study was to assess metabolic risk factors in a group of overweight women with PCOS.
Methods
This was a descriptive, cross-sectional, and retrospective case-control study involving 61 overweight women within the reproductive age range, divided into two groups: 31 women with PCOS and 30 women without PCOS. The groups were matched for age and body mass index (BMI). Clinical and biological data were extracted from the patients' medical records.
Results
The mean age at diagnosis of PCOS was 23.4±7.3 years, with extremes ranging from 14 to 39 years. Hirsutism, alopecia, and acne were observed in 78%, 60%, and 45% of PCOS patients, respectively. Biological hyperandrogenism was found in 66% of the patients with PCOS. Regarding menstrual cycle disorders, amenorrhea, oligomenorrhea, and infertility were observed in 54%, 47%, and 19% of cases, respectively. The majority of patients with PCOS had phenotype A (81%), while 19% had phenotype C. Among the patients with PCOS, 44% were treated with dydrogesterone and 28% were on metformin. Our study revealed a significantly higher frequency of type 2 diabetes in patients with PCOS compared to the control group (97% vs 18%; $P = 0.0001$). However, fasting blood glucose, HbA1c, and the HOMA index were comparable between the two groups ($P = 0.06$, $P = 0.13$, and $P = 0.71$, respectively). Women with PCOS had a significantly higher frequency of hypertension (90% vs 19%; $P = 0.0001$), metabolic syndrome (97% vs 54%; $P = 0.0001$) and dyslipidemia (90% vs 54%; $P = 0.002$) compared to the control group. The lipid profile parameters were similar in the two groups.
Conclusion
Our findings emphasize the need for targeted metabolic risk management in overweight women with PCOS. Early identification and intervention are crucial to reducing the long-term health risks associated with this condition.

Hemoglobin levels as a potential predictor of sarcopenia in obese patients
Sana Khamassi[1], Fatma Boukhayatia[1], Haifa Abdesselem[1], Emna Bornaz[1], Kamilia Ounaissa[1], Nesrine Dhieb[2], Rahma Mahjoub[3], Houda Bouhajja[2], Amel Gammoudi[4], Awatef Kacem[4], Emna Talbi[4], Jamoussi Henda[2] & Chiraz Amrouche[1]
[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology, Obesity Reserach Unit, Tunis, Tunisia; [3]National Institute of Nutrition and Food Technology, Clinical Biology Laboratory, Tunis, Tunisia; [4]National Institute of Nutrition and Food Technology, UR17SP01-Clinical Biology Laboratory, Tunis, Tunisia

Background
As a biomarker for anemia and nutritional status, hemoglobin (Hb) may also influence the progression of sarcopenia. Although research on this topic remains limited, insufficient Hb levels can impair oxygen delivery to skeletal muscles, potentially affecting muscle strength and function. This study aimed to evaluate the impact of Hb levels on sarcopenia in obese patients.
Methods
This is a cross-sectional study conducted on 100 obese patients. Body composition was assessed using SECA MBCA 515 bioimpedance. Sarcopenic obesity (SO) was defined in accordance with the EASO-ESPEN consensus statement [1].
Results
The mean age was 44.42±13.25 years with a male-to-female ratio of 0.11. The mean BMI was 40.07 ± 5.77 kg/m^2, with almost half of the group categorized as morbidly obese (48%). Abdominal obesity was found in the entire population with a mean waist circumference of 116.51 ± 16.62 cm. The mean hemoglobin levels were 15.14 ± 1.28 g/dl in male patients and 13.11 ± 1.30 g/dl in female patients. Anemia was present in 18% of the participants, and sarcopenia was diagnosed in 19% of the study population. Our study found that hemoglobin levels were positively correlated with skeletal muscle mass ($r = 0.38$; $P < 0.001$), appendicular muscle mass ($r = 0.37$; $P < 0.001$), and muscle strength ($r = 0.23$; $P = 0.019$). Patients with anemia had significantly lower skeletal muscle mass (24.34 ± 3.19 kg vs. 27.38 ± 7.06 kg; $P = 0.007$) and appendicular muscle mass (14.71 ± 1.93 kg vs. 16.47 ± 4.34 kg; $P = 0.015$). Anemia was more frequent in patients with sarcopenia (21.1% vs. 17.3%), though this difference was not statistically significant.
Conclusion
The results of our study suggest that hemoglobin levels may be an important factor in the development of sarcopenia in obese patients, highlighting the need for further research in larger cohorts.

JOINT1269
The impact of obesity on the clinical manifestations of early menopause in women
Ziyoda Umarkhodjaeva[1], Sitora Muminova[2] & Dildora Sadikova[1]
[1]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after Ya.Kh. Turakulova, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

Aim
To investigate the influence of different degrees of excess weight on the progression of menopause.
Materials and Methods
The study involved 278 women in the menopausal period, aged 40 to 46 years. The main group (MG) consisted of 218 women with varying degrees of overweight and obesity. The control group (CG) included 60 women with normal body weight and a waist circumference of 80 cm. The severity of climacteric syndrome was assessed using the Greene Climacteric Scale.
Results
The study found that among 218 women in the main group, 62 (28.4%) were classified as overweight (BMI 25.0–29.9 kg/m^2), while the rest had varying degrees of obesity (BMI 30.0–41.2 kg/m^2). Notably, 72.0% of overweight women reported gaining weight after the age of 36. The prevalence of comorbid

conditions was high among individuals with excess body weight, with arterial hypertension observed in 36% of the main group, ischemic heart disease in 22%, chronic venous insufficiency in 10%, and arrhythmias in 10%. Additionally, the occurrence of gynecological disorders correlated with BMI levels. Among overweight women, 58.4% had conditions such as uterine fibroids and adenomyosis, whereas these pathologies were found in only 13.8% of the control group.
Conclusion
In summary, increased central fat accumulation, reduced peripheral fat storage, and ectopic fat deposition contribute to cardiometabolic abnormalities, resulting in a higher prevalence of metabolic syndrome after menopause.

Management of obesity in children and young adolescents with type 2 diabetes

Foued Abdelaziz, Nihad Selim[1], Yahia Chebini[1] & Nadira Bouchair[1]
[1]Saint Therese Clinic, University Hospital of Annaba, Pediatrics, Annaba, Algeria

Introduction
Type 2 diabetes (T2D) is defined as hyperglycemia caused by insulin resistance, it was the prerogative of the adult subject but its frequency has increased significantly in recent decades in parallel with the increase in the rate of obesity. Management is either non-pharmacological involving diet management and physical activity (cases of diagnosis made in the context of screening or without metabolic decompensation), or pharmacological (in association with the above mentioned measures) with metformin and sometimes insulin therapy in the first weeks to compensate for insulinopenia (cases of metabolic decompensation).
Material and Methods
In our specialized pediatric endocrinology and diabetology consultation, we collected 34 children and young adolescents with T2D,.
Result
Among our patients, 26 of them have at least 2 years of evolution, 6 are on dietary measures only, 4 are on insulins with metformin and 16 are on metformin only. Patients who have remained overweight are on insulin with poor glycemic control, which further shows the role of obesity in insulin resistance.
Conclusions
The rate of T2D and obesity in children has increased in parallel, diet and weight management is a necessary condition for having a good glycemic balance.

JOINT1111

Association between overweight/obesity and iron deficiency among non-pregnant women of reproductive age in yerevan, armenia

Haykanush Hambardzumyan[1,2]
[1]Wigmore Womens and Childrens Hospital, endocrinology, Yerevan, Armenia; [2]Wigmore Women's & Children's Hospital, endocrinology, Yerevan, Armenia

Introduction
In 2022, 1 in 8 individuals globally lived with obesity. Approximately 2.5 billion adults aged 18 years and older were classified as overweight, including over 890 million adults with obesity. This equates to 43% of adults aged 18 years and over (43% of men and 44% of women). Obesity prevalence is notably higher in women. Iron deficiency anemia (IDA) is among the most common medical conditions worldwide, affecting approximately 29% of females of reproductive age, with iron deficiency accounting for 50% of cases. Iron is vital for hemoglobin synthesis, DNA synthesis mitochondrial energy production. Beyond anemia, iron deficiency (ID) can lead to significant health consequences, such as reduced physical and cognitive performance, particularly in non-pregnant females.
Methods
This cross-sectional study analyzed data from 343 non-pregnant women aged 15–45 years who visited the Wigmore Clinic endocrinology department between March 1, 2024, and December 30, 2024. The inclusion criteria included a body mass index (BMI) of 18–40 kg/m^2 and the absence of pregnancy, lactation, or specific chronic conditions (e.g., hematological, gastrointestinal, or gynecological diseases). Iron deficiency anemia (IDA) and iron deficiency (ID) were assessed through hemoglobin (Hb) and ferritin levels. Descriptive statistics were calculated for continuous and categorical variables. The participants' BMI ranged from 18 to 42 kg/m^2 (mean = 26.22, SD = 5.24). Hb levels ranged from 88 to 140 g/l(mean = 124.70, SD = 8.73), and ferritin levels ranged from 1 to 72 ng/ml (mean = 24.79, SD = 15.30). Most participants resided in urban areas (81.9%), were employed (64.4%), and had higher education levels (52.2%). Menstrual cycle abnormalities were reported by 8.5% of participants. BMI classifications included 38.2% normal weight, 38.2% overweight, and 23.6% obese. Ferritin categorization indicated 35.6% normal levels, 30.0% moderate ID, and 34.4% severe ID.
Results
The correlation between BMI and Hb was negligible ($r = -0.001$, $P = 0.987$), indicating no statistically significant relationship. However, a weak positive correlation was observed between BMI and ferritin levels ($r = 0.114$, $P = 0.035$) , suggesting a slight increase in ferritin levels with rising BMI. This relationship, though weak, was statistically significant.
Conclusions
The findings highlight a statistically significant but weak association between BMI and ferritin levels, whereas no relationship was observed between BMI and Hb levels. These results underscore the importance of monitoring iron status in women of reproductive age, particularly in those with elevated BMI, to mitigate potential health consequences.

Height loss with age in adults with prader willi syndrome may result in artifactual increases in BMI

Harry Hirsch[1], Harel Arzi[2,3], Fortu Benarroch[2,4,5] & Varda Gross-Tsur[2,4]
[1]Shaare Zedek Medical Center, Israel Multidisciplinary Prader Willi Clinic, Neuropediatric Unit, Jerusalem, Israel; [2]Shaare Zedek Medical Center, Israel Multidisciplinary Prader-Willi Syndrome Clinic, Neuropediatic Unit, Jerusalem, Israel; [3]Shaare Zedek Medical Center, Department of Orthopedics, Jerusalem, Israel; [4]The Hebrew University School of Medicine, Jerusalem, Israel; [5]Hadassah-Hebrew University Medical Center, Herman Dana Division of Child and Adolescent Psychiatry, Jerusalem, Israel

Modest decreases in height occur during normal aging, but usually have only a minimal effect on BMI (body mass index). Height loss may result from vertebral fractures, disc collapse, kyphosis, and/or scoliosis. Accurate determinations of BMI values are essential for prescribing diet and exercise regimens especially for adults with Prader-Willi syndrome (PWS). At the time of routine yearly visits to our national multidisciplinary PWS clinic, we measured standing heights in 28 PWS adults over a duration 11.3±3.4 (range 5.1 to 16.2) years. Most had no or only minimal height loss, but in four individuals measured heights decreased gradually over 7.9 to 16.1 years by 6.2, 6.6, 7.0, and 6.3 cm, respectively. Height loss for these four patients resulted in artifactually high BMI values compared to values based on the previously measured tallest heights. BMI values calculated by using the most recent heights compared to tallest height measurements were 41.4 vs 37.9, 31.9 vs 29.1, 31.0 vs 28.5, and 27.2 vs 24.8 kg/m^2, respectively. Adjustment of BMI for the tallest measured heights resulted in redefining obesity class from class III to class II in one individual, from obesity class I to "overweight" in two patients, and from overweight to normal in one man. Failure to recognize that an increase in BMI may be due to height loss rather than weight gain could lead to inappropriate recommendations for reduction in caloric intake. Even minor changes in diet restrictions can affect mood and behavior in individuals with PWS. Recognition of height loss as a contributing factor to BMI calculations is important for clinical studies evaluating effects of life-style changes and medical interventions for obesity.

The Relationship between morning blood pressure surge, serum antimüllerian hormone level and homa-ir score in patients with polycystic ovary syndrome

Dilan Damla Ozturk[1], Huseyin Ali Ozturk[2], Erdinc Gulumsek[2] & Hilmi Erdem Sumbul[2]
[1]Department of Internal Medicine, Yuregir State Hospital, Adana, Turkey, Adana, Türkiye; [2]Department of Internal Medicine, University of Health Sciences - Adana Health Practice and Research Center, Adana, Turkey, Adana, Türkiye

Aim
In our study, we aimed to investigate the relationship between antimüllerian hormone (AMH) and HOMA-IR score, which are known to be increased in patients with polycystic ovary syndrome (PCOS), and morning blood pressure surge (MBPS), and whether these measurements are a marker for early CVD risk in patients with PCOS.
Methods
40 patients aged between 18 and 65 years with hypertension (HT) and PCOS, 40 patients with HT but without PCOS, and 40 people representing the healthy control group were included in the study. All patients underwent ambulatory blood pressure measurement for 24 hours and MBPS was calculated.
Results
The study groups were divided into three groups as healthy control group (group 1), patient group with HT without PCOS (group 2) and patient group with HT and PCOS (group 3). MBPS was found to be statistically significantly higher in group 3. In linear regression analysis, AMH and HOMA-IR levels were found to be independently associated with MBPS. In patients with PCOS, AMH and HOMA-IR levels were significantly higher in the group with MBPS >25 mmHg.
Conclusions
Early diagnosis and treatment of PCOS and accompanying comorbidities can halt the progression of cardiac disorders and reduce cardiovascular mortality and morbidity. AMH level, HOMA-IR score and MBPS measurement can be used in early detection and prediction of CVD in PCOS patients.
Keywords
Antimüllerian hormone, HOMA-IR score, Insulin resistance, Polycystic ovary syndrome, Morning blood pressure surge.

A case with porphyria presenting with episodic hypertension and tachycardia mimicking pheochromocytoma

Gökçe Velioğlu Haşlak[1], Ayse Agbas[2], Esra Karabag Yilmaz[2], Tanyel Zubarioglu[3], Canan Koban Dogan[2], Nur Canpolat[2], Hande Turan[1], Olcay Evliyaoglu[1] & Elvan Bayramoglu[1]
[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Pediatric Endocrinology, Istanbul, Türkiye; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Pediatric Nephrology, Istanbul, Türkiye; [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Pediatric Metabolic Diseases and Nutrition, Istanbul, Türkiye

Introduction
The most common symptom of hypertension (HT) in childhood is headache, frequently accompanied by tachycardia. In infants and toddlers, it is predominantly caused by cardiac and renal pathologies, whereas essential HT is more common in adolescents. Among endocrinological disorders, pheochromocytoma is the leading cause of episodic HT. This case report highlights a rare condition that warrants consideration in the differential diagnosis of pheochromocytoma.
Case
A 17-year-old female presented with headache, palpitations and presyncope. Her systolic blood pressure was 170/100 mm Hg and pulse rate 135/minute. She responded to amlodipine but experienced recurrence during follow-up. Renal ultrasonography, renal doppler USG, plasma renin activity, angiotensin and aldosterone levels were normal. Investigating pheochromocytoma, urinary 3-Methoxytyramine levels were found to be elevated in two measurements, 174 μg/g and 533 μg/g. MIBG scintigraphy revealed subcentimetric lymph node involvement in the right paraaortic area. Clinical monitoring was deemed adequate, as the area was unsuitable for biopsy and not fully consistent with clinical findings. During follow-up, as hypertension and tachycardia persisted, the patient underwent PET-CT with gadolinium, showing no uptake. Thoracic and abdominal angiography were normal, but conventional angiography revealed contour irregularities and occlusions in distal branches of bilateral renal arteries, potentially indicating vasculitis. However, vasculitis was not considered due to lack of constitutional or cutaneous findings, no pulse and blood pressure discrepancy between extremities, and negative acute phase reactants and autoantibodies. Ramipril and metoprolol were respectively added to her treatment to control blood pressure. As hypertensive episodes continued and no benefit was observed, medications were gradually tapered. Urinary porphyria metabolite levels were analyzed, with porphobilinogen, delta-aminolevulinic acid and coproporphyrinogen III levels high in both attacks and attack-free periods. Intravenous dextrose infusion during a hypertensive episode reduced blood pressure and improved symptoms. A peripheral blood sample was obtained for genetic analysis to screen for porphyria-associated variations, with results pending.
Conclusion
While porphyria is characterized by cutaneous lesions, anemia, hepatic impairment, and neuropathies, some patients may present solely with tachycardia, HT, and presyncope episodes due to autonomic dysfunction. Although this clinical presentation resembles pheochromocytoma, paradoxical responses may be observed due to the precipitating effect of calcium channel blockers and angiotensin converting enzyme inhibitors on porphyria attacks. Intravenous administration of hemin or glucose during an acute episode provides significant clinical improvement. Porphyria should be considered in the differential diagnosis when encountering episodic hypertension, tachycardia, emesis, and presyncope.

JOINT545

Relevance of growth differentiation factor 15 in weight management

Haitham Abu-Lebdeh[1] & Hassan Heshmati[2]
[1]Mayo Clinic, Division of Endocrinology, Diabetes, Metabolism and Nutrition, Rochester, United States; [2]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, United States

Introduction
Growth differentiation factor 15 (GDF15), a peptide hormone produced by the placenta during pregnancy but also by several other organs (e.g., prostate, bladder, kidney, pancreas, and endometrium), is a member of the transforming growth factor-β superfamily. The gene of GDF15 is located on chromosome 19. The mature GDF15 has 112 amino acids and binds to glial cell-derived neurotrophic factor family receptor alpha-like. GDF15 is involved in the maintenance of homeostasis and plays an important role in several pathological conditions (e.g., cardiovascular diseases, autoimmunity, obesity, diabetes, and cancer). This review presents an update on the relevance of GDF15 in weight management in patients with obesity, heart failure, and cancer.
Methods
A systematic search of literature was conducted using the search terms growth differentiation factor 15, pregnancy, heart failure, autoimmunity, anorexia, obesity, diabetes, cancer, and weight management.
Results
The median serum GDF15 level in control subjects is around 680 pg/ml and increases with aging. There is an increase in GDF15 secretion under stressful conditions (e.g., pregnancy, inflammation, myocardial ischemia, pulmonary diseases, diabetes, and cancer). GDF15 plays an important role in the maintenance of cell and tissue homeostasis. It has anti-inflammatory and immunomodulatory properties. GDF15 regulates appetite and body weight by inducing anorexia which results in reduction of food intake. In a study of non-obese monozygotic twin pairs, serum GDF15 levels were negatively correlated with body mass index (BMI) within twin pairs, meaning that subjects with lower serum GDF15 levels had a higher BMI than their corresponding twin. In metformin-treated patients with or without type 2 diabetes, metformin stimulates GDF15 production, contributing to the weight-loss property of metformin. The increased serum GDF15 levels in patients with heart failure or cancer contribute to cachexia (anorexia and weight loss). In view of the above GDF15 properties, GDF15 analogs and antagonists can be used in the weight management of obesity (reduction of body weight by inducing anorexia using GDF15 analogs) and heart failure or cancer (reduction of cachexia by improving appetite and increasing body weight using GDF15 antagonists).
Conclusion
GDF15, a hormone synthesized by the placenta during pregnancy and several other organs, is involved in multiple physiological and pathological conditions. It contributes to the regulation of appetite and body weight. GDF15 induces anorexia and this property can be used in the weight management of obesity and cardiac or cancer cachexia with its analogs and antagonists.

Impact of neurodegeneration on GLUT4 activity in experimental dm rats brain hyppocampus

Mukhammadjon Mustafakulov[1], Tokhir Ishanhodjaev[1], Gulnora Artykbaeva[1], Talat Saatov[1], Zulaykho Shamansurova[1,2] & Ashok Srivastava[3]

[1]Institute of Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan; [2]Central Asian University, Endocrinology, School of Medicine, Tashkent, Uzbekistan; [3]University of Montreal, Montreal, Canada

Introduction
.Cell membrane function abnormalities were seen in type 2 Diabetes Mellitus (DM) and leads to abnormal insulin signaling transduction followed decreased activity of GLUT4. Neurodegeneration also affects brain function by affecting GLUT4 activity. We studied GLUT4 activity in rats brain hyppocampus in rats with experimental streptozotocine induced DM in compare with additional neurodegeneration state.
Material and Methods
Adult 12 week aged rats were divided into 3 groups, experimental streptozotocine induced DM fed standard chow (DM) and fed with high fat diet and neurotoxin (DM+N), also control group without DM. Experimental DM development were evaluated in blood samples taken from tail vien by glucometer. After 12 weeks experiments rats were sacrificed and brain samples were flash frozen for further measure of GLUT4 acitity in extracted hyppocampus by ELISA.
Results
DM rats blood glucose level were increased 2.1 times in compare with control rats and confirm streptozotocin induced DM model. Blood glucose level were higher by 2.7 times in DM+N group and suggested about worsening of glycemia by accompanied neurodegeneration. Activity of GLUT4 in brain hyppocampus were decreased by 15% in DM and 19% in DM+N group in compare with control rats suggesting about poor insulin signaling in brain hyppocampus and were more worsen in combination of neurodegeneration.
Conclusion
Insulin signaling transduction were affected in experimental DM and accompanied with decreasing of GLUT4 activity in brain hyppocampus. Neurodegeneration more worsen insulin signaling transduction and more affects GLUT4 activity in rats brain hyppocampus.

Influence of vitamin d deficiency in patients with obesity on thyroid gland and liver function

Solomiia Plakhetko[1] & Alina Urbanovych[1]
[1]Lviv National Medical University, Lviv, Ukraine

Background and aims
Obesity is one of the most common medical and social issues influencing the onset and progression of type 2 diabetes mellitus, metabolic-associated fatty liver disease, arterial hypertension, polycystic ovary syndrome, obstructive sleep apnea, and certain types of cancer. Currently, the role of vitamin D (VD) in the course of obesity is being investigated, and the influence of VD supplementation on this pathology is being analyzed. Additionally, a correlation has been observed between VD deficiency and thyroid gland and liver function. Our research aimed to study correlation between VD insufficiency/deficiency and insulin resistance in patients with obesity, depending on body mass index (BMI) and waist circumference (WC), and to determine their association with thyroid gland and liver function.
Materials and Methods
Our study included 30 individuals aged 22 to 64 years, including 23 individuals with alimentary-constitutional obesity (BMI 35.3 ± 5.2 kg/m^2) and 7 overweight individuals (BMI 27.1 ± 2.3 kg/m^2) and no history of prediabetes or diabetes mellitus. HOMA index, vitamin D (25(OH)D), thyrotropin-stimulating hormone (TSH), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) levels were obtained as well as anthropometric parameters, including body weight, height, and waist circumference (WC).
Results
The study results indicated that VD deficiency was more pronounced in patients with obesity. Levels of 25(OH)D, HOMA index, TSH, and ALT achieved statistical significance in obese patients (24.6 ± 13.6 ng/ml; 6.9 ± 4.69; 4.2 ± 3.5 μIU/ml; 47.0 ± 28.1 U/l,respectively) compared to overweight individuals (27.0 ± 7.8 ng/ml; 5.89 ± 4.1; 2.77 ± 1.87 μIU/ml; 43.7 ± 27.7 U/l,respectively). Additionally, WC was significantly higher in obese patients (107 ± 24 cm) compared to the overweight group (82.5 ± 8.5 cm) ($P < 0.05$). Serum 25(OH)D negatively correlated with BMI ($r = -0.17$, $P < 0.05$), whereas HOMA index positively correlated with BMI ($r = 0.31$, $P < 0.05$). Serum 25(OH)D negatively correlated with HOMA index ($r = -0.19$, $P < 0.05$) and with WC ($r = -0.11$, $P < 0.05$). Serum 25(OH)D negatively correlated with TSH ($r = -0.23$, $P < 0.05$), as well as ALT negatively correlated with 25(OH)D ($r = -0.22$, $P < 0.05$).
Conclusion
Our study demonstrates a high prevalence of vitamin D deficiency in patients with obesity and it is also correlated with thyroid gland and liver dysfunction. The intensity of hypovitaminosis of vitamin D is aggravated with higher levels of HOMA index and higher degrees of obesity. Effective treatment of VD deficiency can improve clinical outcomes of obesity and metabolic disorders associated with it.

Psychological profile of the obese diabetic patient

Syrine Trabelsi[1], Rym Ben Othman[1], Yesmine Jallouli[1], Ramla Mizouri[1], Rim Rachdi[1], Berriche Olfa[1], Faten Mahjoub[1], Ben Amor Nadia[1] & Jamoussi Henda[1]
[1]National Institut of Nutrition, A, Tunis, Tunisia

Introduction
Obesity is a chronic disease defined by excessive adipose tissue deposition that can be detrimental to health. The "diabetes-obesity" association is very frequent, resulting in an exacerbation of psychological complications.
Objective
Compare psychological profiles in a population of type 2 diabetics according to their weight status.
Methods
This was a cross-sectional study of 254 diabetic patients. Data were collected on the basis of a pre-established questionnaire, anthropometric measurements, the PSS4 Score to assess stress levels, and HAD scales assessing anxiety and depression.
Results
The population was divided into two groups: 179 obese patients (obese group) and 75 with a normal BMI (non-obese group). Obesity was present in 46.2% of male patients and 78.8% of female patients. The mean age was 58.66 ± 8.7 years for the obese group vs 59.04 ± 8.7 years for the non-obese group. Diabetes duration was 13.94 ± 8.4 years in the obese group and 13.05 ± 7.7 years in the non-obese group. Patients in the obese group perceived more stress than those in the non-obese group (mean PSS4 scores were 7.65 ± 4.08 and 6.64 ± 4.25 respectively). The mean HAD anxiety score was 9.6 ± 4.9 in the obese group vs 8.63 ± 5.1 in the non-obese group ($P = 0.16$). For the HAD depression score, the mean was 9.3 ± 5.1 in the obese group vs 7.9 ± 5.3 in the non-obese group ($P = 0.06$).
Conclusion
Given the psychological impact of obesity and diabetes as two chronic diseases, psychosocial support is needed to help obese diabetics live better with their disease and improve their quality of life.

JOINT2015

Success rates of pre-pregnancy and gestational obesity interventions in preventing childhood obesity: a comprehensive review

Dina Fawzy[1], Shaymaa Elsayed[1], Ashraf Soliman[2], Ahmed Elawwa[1], Fawzia Alyafei[2], Nada Alaaraj[2] & Noor Hamed[2]
[1]Pediatric Endocrinology and Diabetology Unit, Alexandria University, Pediatric Endocrinology and Diabetology Uni, Alexandria, Egypt;
[2]Department of Pediatrics, Hamad General Hospital, Doha, Qatar

Background
Childhood obesity is a global epidemic with roots in maternal health during and before pregnancy. Interventions targeting pre-pregnancy obesity, gestational weight gain (GWG), and related maternal factors have been explored to mitigate risks and break the intergenerational cycle of obesity.
Objective
To review evidence on the success rates and benefits of interventions addressing pre-pregnancy and gestational obesity in preventing childhood obesity, focusing on their outcomes and effectiveness.
Methods
A review of 20 studies (2000–2024) including randomized controlled trials, observational studies, and systematic reviews was conducted. These studies examined lifestyle, behavioral, and system-level interventions during the prepregnancy, pregnancy, and postpartum periods. Success rates were calculated based on study outcomes.

Results
Lifestyle Interventions: Achieved an average success rate of 65%, effectively reducing GWG, gestational diabetes mellitus (GDM), and improving maternal metabolic health. Examples include the RADIEL Study (728 women) and the Maternal Obesity Management (MOM) Trial (60 women). Behavioral and mHealth Interventions: Demonstrated an average success rate of 60%, promoting healthy behaviors and improving glucose tolerance during pregnancy. The VACOPP study (185 participants) and the "mami-educ" mHealth program showed promising outcomes. Early-Life Interventions: Multifactorial strategies during the first 1,000 days had an average success rate of 45%, mitigating childhood obesity risks through integrated care. However, these interventions required sustained postpartum support for long-term effectiveness. Childhood Obesity Prevention: Interventions focusing on both prenatal and early-life factors showed a success rate of 40% in reducing childhood obesity prevalence, highlighting the need for continuous care.
Conclusions
Interventions targeting maternal prepregnancy and gestational health demonstrate moderate to high success rates, with the greatest effectiveness observed in structured lifestyle programs. Sustained efforts into the postpartum period and scalable, personalized interventions are critical for long-term success in reducing childhood obesity.

Lactic acidosis secondary to metformin toxicity :a case report

Hemmat El Haddad[1], Manal Abufarha[1], Nermine Zawilla[1], Ahmed Fayed[1], Mohamed Magdy[1], Randa Salam[2], Mohamed Mahmoud[1], Noha Tarek[2], Salma Mohamed[1], Tasneem Halaby[1,2], Sara Asal[1], Ahmed Atef[1], Alla Abdallah[1] & Ayat Magdi[2]
[1]Cairo University, Cairo, Egypt; [2]Cairo University, Cairo, Egypt

Introduction
Metformin is an oral antidiabetic drug in the biguanide class. It is the first-line drug of choice for the treatment of type 2 diabetes. The most common symptoms following overdose appear to include vomiting, diarrhea, abdominal pain, tachycardia, drowsiness, and, rarely, hypoglycemia. The major potentially life-threatening complication of Metformin overdose is metabolic acidosis. We report a case of fatal Metformin toxicity following an acute intentional Metformin intoxication.
Case report
18 years old female presented to the emergency department three hours after a suicide attempt with 30 grams of metformin, severely agitated, confused. With severe abdominal pain associated with persistent vomiting Examination Pulse: 120/minute, BP: 80/60mmHg, Temprature was 37.0°C. and respiratory rate of 28. cardio-respiratory system was normal; her abdomen was soft and non-tender. Arterial blood gas analysis on admission showed a profound lactic acidosis:pH 6.8 (7.38 to 7.42); pCO2 :27 (35-45Mmhg), pO2:99 bicarbonate 4.2 (22-28 mmol/L)and lactate >15 (<1 mmol/l)Blood test results at presentation HB: 11.2g, platelet 131 (150-450) Creatinine 1.8mg (0.74 to 1.35) family members took her to toxicology emergency unit where gastric lavage was done, oral charcoal and intravenous fluids were given. During her ICU stay Day 1 The patient had severe lactic acidosis, for which she received sodium bicarbonate (200 ml) infusion. She was resuscitated by intra-venous fluids (Ringer acetate) and put on noradrenaline with no response so adrenaline was added Day 2 Lactic acidosis was persistent and severe so she received one hemodialysis session after nephrology consultation. Day 3 The patient was off adrenaline but withdrawl of nor-adrenaline failed so dobutamine infusion was added supported by the data detected in echocardiography EF 20%, akinetic whole septum, hypokinetic other whole segments sparing apical segments (apical segments contract better than basal segments). Day 4 The patient developed one attack of convulsions generalized tonic seizures followed by post-ictal confusion. Neurology consultation revealed unremarkable MRI with diffusion and EEG levetiracetam 500 was given twice daily Day 5 The patient was off nor-adrenaline then off dobutamine with intact peripheral pulsations and normal blood pressure echocardiography was normal. EF 60%.
Conclusions
metformin overdose, diagnosis and timely intervention in the form of hemodialysis for metabolic acidosis, coupled with sufficient hemodynamic resuscitation. Hence, emergency clinicians and toxicologists must maintain a high level of suspicion for drug poisoning in any patient presenting with marked metabolic acidosis or displaying symptoms related to the gastrointestinal and respiratory systems.

Prevalence and associated factors of obesity among smokers

Dorra Ben Salem[1], Cyrine Bennasrallah[2], Wafa Dhouib[2], Mariem Kacem[2], Imen Zemni[2], Ines Bouanene[2], Asma Sriha[2], Hela Abroug[2] & Manel Ben Fredj[2]
[1]CHU Fattouma Bourguiba, Department of Preventive and Community Medicine, Monastir, Tunisia; [1]CHU Fattouma Bourguiba, Department of Preventive and Community Medicine, Monastir, Tunisia

Introduction
The association between obesity and smoking is gaining increasing interest in public health. The aim of our study was to investigate the factors associated with obesity among smokers.
Materials and Methods
A cross-sectional analytical study was conducted at the smoking cessation clinic of CHU Fattouma Bourguiba in Monastir, including 253 male smokers who attended consultations in 2023. Anthropometric measurements were recorded, and spirometry was performed for each participant.
Results
The mean age was 48.62 $\pm$ 16.69 years. More than a quarter of the participants were sedentary (27.6%), and 19% consumed alcohol. The average cigarette consumption was 34.61 $\pm$ 32.13 pack-years. The mean age at first cigarette use was 17.16 $\pm$ 9.82 years, while the mean age at the onset of regular smoking was 19.92 $\pm$ 7.23 years. The average pulmonary age, as measured by spirometry, was 65.27 $\pm$ 21.24 years, with only 42.3% of participants having normal spirometry results. The mean body mass index (BMI) was 24.71 $\pm$ 4.46 kg/m^2. Overweight and obesity were observed in 30% and 13.8% of cases, respectively. Obesity was more prevalent among sedentary individuals (22.4% vs. 9.7%, $P = 0.009$) and alcohol consumers (26.1% vs. 10.7%, $P = 0.006$). Higher BMI was correlated with a later onset of smoking ($P = 0.04$) and an increased pulmonary age ($P = 0.001$).
Conclusion
The coexistence of obesity and smoking is common, highlighting the need for a holistic health approach that addresses both issues in an integrated manner.

JOINT3857

Assessment of anthropometric and body composition parameters of diabetologists pan india

Bharat Saboo[1,2] & Sakshi Mhatre[3]
[1]Prayas Diabetes Center, Diabetes and Obesity, Indore, India; [2]Prayas Diabetes Center, Indore, India; [3]Inbody, Mumbai, India

Aim
This study aims to evaluate the anthropometric and body composition parameters of diabetologists across India, focusing on gender-based variations and their potential health implications. The research hypothesizes that professional demands and lifestyle factors may influence these parameters, affecting overall health and metabolic risk.
Materials and Methods
A total of 100 practising diabetologists, equally distributed by gender (50 males and 50 females), were recruited for this cross-sectional study. Anthropometric and body composition measurements were obtained using the InBody380 bioelectrical impedance analysis device. The parameters assessed included height, weight, Body Mass Index (BMI), Percent Body Fat (PBF), and Skeletal Muscle Index (SMI). To ensure consistency and accuracy in data collection, participants adhered to standardized pre-measurement protocols, which included fasting for at least two hours and abstaining from exercise or alcohol consumption before the assessment.
Results
The study revealed significant gender-based differences in anthropometric and body composition parameters: Males: Average height: 168.9 cm Average weight: 78.08 kg BMI: 27.4 kg/m^2 PBF: 31.7% SMI: 7.5 Females: Average height: 159.8 cm Average weight: 68.29 kg BMI: 26.8 kg/m^2 PBF: 40.11% SMI: 6.28 Both male and female diabetologists presented BMI values within the overweight category. The elevated PBF observed in females suggests a higher predisposition to metabolic complications, while the lower SMI reflects physiological differences that may necessitate targeted interventions.
Conclusion
This study underscores the importance of regular health assessments and personalized lifestyle modifications for healthcare professionals, particularly diabetologists. The sedentary and demanding nature of their professional roles contributes to increased health risks, necessitating proactive measures such as dietary adjustments and structured exercise regimens. Addressing these health challenges is

crucial not only for the well-being of the healthcare providers themselves but also for reinforcing their role as exemplars of healthy living for their patients. A holistic approach to health management among diabetologists is essential to mitigate risks and promote overall well-being.

Avdalbekyan, Yerevan, Armenia; [5]NWSMU named after I.I. Mechnikov, Saint-Petersburg, Russian Federation; [6]Association "Eurasian Association of Internal Medicine", Saint-Petersburg, Russian Federation

Aim
To investigate the characteristics of metabolic status in individuals with polyvascular disease (PVD).
Materials and Methods
KAMMA (NCT05189847) is an international register of real clinical practice, comprising 28 centres across the Russian Federation, the Republic of Kazakhstan, the Republic of Uzbekistan and the Republic of Belarus. The register includes 3059 individuals over the age of 18 with confirmed atherosclerosis in two or more arterial basins, as well as one or more atherosclerosis risk factors. The ankle-brachial index (ABI) was measured for all the patients in the study, either manually or automatically. The level was considered to be low if it was $\leq$0.9, normal if it was between 0.9 and 1.4, and high if it was $\geq$1.4.
Results
The mean age of the people included in the study was 66 years [59-72], and 60.3% of them were men. The most common comorbidities were hypertension in 96%, coronary heart disease in 94.8%, history of myocardial infarction in 47%, heart failure in 81%, chronic kidney disease (CKD) $\geq$C3A stage in 24.2%, and chronic lower-extremity arterial insufficiency in 21%. In the whole population, the mean body mass index was 29.4 [26.0;32.5] kg/m^2, corresponding to overweight; waist circumference was 97 [88;105] cm, corresponding to abdominal obesity. 27% of patients had dyslipidemia with low-density lipoproteins (LDL) elevation $>$ 4.9 mmol/l,3.4% of patients had familial hypercholesterolemia. In most cases, LDL target levels were not achieved despite treatment with statins (92.8%). Alternative hypolipidemic drugs (omega-3 polyunsaturated fatty acids 11.2%, ezetimibe 8.4%, fibrates 2.9%, antibodies to PCSK9 1.4%) were used less frequently. 10.2% of patients had prediabetes, while 32.2% had type 2 diabetes mellitus (DM), with a mean glycated hemoglobin level of 6.4 [5.7;7.2] %. Patients with type 2 DM had lowered ABI more often than patients without type 2 DM (47.6% vs 36.1%, $P <$ 0.001). In 7% of patients with type 2 DM, the course of the disease was complicated by the development of diabetic foot. Among them, lowered ABI (76.8% vs 38.9%, $P <$0.001), CKD C3 (14.5% vs 4.8%, $P <$0.001) and C4 (5.8% vs 0.6%, $P <$0.001) stages were significantly more common.
Conclusion
The complex of identified metabolic disorders, together with inadequate control of key risk factors (presence of overweight, abdominal obesity, dyslipidemia, type 2 DM, prediabetes), may contribute to the development and accelerated progression of PVD and potentially have a negative impact on its outcome.

Risk factors for metabolic disorders in patients with polycystic ovary syndrome

Yesmine Elloumi[1], Abbes Wissal[1], Mouna Elleuch[1], kouloud boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], mohamed abid[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
Polycystic ovary syndrome (PCOS) is a common endocrine disorder often associated with various metabolic disturbances. The presence of metabolic disorders, such as diabetes, dyslipidemia, and hyperuricemia, may complicate the clinical management of PCOS patients. This study aims to compare the clinical and metabolic profiles of PCOS patients with and without these metabolic complications, providing insights into their potential impact on the disease.
Methods
A retrospective comparative study was conducted on 49 patients followed for PCOS in the Endocrinology Department at Hedi Chaker University Hospital, Sfax, Tunisia. The patients were classified into two groups: Group 1 included 13 patients with PCOS and metabolic disorders (diabetes, dyslipidemia, hyperuricemia), while Group 2 consisted of 36 patients without such disorders.
Results
The mean BMI was 29.4 in Group 1 (G1) vs 25.2 in Group 2 (G2); $P = 0.001$. Obesity or overweight was observed in 77% of G1 patients vs 47% of G2 patients; $P = 0.06$, with an android type distribution in 54% of cases. Acanthosis nigricans was found in 46% of G1 patients vs 3% of G2 patients; $P = 0.001$. Menstrual cycle disorders were reported by 77% of G1 patients and 83% of G2 patients; $P =$ 0.9, including amenorrhea in 18 cases and oligomenorrhea in 22 cases. Infertility or subfertility was found in 22% of G1 patients vs 26% of G2 patients; $P = 0.7$. Hirsutism was present in 38% of G1 patients vs 47% of G2 patients; $P = 0.5$. Hormonal analysis revealed an average LH of 12 IU/ml and an average FSH of 7 IU/ml, with no significant differences between the two groups. The average estradiol level was 38 pg/ml, while the average testosterone level was 1.11 ng/ml. Hyperprolactinemia was detected in 14 patients (28%), with 12 cases in G1.
Conclusion
Aside from abnormalities related to insulin resistance, there were no statistically significant differences in the clinical and hormonal profile of this syndrome in the presence or absence of metabolic disorders.

Role of spermidine in longevity

Reinhart Jarisch[1] & Hassan Heshmati[2]
[1]Floridsdorf Allergy Center, Vienna, Austria; [2]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, United States

Introduction
Aging is a natural universal and irreversible phenomenon. It is associated with decreased autophagic activity. Spermidine is a naturally occurring polyamine that was discovered in human semen in 1678. Its sources are endogenous (e.g., synthesis by gut microbiome) and exogenous (e.g., dietary intake and supplements). Spermidine is involved in various physiological processes including regulation of autophagy and maintenance of cellular homeostasis. Spermidine administration may be beneficial in the fight against aging. This review presents an update on the role of spermidine in longevity.
Methods
A systematic search of literature was conducted using the search terms spermidine, autophagy, aging, and longevity.
Results
Aging is associated with a progressive deterioration of the cell and organ functioning and the occurrence of several age-related diseases responsible for increased mortality. Autophagy, a major protein turnover pathway that maintains cellular homeostasis under stress conditions, decreases in aging individuals, impacting the longevity. Spermidine plays an important role in cellular growth, regeneration, and regulation. It stimulates autophagy through the inhibition of several acetyltransferases, has anti-inflammatory and antioxidant properties, and positively affects the cell cycle. Stimulation of autophagy is the main mechanism of action of spermidine at the molecular level. Spermidine has the potential to prevent or postpone the occurrence and severity of various age-related diseases (e.g., ischemic heart disease, stroke, chronic obstructive pulmonary disease, cancer, respiratory infection, type 2 diabetes, osteoporosis, and dementia), decrease mortality, and increase longevity. An association between high dietary spermidine intake and reduced mortality has been reported in a cohort of 1,770 healthy subjects aged 39-67 years with a medium follow-up of 13 years. The median of serum spermidine level in normal subjects is around 25 ng/ml and the level declines with aging. Considering the physiological properties of spermidine, foods with high contents of spermidine (e.g., plant-derived products and aged cheese), the Mediterranean diet, and spermidine supplements (spermidine in capsule) may potentially be beneficial for healthy aging and increased longevity. However, the safety of chronic spermidine administration should be further investigated before clinical guidelines are established.

Conclusion
Spermidine regulates a wide range of biochemical and physiological aging processes. Its anti-aging properties is mainly through the stimulation of autophagy. Spermidine can prevent or postpone the occurrence and severity of several age-related diseases. Diet rich in spermidine and spermidine supplements can be beneficial for healthy aging and increased longevity. However, more investigations are necessary to better define the risks and benefits of long-term spermidine administration.

Metabolic syndrome and cancer metabolic syndrome and cancer

Dhoha Ben Salah[1], Oumaima Dimassi[1], Khouloud Boujelben[1], Nada Hassairi[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Department of Endocrinology Hedi Chaker Hospital, Sfax, Tunisia

Introduction
Cancer is currently one of the leading causes of mortality worldwide. The aim of our study was to describe the epidemiological and clinical profile of cancer in patients with metabolic syndrome.
Methods
This was a retrospective study that included 16 patients with metabolic syndrome and cancer, collected between 2012 and 2021 in the Endocrinology Department of Sfax.
Results
Our study included 16 patients with a sex ratio of 0.45. The mean age at cancer diagnosis was 58.8 $\pm$ 14.8 years (range: 28–82). None of the patients had a family history of cancer. Hypertension was present in 81.3% of cases, diabetes in 62.5%, and established cardiovascular disease in 12.5%. The mean BMI was 29.25 $\pm$ 7.4 kg/m^2 (range: 20.48–54), with obesity found in 31.3% of patients. Android obesity was present in 81.8% of women vs only 20% of men. The mean systolic blood pressure was 139 $\pm$ 22.52 mmHg (range: 120–190), and the mean diastolic blood pressure was 82 $\pm$ 12.9 mmHg (range: 60–110). Mean fasting blood glucose was 12.23 mmol/l,mean HDL cholesterol was 0.97 $\pm$ 0.34 mmol/l,and mean triglycerides were 2.03 $\pm$ 1.13 mmol/L. Among the 16 patients: 6 had breast cancer, 2 prostate cancer,2 adrenocortical carcinoma, lung cancer, 1 renal cancer, 1testicular cancer, 1 thyroid cancer, 1 colorectal cancer and 1 lymphoma.
Discussion
The pathophysiological link between cancer and metabolic syndrome remains poorly understood. However, some studies implicate excessive caloric intake as a trigger for reactive oxygen species, which exert mutagenic effects.

Severe form of lipoedema and obesity, therapeutic challenge: report of a rare case

Natasha Nedeska Minova[1 2], Cvetanka Volkanovska Ilijevska[3], Valentina Velkoska Nakova[2], Igor Peev[4], Irena Gigovska Dimova[1] & Goce Hristov[2]
[1]General City Hospital 8 th September, Department of Endocrinology and Diabetes, Skopje, Macedonia; [2]Faculty of Medical sciences, Goce Delcev University, Stip, Macedonia; [3]University clinic of Endocrinology, Skopje, Macedonia; [4]University Clinic for Plastic and Reconstructive surgery, Skopje, Macedonia

Objective
Lipoedema is a systemic disease with disssarenged accumulation and distribution of fat tissue, due to disturbed fat metabolism. It was first introduced as a separate clinical entity in the United States in 1940. The cause is unknown, but is bealieved genetic factors to be involved. Mostly clinically misdiagnosed, it presents as lipoedema, lipolymphedema, or combined with obesity.
Case
We present a case of a 42-year-old woman introduced in the endocrinology department due to overweight with a BMI of 93.6kg/m^2 and disproportionate accumulation on fat tissue on both legs. It was reported present parental and twin sister obesity. All efforts for hygiene-dietary modalities were insufficient. According to the clinical findings, it is combined type 2 and 3 of lobular lipoedema in stage IV, with obesity and comorbidities. Treatment with low-calorie diet, medicines and bariatric surgery was implemented. After that therapeutic and reconstructive plastic surgery was approached. Due to a weight regain, GLP1-RA was started, resulting with reduction of body weight. The overall treatment resulted with a weight loss of 91kg and a significant improvement health condition and quality of life.
Conclusion
The etiology and pathophysiology of lipedema remain unclear. The case at hand shows that there are huge therapeutic challenges for such a complex case. We show that this kind of multidisciplinary approach is necessary and it was effective, improved the quality of life and prevented comorbidities.
Key words
lipoedema stage 4, obesity, Bariatric surgery, plastic surgery, GLP1-RA.

JOINT1608

Clinical case of hypothalamic obesity following craniopharyngioma removal

Laura Ebanoidze[1], Mariia Berlovich[1], Daria Lisina[1], Ekaterina Pigarova[1], Larisa Dzeranova[1] & Svetlana Vorotnikova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Hypothalamic damage resulting from craniopharyngiomas (CP) and their treatment has been widely associated with hyperinsulinemia, increased appetite due to leptin resistance, and reduced energy expenditure, leading to diminished physical activity. Dysfunction of the hypothalamus, often accompanied by pituitary hormone deficiencies, predisposes up to 50% of affected patients to the development of hypothalamic obesity (HO), typically characterized by rapid and significant weight gain.
Materials and Methods
In May 2020, an 18-year-old female patient S. with a body mass index (BMI) of 25.7 kg/m^2 underwent stalk CP resection at the N.N. Burdenko National Medical Research Center of Neurosurgery. Postoperatively, she was diagnosed with panhypopituitarism, including central diabetes insipidus, secondary hypocortisolism, hypothyroidism and hypogonadism. Hormone replacement therapy was initiated with desmopressin 0.1 mg three times daily, hydrocortisone 20 mg/day, levothyroxine 100 mg/day, and estradiol gel + dydrogesterone (1/10mg/day). In December 2020, the patient experienced a decline in health, presenting with nausea, vomiting and a decrease in sodium to 105 mmol/l(136-145mmol/L). She was urgently admitted to the intensive care unit, where rapid correction of hyponatremia led to central pontine and extrapontine myelinolysis in the context of panhypopituitarism. The patient developed bilateral supranuclear paresis of the facial, masticatory and bulbar muscles along with tetraplegia. One year later, the patient reported increased appetite and a 19 kg weight gain. Metformin therapy (1000mg/day) was prescribed. In 2022, during hospitalization at the Endocrinology Research Centre, insulin resistance was confirmed (HOMA index: 2.82), and her BMI had increased to 33.9 kg/m^2. She was referred to a dietitian, who recommended a hypocaloric diet and increased physical activity. In November 2023, clinical and laboratory tests confirmed pharmacological compensation of panhypopituitarism. MRI showed no signs of CP recurrence. However, the patient experienced nocturnal awakenings to eat, leading to a diagnosis of eating disorder (ED) with pansyndromal overeating. Psychoanaleptics were added to the regimen, but weight gain continued (BMI: 35.9kg/m^2).
Results
This case underscores the complexities in managing HO, where despite the optimization of hormone replacement therapy, caloric restriction, increased physical activity, and pharmacological control of the ED, the patient was unable to achieve a normal body weight.
Conclusions
The identification of etiological factors contributing to HO, along with the development of novel or combined therapeutic strategies, could provide a

multifaceted approach to managing hyperphagia, insulin resistance, hypopituitarism and psychosocial rehabilitation. Such interventions may lead to more effective and sustainable weight loss outcomes and help minimize the risk of long-term complications.

Determinants of advanced non-alcoholic fatty liver disease steatosis in the obese women: results of a tunisian study

Sana Khamassi[1], Fatma Boukhayatia[1], Yacoub Haythem[2], Marouani Nouha[1], Haifa Abdesselem[1], Emna Bornaz[1], Kamilia Ounaissa[1], Hedfi Imene[3], Saida Boumefteh[1], Feika Ben Mami[3] & Chiraz Amrouche[1]
[1]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia; [2]Rabta Hospital, Gastroenterology Service B, Tunis, Tunisia; [3]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases C, Tunis, Tunisia

Background
Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease, closely linked to obesity and diabetes. Due to its silent nature, it remains underdiagnosed. The aim of our study was to screen for NAFLD in a population of obese women and identify the factors associated with its severity.
Methods
This is a cross-sectional study conducted on 40 obese female patients. Physical activity level was evaluated using the Ricci and Gagnon questionnaire. NAFLD screening was performed using Fibroscan. Advanced steatosis was defined as a stage of S2 or higher, and advanced fibrosis was defined as a stage of F2 or higher.
Results
Mean age was 43.56 $\pm$ 12.75 years. The majority of patients were inactive (65%). The mean duration of obesity was 19.95$\pm$12.93 years. The mean BMI was 40.36$\pm$7.17 kg/m^2, with morbid obesity observed in 45% of the patients. Abdominal obesity was present in all patients, with a mean waist circumference of 119.80 $\pm$ 14.61 cm. Steatosis was found in 75% of the patients: 17.9% at stage S1, 17.9% at stage S2, and 38.5% at stage S3. As for fibrosis, it was present in 90% of the patients: F1 in 52.5%, F2 in 15%, F3 in 5%, and F4 in 17.5%. Patients with advanced steatosis were mostly inactive (83% vs 41%; P = 0.009). A stage S2 or higher was associated with the duration of obesity (24.05$\pm$13.87 years vs 14.31$\pm$9.19 years; P = 0.02) as well as the presence of metabolic syndrome (61% vs 24%; P = 0.019). Anthropometric data revealed that severe steatosis was associated with higher BMI (43.31$\pm$7.43 kg/m^2 vs 37.00$\pm$5.00 kg/m^2; P = 0.004), increased waist circumference (125.09$\pm$14.70 cm vs 112.65$\pm$11.34 cm; P = 0.006) and waist-to-height ratio (0.79$\pm$0.11 vs 0.69$\pm$0.08; P = 0.006), higher fat mass (54.63$\pm$12.30 kg vs 43.48$\pm$8.66 kg; P = 0.003) and a higher visceral fat percentage (30% vs 0%; P = 0.03). Furthermore, advanced steatosis was associated with higher ALT levels (26.26 $\pm$ 8.64 IU/lvs 18.00 $\pm$ 4.58 IU/L; P = 0.001), a higher GGT levels (35% vs 6%; P = 0.038) and a lower platelet count (283.62 $\pm$ 74.45 x1000/mm^3 vs 342.56 $\pm$ 75.84 x1000/mm^3; P = 0.024).
Conclusion
Our study emphasizes the need for targeted screening and interventions to manage NAFLD focusing on risk factor monitoring and an active lifestyle.

Impact of SGLT-2 inhibitors on metabolic and cardiovascular health: a comparative analysis of patients with and without diabetes

Liana Jashi[1], Tamar Peshkova[2], Koba Kamashidze[3], tamar shervashidze[4], Eter Margalitadze[2], Miranda Basiladze[1], lela Beridze[2] & Ana Abashidze[5]
[1]AVICENNA – Batumi Medical University, Batumi, Georgia; [2]Batumi Shota rustaveli State University, Batumi, Georgia; [3]Univesity of Georgia, T'bilisi, Georgia; [4]David Agmashenebeli University of Georgia, Tbilisi, Georgia; [5]Tbilisi State University, T'bilisi, Georgia

Background
Sodium-glucose cotransporter-2 (SGLT-2) inhibitors, particularly dapagliflozin, have shown promise in improving glycemic control, weight reduction, and cardiovascular function in patients with diabetes mellitus (DM). However, the differential effects of dapagliflozin in diabetic vs non-diabetic individuals, as well as potential gender-based variations in treatment response, remain under investigation. This study compares the effects of dapagliflozin on key metabolic and cardiovascular parameters—fasting glucose, postprandial glucose, HbA1c, body mass index (BMI), weight loss, and ejection fraction (EF)—in both diabetic and non-diabetic patients, with a particular focus on gender differences.
Methods
A cohort of 17 diabetic patients and 18 non-diabetic individuals were treated with dapagliflozin over three months. Baseline and post-treatment measurements were collected for fasting glucose, postprandial glucose, HbA1c, BMI, weight loss, and EF. Statistical analyses compared the outcomes between diabetic and non-diabetic groups and evaluated gender-specific differences in response to treatment.
Results
Patients with Diabetes: Dapagliflozin significantly reduced fasting glucose (8.9–12.7 mmol/lto 5.8–7.8 mmol/l)and postprandial glucose (8.9–14.8 mmol/lto 6.7–9.9 mmol/L). HbA1c levels improved by 0.5%–1.2%. Weight loss ranged from 1.5–3.2 kg, with men experiencing greater reductions. EF increased by 2%–6%, indicating improvements in cardiac function. Patients without Diabetes: Minimal changes were observed in fasting and postprandial glucose levels. HbA1c remained stable (4.3%–5.5%). Weight loss was less pronounced (0.2–2.1 kg), while EF improved by up to 8%, likely reflecting better baseline cardiac function. Gender Differences: Men exhibited more significant reductions in fasting glucose and BMI. Women showed greater improvements in postprandial glucose, with stable cardiovascular benefits.
Conclusions
Dapagliflozin offers significant improvements in glycemic control, weight loss, and cardiac function in diabetic patients, while non-diabetic individuals experience notable cardiovascular benefits and modest weight loss. Gender differences in response suggest that men benefit more from reductions in fasting glucose and BMI, while women show more significant improvements in postprandial glucose levels. These findings support the broader use of dapagliflozin for managing cardiometabolic health beyond diabetes.

Evaluation of patients undergoing bariatric surgery: our experience

Óliver Quintero Rodríguez[1], Selena Rodriguez Fernandez[1], Kevin David Díaz Gorrín[1], Javier Panizo Fra[1], Ana Paola León Ocando[1], Laura Mesa Suárez[1], Elena Rodríguez Sosa[1], Patricia León González[1], Macarena Sánchez-Gallego Alonso[1] & Patricia Cabrera García[1]
[1]Hospital Universitario de Canarias, Endocrinology and Nutrition, San Cristóbal de La Laguna, Spain

Introduction
According to the World Health Organization (WHO), obesity is considered the pandemic of the 21st century. Currently, 1 in 7 people worldwide suffer from obesity, and according to the 2023 World Obesity Atlas, it is projected to affect 1 in 4 people by 2035.
Objectives
To describe the characteristics of patients with obesity who underwent bariatric surgery and attended Nutrition consultations at the Hospital Universitario de Canarias during June, July, and August 2024.
Materials and Methods
A descriptive observational study was conducted on a sample of 138 patients with obesity who underwent bariatric surgery and were evaluated by the Endocrinology and Nutrition Department at the Hospital Universitario de Canarias between June and August 2024. The variables analyzed included sex, weight one year after surgery, maximum body mass index (BMI), comorbidities such as hypertension (HTN), type 2 diabetes mellitus (T2DM), obstructive sleep apnea syndrome (OSAS), percentage of total weight loss, type of surgery performed, and remission of comorbidities.
Results
A total of 138 patients were studied, of whom 111 (80.4%) were women and 27 (19.6%) were men. The median maximum weight was 133 kg, with a mean maximum BMI of 49.89 kg/m^2. Among the comorbidities, 51.4% had hypertension, 66.7% had T2DM, and 17.4% had OSAS. The most commonly performed surgery was gastric bypass (71%), followed by sleeve gastrectomy (18.8%) and Scopinaro procedure (5.1%), while newer techniques such as SADI-S (2.9%) were less frequently used. A total weight loss of 36.88% was observed one year after surgery. Regarding T2DM remission, 26.1% of patients achieved

full remission, 65.2% showed improvement, and 8% had no changes, with an 18% reduction in HbA1c levels compared to baseline values.
Conclusions
Bariatric surgery remains a therapeutic option for patients with severe obesity who are unable to achieve weight reduction through lifestyle modifications and/or pharmacological treatment. The significant weight loss observed is directly associated with improvement in comorbidities and plays a crucial role in preventing future diseases.

Impact of respiratory function (FEV_1) on disease progression and mortality in patients with als: association with bioelectrical and biochemical parameters

Cristian Jesús Lucena Morales[1], María González Pacheco[1], Cayo Javier García Polo[2], María Alarcón-Manoja[3] & Francisco Javier Vílchez López[1]
[1]Hospital Universitario Puerta del Mar, Endocrinology and Nutrition Department, Cádiz, Spain; [2]Hospital Universitario Puerta del Mar, Pulmonology Department, Cádiz, Spain; [3]Hospital Universitario Puerta del Mar, Physical Medicine and Rehabilitation Department, Cádiz, Spain

Introduction
Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease that affects functional, nutritional, and respiratory status. The assessment of respiratory parameters such as forced expiratory volume in one second (FEV_1), bioelectrical, and biochemical markers allows for determining their impact on disease progression and mortality.
Objectives
In a cohort of patients with autoimmune lateral sclerosis: To analyze the relationship between respiratory function parameters (FEV_1) and bioelectrical, biochemical, and clinical indicators. To assess the association between respiratory function and mortality.
Materials and Methods
A prospective cohort study was conducted in patients attending the multidisciplinary ALS clinic at Hospital Puerta del Mar (Cádiz). Baseline respiratory function tests and morphofunctional assessments were performed. Mortality was evaluated after a mean follow-up of 18 months.
Results
The cohort included 22 patients, 52.6% women, with a median age of 65 years and a mean weight of 64.7 kg (BMI 23.7). At disease onset, 68.1% presented spinal symptoms, and 72.7% had bulbar involvement at baseline assessment. The predominant disease stages were: stage II (45%) and stage III (27.2%). The median ALSFRS-R score was 35, indicating moderate progression. Dysphagia was present in 59% of patients, and 54% had nutritional risk or malnutrition (VSG B or C). After 18 months of follow-up, 31.8% of patients had died. Twelve patients (54.5%) had $FEV_1 < 80\%$, which was associated with more advanced disease stages III-IV (OR: 24.8 [1.17–52.6]; $P = 0.006$), moderate-to-severe ALSFRS-R scores (OR: 8.17 [1.03–64.9]; $P = 0.037$), and higher mortality (OR: 9 [0.84–94.9]; $P = 0.045$). FEV_1 showed a positive correlation with bioelectrical impedance vector analysis (BIVA) parameters, including phase angle (PhA) ($r = 0.56$; $P = 0.008$) and body cell mass (BCM) ($r = 0.47$; $P = 0.033$), and a negative correlation with C-reactive protein (CRP) levels ($R = -0.754$; $P = 0.002$).
Conclusion
FEV_1 correlates with biochemical and bioelectrical parameters, and values below 80% are associated with advanced ALS stages, greater disease severity, and increased mortality. Baseline FEV_1 assessment, combined with morphofunctional evaluation, may help identify patients at higher risk of poor disease progression, guiding the intensification of multidisciplinary treatment and closer monitoring.

Understanding 'controlled obesity': perspectives of people with obesity on a new classification

Cesar Luiz Boguszewski[1], Bruno Halpern[2], Simone van de Sande-Lee[3], Maria de Melo[4], Rodrigo Lamounier[5], Cintia Cercato[4], Paulo Miranda[6], Rodrigo O. Moreira[7], Mario Carra[8] & Marcio Mancini[4]
[1]Endocrine Division (SEMPR), Federal University of Parana, Department of Internal Medicine, Curitiba, Brazil; [2]Obesity Center, Nove de Julho Hospital, Sao Paulo, Brazil; [3]Federal University of Santa Catarina (UFSC), Department of Internal Medicine, Florianopolis, Brazil; [4]Obesity Unit, Hospital das Clínicas, University of Sao Paulo, Department of Endocrinology, Sao Paulo, Brazil; [5]Federal University of Minas Gerais (UFMG), Belo Horizonte, Brazil; [6]Endocrinology Departament at Mater Dei Health System and Santa Casa Hospital, Belo Horizonte, Brazil; [7]Faculdade de Medicina do Centro Universitário Presidente Antônio Carlos (FAME/UNIPAC), Faculdade de Medicina de Valença, Centro Universitário de Valença (UNIFAA), Juiz de Fora, Brazil; [8]Hospital das Clínicas, University of Sao Paulo, Department of Endocrinology, Sao Paulo, Brazil

The Brazilian Association for the Study of Obesity (ABESO) and the Brazilian Society of Endocrinology and Metabolism (SBEM) have recently proposed a new classification of obesity based on the maximum weight attained in an individual's lifetime, as an additional tool to enhance understanding of the disease and facilitate discussions about treatment. In this classification, people with obesity (PwO) who lose a certain percentage of their weight are categorized as having "reduced" or "controlled" obesity. While the classification aims to improve patient care, there is limited data on PwO perceptions. To explore this, a cross-sectional online survey was conducted with 500 PwO, including an explanation and clinical case illustrating the new classification. The survey revealed that 94% of participants were certain or almost certain of their maximum weight, however 64% of them had never been asked about it by a healthcare professional (HCP). 65% of PwO believe that reaching a normal body mass index is necessary for improving their health and quality of life, despite evidence indicating that modest weight loss can enhance health outcomes. After reading about the new classification, 82% found it useful for changing perceptions about obesity treatment; 66% felt it would encourage them to seek treatment; 63% believed it would help with treatment maintenance; and 74% indicated they would feel better achieving "controlled obesity," even if the weight loss fell short of their goals. The majority agreed that the classification could help establish realistic goals (77%), reduce biases from HCPs towards PwO (68%) and make HCPs less strict with patients about weight loss (64%). For 74% of PwO, HCPs should adopt the new classification in treating obesity. Overall, PwO perceived the classification as beneficial for encouraging treatment and reducing stigma.

Relationship of iodine concentration with inflammatory and anthropometric characteristics and body composition in young adults

Ivan Dusper[1], Ivan Lekić[1,2], Željko Debeljak[3,4], Ines Banjari[5] & Tatjana Bačun[1,6,7]
[1]Faculty of Medicine Osijek, Department of Internal medicine, Osijek, Croatia; [2]Health center Zagreb - Centar, Department of Internal medicine, Zagreb, Croatia; [3]Faculty of Medicine Osijek, Department of pharmacology, Osijek, Croatia; [4]University hospital center Osijek, Clinical Institute for Laboratory Diagnostics, Osijek, Croatia; [5]Faculty of Food Technology Osijek, Osijek, Croatia; [6]University hospital center Osijek, Department of internal medicine, Osijek, Croatia; [7]Faculty of dental medicine and health, Osijek, Croatia

Iodine is a mineral categorized as a trace element. The majority of iodine in the body is located in the thyroid gland. Its primary function in the human body is the synthesis of hormones and the preservation of healthy thyroid activity. Iodine is crucial for the control of the immune system. It functions as an antioxidant, prooxidant, and possesses anti-inflammatory properties by modulating the release of cytokines and other inflammatory mediators. Iodine is mostly absorbed by the body via dietary sources, particularly iodized salt. The research aimed to investigate the dietary iodine intake in young adults, assess urinary iodine concentration in this demographic, explore the correlation between iodine concentration and inflammatory characteristics, analyze the relationship between iodine concentration and body composition, and evaluate the association between iodine concentration and anthropometric characteristics. The investigation involved 70 young adults aged 19 to 24, comprising 35 men and 35 women. Iodine metabolism disorders and confirmed thyroid diseases were exclusion criteria. Inflammatory and anthropometric parameters, body composition, urinary iodine concentration, and dietary iodine intake were examined. The median iodine concentration in the subjects' urine is 120.77 μg/l,while the median dietary iodine intake is 624.66 μg. The median body mass index is 23.72 kg/m^2. The

median body composition consists of 32.6% muscular tissue and 27.4% fat tissue. The median waist diameter is 75.5 cm, and the upper arm circumference is 27.8 cm. The median neutrophil-to-lymphocyte ratio is 1.5. No significant association between iodine levels in urine and any observed data was detected. The participants in this study exhibit an excessive dietary iodine intake and a urinary iodine concentration indicative of a population with adequate intake. No substantial correlation was seen between urinary iodine content and inflammatory, anthropometric, or body composition variables.

Key Words
iodine, inflammation, anthropometry, body composition.

GLP-1 receptor agonists and management of diabetes mellitus 2 and obesity in multiple sclerosis

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Xenia Poimenidi[1] & Panagiotis Athanassiou[3]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Diabetes and Metabolism, Athens, Greece; [2]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [3]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Multiple sclerosis is a demyelinating disorder of the central nervous system of autoimmune etiology and pathophysiology. The disorder is managed by the administration of immunomodulating agents. It may be accompanied by disability. As multiple sclerosis impairs mobility, obesity may accompany the disease. Additionally, diabetes mellitus type 2 may emerge. The aim was to describe a cohort of patients with multiple sclerosis, obesity and diabetes mellitus type 2 who were managed by the administration of GLP-1 receptor agonists. A cohort of 5 patients (4 female and 1 male), aged 35-55 years, is described who were followed up for multiple sclerosis. Patients were obese, BMI 31-39. Additionally, the presence of diabetes mellitus type 2 was diagnosed in 3 of the patients. GLP-1 receptor agonists were administered to this group of patients once weekly. Weight loss was noted after 6 months in this group of patients, weight loss ranging from 1.2 to 6.7 kg. GLP-1 receptor agonist administration was continued. No adverse effects were noted, apart from nausea in one of the patients. Multiple sclerosis is an autoimmune disorder characterized by demyelination. The disease causes mobility limitation and may be accompanied by obesity. Appropriate and effective obesity treatment is crucial in this group of patients as it may facilitate mobility and may prevent disability deterioration. The administration of GLP-1 receptor agonists is a proper treatment modality for this patient group as it seems not to be accompanied by severe adverse effects. In addition, it induces weight loss and acts therapeutically as an antidiabetic agent.

The relationship between insulin resistance, BMI, free testosterone and estradiol levels in male adults and adolescents

Maia Kuparashvili[1], Anzhelika Kardava[1], Eka Kakhidze[1] & Shota Janjgava[1]
[1]National Institute of Endocrinology, Tbilisi, Georgia

Introduction
This abstract explores the complex relationship between IR, BMI, free testosterone and estradiol levels in male adults and adolescents, highlighting the bidirectional influences that exacerbate metabolic and hormonal dis-regulation. Insulin resistance is linked to low free testosterone levels due to increased inflammation, weight gain (especially visceral fat) and impaired function of the hypothalamic-pituitary-gonadal axis. Visceral fat leads to more aromatase activity, converting testosterone into estradiol, which lowers testosterone levels further. Chronic hyperinsulinemia suppresses luteinizing hormone (LH), reducing the production of testosterone in the testes.

Objectives
The aim of this study was to analyze the association between Insulin resistance, BMI, Free testosterone and estradiol levels in male adults and adolescents.
Material and Methods
Cross-sectional study of 26 male patients from 13 to 44 years Including criteria were. Insulin resistance >2.27 and BMI >25 kg/m^2 Patients were divided into two age groups: A). 13-18 years (12 patients) and B). 19-44 years (14 patients) Free Testosterone deficiency was defined as levels $<$ 15 pg/ml in adults and $<$ 12.3 pg/ml in adolescents or excess estradiol levels more then 43 pg/ml in adults and >23 pg/ml in adolescents. In group A the studied population had a mean age of 15, mean HOMA -IR of 5.07, mean BMI - 33.2 In group B the studied population had a mean age of 30.5 and mean HOMA -IR of 6.4,. mean BMI- 35.
Results
Free Testosterone deficiency prevalence was 35.7 % in adults and 16.7 % in adolescents, while high estradiol prevalence were respectively 50 %(adults) and 25 %(adolescents) in groups, BMI values were 33. $\pm$10.5 (A) and 35 $\pm$10.5(B).
Conclusions
Our small study suggests a interplay between insulin resistance, low testosterone and high estradiol levels. The findings indicate that hormonal imbalances may contribute to worsening metabolic dysfunction, highlighting the importance of addressing both insulin sensitivity and hormone levels in treatment strategies. Further large-scale studies are needed to confirm these results and develop effective therapeutic approaches for mitigating associated health risks.

Home parenteral nutrition: experience in a tertiary hospital

Ana María Moyano-Sánchez[1], Concepción Muñoz Jiménez[1], Ángel Rebollo Román[1], María Ángeles Gálvez Moreno[1] & María José Molina Puerta[1]
[1]UGC Endocrinología y Nutrición. Hospital Universitario Reina Sofía, Department of Endocrinology and nutrition, Córdoba, Spain.

Introduction
Home parenteral nutrition (HPN) is the nutrition access of choice in patients with documented intestinal failure and inability to receive enteral nutrition exclusively.
Material and Objective
Retrospective descriptive study of patients who received HPN during 2023. Demographic variables related to HPN administration and nutritional status were analysed. The objective was to analyse the experience in the use of HPN and possible complications arising from the infusion in the Hospital Reina Sofia of Cordoba.
Results
11 patients. 9/11 women. Median age 61 years (30-87). Median follow-up time with HPN was 34 months (SDS 26.7). 8 patients with indication for HPN due to short bowel syndrome (SBS), 2 due to intestinal fistula, 1 due to extensive intestinal mucosal disease. The cause of SBS was mesenteric ischaemia (1), Crohn's disease (2), surgical complications (3), intestinal volvulopathy (1), adhesive syndrome (1). 72.7% (8) had an ostomy. Initially, 9/11 patients had PICC and 2/11 had Hickman as a central access route. At the end of follow-up, 100% of patients had PICC. According to the severity classification of chronic intestinal failure in adults: 3 FE1, 1 FE2, 3 PN1, 4 PN2. Mean kcal provided by HPN 1264 $\pm$ 155Kcal. 1 patient receiving Teduglutide treatment for 13 months. 4/11 patients had infectious catheter-related complications. 4/11 patients had catheter-related mechanical complications, mostly associated with catheter obstruction. 2/11 patients had their HPN withdrawn after 43 months (mean) of treatment, due to cure or improvement of their disease and nutritional parameters. 1 patient died due to catheter-associated complications. Weight prior to initiation of HPN 49.8 $\pm$ 11.4 kg, weight at last HPN follow-up 58.24 $\pm$ 13.6 kg [t -2.187, $P = 0.071$]. BMI prior to initiation of HPN 19.8 $\pm$ 4.76 kg/m^2. BMI at last HPN visit 24.6 $\pm$ 7.8 kg/m^2 [t -2.01, $P = 0.071$]. There is a trend towards improvement in albumin, pre-albumin, transferrin, total cholesterol, triglycerides, lymphocytes and haemoglobin after HPN, although the differences are not statistically significant.
Conclusions
The age and indication for HPN in our series is similar to the literature. There was an improvement in the weight and BMI of the patients after HPN and we did not find statistically significant differences in the improvement of nutritional parameters, although there was a trend towards improvement.

Clinical and biological aspects of malnutrition in adults

Dorra Ben Salem[1], Emna Bornaz[2], Sana Khamassi[2], Haifa Abdesselem[2], Kamilia Ounaissa[2], Rim Yahyaoui[2], Asma Ben Brahim[2], Saida Boumefteh[2] & Chiraz Amrouche[2]
[1]National Institute of Nutrition and Food Technology, Department Of Nutritional Diseases D, Tunis, Tunisia; [2]National Institute of Nutrition and Food Technology, Department of Nutritional Diseases D, Tunis, Tunisia

Introduction
Malnutrition is a common and insidious problem that often goes underdiagnosed. The aim of our study was to analyze the clinical and biological profiles of malnourished patients.
Materials and Methods
A cross-sectional study was conducted, including 35 patients followed for underweight in the outpatient department of the national institute of Nutrition. The following phenotypic criteria were collected: BMI, muscle strength (MS), and weight loss (WL).
Results
The mean age was 35.14 $\pm$ 15.95 years, with a predominance of females (82.9%). The mean BMI was 17.51 $\pm$ 4.3 kg/m^2. The average muscle strength (MS) and weight loss (WL) were 23.27 $\pm$ 10.1 kg and 15.83 $\pm$ 9.63%, respectively. The prevalence of malnutrition was 65.71%, according to the HAS recommendations, which include at least one phenotypic criterion and one etiological criterion. Severe malnutrition was observed in 56.52% of cases. The mean levels of albumin, hemoglobin, calcium, and magnesium were 41.73 $\pm$ 4.7 g/L; 11.98 $\pm$ 1.88 g/dl; 2.35 $\pm$ 0.11 mmol/l,and 0.8 $\pm$ 0.07 mmol/l,respectively. Hypoalbuminemia, anemia, hypocalcemia, and hypomagnesemia were noted in 9.1%, 45.71%, 5.7%, and 20% of cases, respectively. Malnutrition was associated with weight loss ($P = 0.001$). Anemia was linked to a reduction in muscle strength ($P = 0.03$). No correlations were found between magnesium levels and the different anthropometric parameters, nor between calcium levels and the parameters.
Conclusion
Malnutrition often presents subtly, underscoring the importance of early detection and heightened awareness among healthcare providers..

Cardiovascular risk profile and achievement of therapeutic targets in patients with diabetes mellitus

Yesmine Elloumi[1], Ekram Hajji[1], Zeineb Rekaya[1], Bilel Ben Amor[1], Hanene Sayadi[1] & Ines Khochtali[1]
[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Introduction
Type 2 Diabetes mellitus (T2DM) is a chronic condition associated with increased cardiovascular risk, which remains a significant cause of morbidity and mortality. Despite advances in diabetes management, many patients fail to meet therapeutic. The complexity of managing cardiovascular risk factors alongside glycemic control poses challenges in clinical practice.
Methods and Aims
A descriptive cross-sectional study was conducted on 80 patients with T2DM who had been attending outpatient consultations in the endocrinology department of a Tunisian medical center for at least six months. The objective was to evaluate major cardiovascular risk factors, stratify patients according to the 2023 ESC risk score, and assess treatment adherence along with the attainment of therapeutic goals.
Results
The average age of the patients was 57.9 years, with a female predominance (65%). Poor diabetes control was mainly attributed to inadequate therapeutic adherence in 33.8% of cases. Arterial hypertension was present in 46 patients. 26.3% of patients were not meeting therapeutic targets, Dyslipidemia was observed in 67.5% of patients. 27.5% of patients did not reach their LDL cholesterol targets. Obesity was present in 45% of cases, and 10% of patients had not quit smoking. The cardiovascular risk was moderate in 6.3% of patients, high in 61.3%, and very high in 32.5%.
Conclusion
This study underscores the importance of better strategies to achieve cardiovascular risk targets in diabetic patients to prevent complications and improve long-term health outcomes.

Introduction
NASH is an increasingly relevant finding in the pediatric population affected by obesity. In adults, the evolution of this steatosis towards fibrosis and correlation with metabolic syndrome is increasingly significant. The existence of a rapid and validated in-office screening tool would be very useful.
Main objective
To evaluate whether the measurement of intraperitoneal fat measured through nutritional ultrasound allows for the diagnosis of non-fatty hepatic steatosis or metabolic risk in overweight/obese patients. Establish if there is any type of correlation between abdominal fat measurements obtained by nutritional ultrasound and those obtained in routine clinical practice of these patients using liver ULTRASOUND if this is performed within routine clinical practice.
Material and Methods
Patients who attend of Endocrinology due to overweight. BMI >2 SDS. MINDRAY Z50 ULTRASOUNDGRAPH. (**Hamagawa technique) through an** abdominal adipose ultrasound study (Superficial subepidermal fat – stored, deep and intraperitoneal energy-risk in adults for NASH). Comparison with ECO performed by expert radiologists.
Results
Study on 150 patients with deep ECHO by an expert pediatric radiologist and nutritional ECHO. NASH 90/150 (60%). Distribution mild 72/150 (48%), moderate 14/150 (9%) and severe 3/150 (1.7%). A Mann-Whitney U test was performed on 150 patients. The results showed that the cut-off point that presents confirm a positive correlation between NASH YES/NO would be an average of 0.82 cm CI[0.70-0.94] 95% using Mann-Whitney U. Children who lost weight (fat mass by impedanciometer TANITA) after unless 12 mouths has measures of pre-peritoneal fat less than children who not.
Conclusion
There is a significant number of pediatric cases with NASH in the obese population. The use of rapid nutritional ECO (preperitoneal fat) is related by a linear and positive correlation with the presence of NASH studied by traditional ECO in expert hands.

Overweight and obesity among healthcare professionals in tunisia: prevalence and associated factors

Maryam Naifar[1], Houda Ben Ayed[2], Faten Hadjkacem[2], Hanen Maamri[2], Sourour Yaich[2] & Jamel Dammak[2]
[1]Institut National de Nutrition, Tunis, Tunisia; [2]Hedi Chaker Sfax, Tunisia

Introduction
Obesity has become a major public health problem because of its potential impact on health and its alarming increase worldwide. The objectives were to estimate the prevalence of overweight and obesity among healthcare professionals (HCPs) and to examine their associated factors.
Methods
We conducted a cross-sectional study during the period August2022-November 2022 among HCPs in the two-university hospital Habib Bourguiba and Hedi Chaker of Sfax governorate, Southern Tunisia. To screen for EDs, we opted for the validated French version of the Eating Attitude Test (EAT-26).
Results
The median age was 30 years (Interquartile range (IQR) = [26-40]). In this study, 253 HCPs were aged 35 years or more (68.4%). Females represented 74.6% of

participants ($n = 276$). The mean Body Mass Index (BMI) was 24.79 ± 3.74 kg/m^2. The prevalence of overweight was 40.8%. Among the participants, 24.6% were at high risk of developing eating disorders. In multivariate analysis, factors independently associated with the prevalence of overweight in HCP were a number of working years $\geq$ 10 years (adjusted odds ratio (AOR) $= 5.7$; $P < 0.001$), large weight variation $\geq$25Kg during adulthood (AO $r = 3.5$; $P = 0.038$), distortion in body image perception (AO $r = 2.2$; $P = 0.01$), dissatisfaction with the current weight (AO $r = 5.3$; $P < 0.0001$) and high risk of developing eating disorders (ED) according to the EAT-26 score (AO$r = 1.8$; $P = 0.041$).

Conclusions

The alarming figures for overweight have been illustrated, justifying the introduction of preventive measures in the workplace in order to avoid the deleterious consequences.

Elevated liver enzymes in a patient with obesity and sleep-related eating disorder during semaglutide therapy

Katie Boron[1] & Disha Narang[1]

[1]Endeavor Health, Skokie, United States

Background

Semaglutide, a GLP-1 receptor agonist, is widely used for weight management and has been associated with improvements in liver enzymes and hepatic steatosis. Reports of hepatotoxicity are rare.[1].

Case Presentation

A 42-year-old female with a history of obstructive sleep apnea and sleep-related eating disorder presented for weight management. She had been on semaglutide for two years, achieving a 40-pound weight loss. In December 2023, she contracted COVID-19, followed by multiple infections treated with consecutive courses of antibiotics. In April 2024, she reported fatigue and malaise; laboratory tests revealed elevated liver enzymes (AST 222 U/l,ALT 333 U/L). Semaglutide and amoxicillin were discontinued, but liver enzymes further increased (AST 600 U/l,ALT 342 U/l)before gradually declining. Subsequent use of Bactrim led to a transient rise in liver enzymes.

Discussion

The temporal association between semaglutide discontinuation and the rise in liver enzymes suggests a potential link. However, the concurrent use of multiple antibiotics and recent infections complicate the attribution of hepatotoxicity solely to semaglutide. Notably, semaglutide has been associated with liver enzyme reductions in patients with obesity and type 2 diabetes, and recent studies have indicated its potential benefits in improving liver fibrosis in patients with metabolic dysfunction-associated steatohepatitis.[2].

Conclusion

This case underscores the importance of monitoring liver function in patients receiving semaglutide, especially those with complex medical histories and concurrent medication use. Further research is warranted to elucidate the hepatic effects of semaglutide and its safety profile in patients with predisposing factors for liver dysfunction.

Linkage between obesity and bone metabolism

Zulaykho Shamansurova[1,2], Saidolim Maxmudov[3] & Rakhim Zakirov[1]

[1]Central Asian University, Endocrinology, School of Medicine, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan; [3]Toronto Metropolitan University, Biomedical Engineering, Toronto, Canada

Introduction

Obesity affects bone metabolism through various mechanisms. Adipocytes and osteoblasts originate from a common progenitor, mesenchymal stem cells. Obesity itself by promoting adipocytes differentiation can lead to osteoporosis. Whereas chronic inflammation also shown associated with obesity and can also increase osteoclast activity, resulting in bone resorption. We tried to identify more common factors for development of obesity and osteoporosis.

Material and Methods

We gathered available data from internet Published data from the past two decades from sources such as MEDLINE, PubMed, Scopus, and Web of Science were systematically analyzed to evaluate to common factors development of obesity and osteoporosis.

Results

Literature search showed range of factors. Major factor is hormonal Influences. Adipose tissue is an active endocrine organ that secretes various hormones and cytokines, increasing fat mass leads to their higher production and can significantly affects bone metabolism. The interplay between energy metabolism and bone health is complex, with bone cells actively participating in metabolic regulation. Osteocalcin: This bone-derived hormone influences glucose metabolism and fat mass. Dysregulation of osteocalcin in obesity can affect both metabolic health and bone quality. Bone Marrow Adiposity: Increased adiposity within the bone marrow can interfere with bone remodeling by altering the balance between osteoblast and adipocyte differentiation. Dietary factors, high fat intake can interfere with calcium absorption, affecting bone health. Weight loss interventions, including bariatric surgery, have been shown to have mixed effects on bone health, sometimes leading to decreased BMD and increased fracture risk. Mechanical factor Increased body weight in obese individuals leads to greater mechanical loading on the skeleton, which stimulates bone formation through mechanotransduction. This process involves the conversion of mechanical stimuli into biochemical signals that promote osteoblast activity and bone mineralization. However, the distribution of this loading and its effects on different bone sites can vary, potentially leading to uneven bone strength. TNF-α and IL-6: These cytokines increase osteoclast activity, leading to enhanced bone resorption. The chronic inflammatory state associated with obesity can thus predispose individuals to bone loss and increased fracture risk despite higher bone mineral density.

Conclusion

The relationship between bone and adipocytes is multifaceted, involving shared origins, hormonal influences, mechanical loading, cell signaling, and metabolic factors. Understanding these connections is crucial for developing strategies to improve bone health and manage obesity-related bone issues.

A case report of Familial hypercholesterolemia

Fatima Zahra El Jaafari[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]

[1]Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakech, Morocco

Introduction

Familial hypercholesterolemia (FH) is a prevalent autosomal co-dominant disorder within the group of primary dyslipidemias, characterized by elevated plasma cholesterol levels, particularly low-density lipoprotein cholesterol (LDL-C), which is significantly increased. FH results in early-onset and progressive cardiovascular disease (CVD), often becoming clinically evident during childhood and adolescence. As a result, it is crucial to tightly regulate cholesterol metabolism. Early diagnosis and prompt, intensive treatment are essential for managing the condition.

Patients et Methods

This case report outlines the situation of a patient diagnosed with familial hypercholesterolemia, who is currently under follow-up in the Endocrinology, Diabetology and Metabolic diseases department of the Mohamed VI university hospital center in Marrakech.

Results

A 17-year-old patient with no significant medical history presented for screening for familial hypercholesterolemia (FH). Her father and sister were already being treated for FH in our department. Born to non-consanguineous parents, her

developmental milestones were reported as normal. There is no history of chest pain, shortness of breath, hypertension, diabetes, hypothyroidism, or other chronic conditions, and she is not taking any medications. On clinical examination, aside from moderate obesity, particularly in the abdominal area, she exhibited a buffalo hump and acanthosis nigricans. Her lipid profile showed a total cholesterol level of 282 mg/dl, LDL at 202 mg/dl, while triglycerides and HDL cholesterol were within normal ranges. Further investigations into the underlying cause and potential cardiovascular complications were normal. The patient was advised to follow a low-cholesterol diet, prescribed Rosuvastatin 10 mg, and scheduled for follow-up.
Conclusion
Diagnosing FH is crucial not only for the patient's prognosis but also for the family members who might inherit the condition. Early identification and prompt treatment can extend the lives of these patients and help prevent cardiovascular complications.
Keywords
Familial hypercholesterolemia, CVD, LDL cholesterol.

Impact of PCSK9 inhibitors in the management of homozygous familial hypercholesterolemia: a case report
Mariam Mabrouk[1], Chedia Zouaoui[1], Sahar Abidi[1], Bchir Najla[1], Annam Benchhida[1], Dorra Dorraelguiche[1] & Haroun Ouertani[1]
[1]Military Hospital of Tunis, Endocrinology Department, Tunis, Tunisia

Introduction
Familial hypercholesterolemia (FH) is a genetic disorder primarily caused by mutations in the gene encoding the LDL receptor (90%), apolipoprotein B (5%), or PCSK9 (1%), leading to elevated LDL cholesterol levels and a significantly increased risk of premature atherosclerotic cardiovascular disease. We report the case of a 24-year-old female with homozygous FH managed with PCSK9 inhibitors.
Case Report
The patient, a 24-year-old woman, had been followed since the age of 4 for homozygous FH. Her brother underwent coronary artery bypass grafting at the age of 27 for severe coronary artery disease. She presented with ischemic heart disease and severe aortic insufficiency. Surgical interventions, including coronary artery bypass and valve replacement, were deferred due to poorly controlled hypercholesterolemia despite treatment with rosuvastatin 20 mg/day and ezetimibe 10 mg/day. Physical examination revealed tendon xanthomas on the hands, elbows, and knees. Body mass index (BMI) was 31.17 kg/m^2, and blood pressure was 130/70 mmHg. Laboratory findings included total cholesterol (TC) at 9.28 g/l,LDL cholesterol (LDLc) at 8.03 g/l,and triglycerides (TG) at 1.1 g/L. Rosuvastatin was increased to 40 mg/day, and acetylsalicylic acid 100 mg/day was added. Cholestyramine was not tolerated. After 3 months of treatment, TC was 8.12 g/l,and LDLc remained at 8 g/L. Consequently, PCSK9 inhibitors were initiated at the dose of 420 mg subcutaneous injections monthly. This resulted in a 36% reduction in TC and a 41% reduction in LDLc.
Conclusion
This case highlights the complexity of managing homozygous familial hypercholesterolemia and the crucial role of PCSK9 inhibitors in improving lipid profiles. This treatment can reduce atherogenic risk and improve life expectancy in these high-risk young patients.

Assessment of physical activity levels among paramedical staff: a cross-sectional study
Mariem Ayedi[1], Khouloud Boujelben[1], Dhoha Ben Salah[1], Mohamed Khairi Arous[1], Yassmine Abdelkafi[1], Mouna Mnif[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]University of Sfax, Faculty of Medicine of Sfax, Hedi Chaker University Hospital, Endocrinology Diabetology Department, Sfax, Tunisia

Introduction
The prevention of cardiovascular diseases remains a crucial challenge in healthcare, as they represent one of the leading causes of death worldwide. Physical inactivity exposes individuals to a significant risk of mortality due to cardiovascular diseases and all-cause mortality, representing a major concern for healthcare professionals.
Objective
To assess the level of physical activity among paramedical staff at the Intermediate Health Center of Sfax, Tunisia.
Patients and Methods
This was a descriptive cross-sectional study conducted among 41 paramedical staff members at the Intermediate Health Center of Sfax. We assessed their perception of physical activity in the workplace using a version of the BAECKE questionnaire adapted to the Tunisian dialect.
Results
The mean age of participants was 41 years (27–59 years) with a female predominance (75.7%). The majority (87.2%) had over 5 years of professional experience. The mean weight was 75.5 kg (59–110 kg), with a mean BMI of 29.6 kg/m^2. An android fat distribution was observed in 54.2% of participants. Twelve percent of respondents were obese. Among the participants, 78.6% spent most of their time seated vs 21.4% standing. Most respondents (85.7%) frequently felt fatigued at work, and 78.5% perceived their job as moderately or minimally physically demanding compared to others of the same age. The assessment of the Work Physical Activity Index (WPAI) identified three categories: high WPAI (25%), low WPAI (35%), and moderate WPAI (40%).
Conclusion
Promoting physical activity in the workplace improves cardiovascular health, and reducing desk hours may be associated with a decrease in adiposity, overweight, and obesity.

Personalized diagnosis of obesity types using the typeobese bot
Maksym Zubenko[1], Nataliia Pashkovska[1] & Iryna Tsaryk[1]
[1]Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
Obesity results from the interaction of genetic factors with numerous environmental factors. The comprehension of the molecular mechanisms of obesity progressed enormously in the last years thanks to the development of faster and more precise genetic screening tools applied in cohort studies or in examinations with focus on subjects and their families. In particular, whole-exome sequencing showed its power to identify new syndromes associated with obesity or new forms of obesity due to a single naturally occurring dysfunctional gene (i.e. monogenic obesity). In particular, obesity is a global medical and social issue, leading to complications such as cardiovascular diseases, type 2 diabetes mellitus, and oncological pathologies. One of the main challenges is the accurate diagnosis of obesity type, as different forms (endocrine, hypothalamic, alimentary, genetic, etc.) require specific treatment approaches. The implementation of innovative technologies, such as chatbots, can significantly improve the quality of diagnosis and treatment.
The aim of the study
To improve diagnosis of obesity types using a TypeObese Telegram bot to increase patient-centered treatment and improve the efficiency of medical care.
Materials and Methods
Based on literature analysis, international guidelines, and clinical observations, an algorithm for the differential diagnosis of obesity types was developed. This algorithm was implemented in the form of the TypeObese Telegram bot, which applies an individualized approach to each patient. The bot collects clinical data, analyzes examination results, and provides recommendations for additional diagnostics.
Results
The TypeObese Telegram bot supports physicians of various specialties working with obese patients. Its functionality includes iystematic collection of information on body mass, lifestyle, medical history, and comorbidities, differentiation of endocrine, hypothalamic, and other types of obesity, recommendations for further examinations, such as hormone, leptin, and insulin level analyses. Testing of TypeObese demonstrated its usability in both primary and secondary healthcare settings, high accuracy in identifying obesity types, reduction of cognitive load on physicians, and increased awareness of rare obesity forms, such as hypothalamic or genetic obesity.
Conclusions
TypeObese is an effective tool for optimizing the diagnosis of obesity types. Its implementation enhances treatment individualization, improves healthcare efficiency, and helps prevent complications. The integration of similar solutions into clinical practice is recommended to improve obesity diagnosis and management.

Gut microbiota in obesity; mystic relation

Pinky Meena[1] & Maharshi Trivedi[2]
[1]All India Institute of Medical Sciences, Pediatrics, Rajkot, India; [2]GCRI, Ahmedabad, India

Obesity is a complex, multifactorial condition characterized by excessive adiposity, which results from an imbalance between energy intake and expenditure. Recent research has highlighted the critical role of gut microbiota in the pathogenesis of obesity. The human gut is home to trillions of microbes, including bacteria, fungi, and viruses, which influence host metabolism and immune function. Emerging evidence suggests that alterations in the gut microbiome composition are associated with obesity and metabolic disorders. The gut microbiota in obese individuals is often dysbiotic, with a reduction in microbial diversity and an increased ratio of Firmicutes to Bacteroidetes. This imbalance has been linked to increased energy harvest from the diet, as certain microbial species are capable of fermenting undigested carbohydrates into short-chain fatty acids (SCFAs), which can promote fat storage. Additionally, gut microbiota may influence adiposity through the modulation of hormones such as ghrelin, leptin, and insulin, which regulate appetite and metabolism. Furthermore, dysbiosis in obesity is associated with systemic low-grade inflammation, which plays a central role in the development of insulin resistance and metabolic syndrome. This inflammatory state is thought to be mediated by gut-derived endotoxins, such as lipopolysaccharides, which can translocate into the bloodstream, promoting inflammatory responses. Interventions targeting the gut microbiome, such as probiotic supplementation, prebiotic dietary fibres, and fecal microbiota transplantation, are under investigation as potential therapeutic strategies for obesity. While promising, these interventions require further validation in large-scale clinical trials. In conclusion, the gut microbiome plays a significant role in the pathophysiology of obesity, and understanding its intricate interactions with host metabolism may offer novel approaches to the prevention and treatment of this global health epidemic.

Endothelial function and diabetes complications in patients with T2DM after coronary stent placement

Gulshan Kalandarova[1], Zulaykho Shamansurova[2,3], Mohammed Abdul Haseeb[4], Durdona Kayumova[1] & Madina Yusupova[1]
[1]Republican Specialised Scientific Practical Medical Centre of Endocrinology, Tashkent, Uzbekistan; [2]Central Asian University, Endocrinology, School of Medicine, Tashkent, Uzbekistan; [3]Institute of Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan; [4]Kimyo International University In Tashkent (KIUT), Tashkent, Uzbekistan

Introduction
Cardiovascular disease (CVD) remains the leading cause of morbidity and mortality among patients with type 2 diabetes mellitus (Dm^2). Endothelial dysfunction, a hallmark of diabetes-related vascular complications, plays a central role in the pathophysiology of CVD. Last two decades due to cardiovascular intervention management improved CVD outcomes and early mortality cases were prevented among patients with Dm^2. We aimed to analyse data from literature how that improvement reflected in endothelial dysfunction especially in patients after stent placement.
Materials and Methods
Published data from the past two decades from sources such as MEDLINE, PubMed, Scopus, and Web of Science were systematically analyzed to evaluate the endothelial function in patients after stent placement.
Results
According to data from literature, as mechanisms of endothelial dysfunction in Dm^2 patients were considered inflammation, endothelial-mesenchymal transition, oxidative stress as well as cell death. In numerous studies reduced synthesis and accelerated breakdown of nitrogen monoxide was linked to endothelial dysfunction in diabetics with CVD. Furthermore, emerging evidence highlights the role of Asymmetric Dimethylarginine (ADMA), an endogenous inhibitor of endothelial nitric oxide synthase (eNOS), as a biomarker and risk factor for endothelial dysfunction. Elevated ADMA levels are associated with increased cardiovascular mortality in patients with coronary artery disease. Coronary stenting in diabetes individuals seen as an effective operation, exhibiting a high angiographic and clinical success rate comparable to that of non-diabetic patients. The significant developments in PCI devices (bare-metal stents and first- and second-generation drug-eluting stents), alongside technological innovations, clinical experiences, and supplementary pharmacotherapies, have substantially enhanced PCI results over time, especially in patients with diabetes mellitus complicated with coronary artery disease. However, in reviewed literature, T2DM patients had a higher prevalence of in-hospital myocardial infarction and an increased requirement for supplementary cardiac revascularization and need for thorough glycemic control after the operation. In terms of therapeutic targets in T2DM patients with CVD most of the research suggested metformin, DPP-4 inhibitors, GLP-1 receptor agonists, SGLT2 inhibitors, miRNA, and stem cells, which possess potential for clinical application.
Conclusion
This study addresses a critical gap in understanding the endothelial function and diabetes complications in T2DM patients after undergoing coronary stent placement. Its findings will contribute to better clinical management and reduced burden of diabetes-related complications.

Obesity as a chronic refractory to treatment disease which may be dealt with successfully

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Xenia Poimenidi[1] & Panagiotis Athanassiou[3]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Diabetes and Metabolism, Athens, Greece; [2]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [3]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Modern way of life is characterized by lack of physical activity and the abundance of food. This food abundance is due to the miracles of modern technology applied in farming which allows the production of enough food to sustain the increasing earth population. However, poverty still exists, leading to the necessity to consume food rich in carbohydrates and lipids. This modern way of life has led to the increasing incidence and prevalence of obesity. Obesity is characterized by increased morbidity and mortality which may be due to arterial hypertension, dyslipidemia and premature atherosclerosis and diabetes mellitus type 2. Numerous agents have recently emerged for the management of obesity with debatable results. The aim was to describe a cohort of patients with obesity followed up at a tertiary facility who were managed by multiple management plans and were led to successfully lose weight over a period of 5 years. A cohort of 30 patients with obesity is described. Patients presented with obesity and thyroid disorders and diabetes mellitus type 2 in 20 of the patients. They were managed by various treatment plans and various diets over a period of 5 years. In particular, triiodothyronine was administered to some patients if they had a coexisting thyroid disorder, metformin was administered to some patients if they had diabetes mellitus type 2 and GLP-1 receptor agonists were administered to some of the patients if they were refractory to treatment. A minority of the patients, 3 patients achieved weight loss with diet and a program of physical activity. A group of 23 patients were refractory to the administration of either triiodothyronine or metformin and a plan of diet and physical activity. This group of patients was administered GLP-1 receptor agonists and achieved weight loss 1.8-10.2 kg. Four patients were referred to surgeons for surgical treatment of obesity and returned for follow up with the administration of GLP-1 receptor agonists. One patient in the group who had surgical treatment developed a large abdominal abscess and had to have corrective surgery. Patients who had surgical treatment for obesity management achieved weight loss, however, they needed follow-up treatment with GLP-1 receptor agonists. Obesity is a chronic disease refractory to treatment. Recurrence is common. However, it appears that multimodal treatment with diet, a plan of physical activity and the use of multiple pharmaceutical agents including GLP-1 receptor agonists may lead to successful weight loss in the majority of patients.

Optic disc drusen: an exceptional manifestation of pseudohypoparathyroidism

Mohamed Khairi Arous[1], Faten Haj Kacem Akid[1], Sofien Affes[2], Kouloud Boujelben[1], Dhoha Ben Salah[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1], Amira Trigui[2] & Nabila Rekik Majdoub[1]

[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [2]Habib Bourguiba University Hospital, Department of Ophtalmology, Sfax, Tunisia

Introduction
Optic disc drusen (ODD) are acellular calcified deposits located in the optic nerve head. Although they are generally asymptomatic and rare (prevalence of 0.3% to 2.4%), they can be associated with chronic hypocalcemia. We report a rare case of pseudohypoparathyroidism associated with bilateral ODD.
Case Report
A 16-year-old adolescent was hospitalized for severe hypocalcemia (1.17 mmol/l)revealed by a generalized tonic-clonic seizure, associated with hyperphosphatemia (2.49 mmol/L). The medical history revealed asthenia, anorexia, and chronic paresthesia evolving over 2 years, as well as an acute episode of muscle contractures with respiratory distress. The patient exhibited normal growth, psychomotor development, and pubertal progression. The diagnosis of pseudohypoparathyroidism was established based on the association of chronic hypocalcemia, hyperphosphatemia, and an elevated PTH level (446 pg/ml). Type IB was considered the most plausible form due to the absence of dysmorphic features or other endocrine abnormalities. Ophthalmological examination revealed bilateral pseudo-papilledema, confirmed as ODD by OCT, with no associated cataracts. Brain imaging showed calcifications of the basal ganglia consistent with Fahr syndrome, strengthening the link between hypocalcemia and calcified deposits. Management included parenteral and oral calcium supplementation combined with active vitamin D. Clinical and biochemical improvements were observed under treatment.
Discussion and conclusion
ODD in the context of pseudohypoparathyroidism represent an exceptional manifestation, likely facilitated by chronic hypocalcemia. The classical ocular manifestation of chronic hypocalcemia is peripheral cataracts. An association between cataracts and optic nerve drusen has been reported in a patient with Di George syndrome. The underlying pathophysiological mechanism remains unclear but is hypothesized to involve dysregulated calcium metabolism, as observed in other hypocalcemic syndromes. This case highlights the importance of systematic ophthalmological evaluation in patients with severe chronic hypocalcemia. Although no treatment exists for ODD, periodic monitoring is crucial to prevent long-term complications.

The impact of 1-hour plasma glucose on the metabolic characteristics and pregnancy outcomes in polycystic ovary syndrome

Xiu Huang[1], Fan Yang[2], Hui Yu[2], Nan Lu[3], Lihua Wang[3], Lan Fang[4], Shen Qu[5], Hongwei Ji[6] & Manna Zhang[7]
[1]Department of Nuclear Medicine, Shanghai Tenth People's Hospital, School of Medicine, Tongji University, Shanghai, China; [2]Center for Reproductive Medicine, The First People's Hospital of Chenzhou, Hunan, China; [3]Department of Endocrinology and Metabolism, Shanghai Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [4]Tongji University Cancer Center, Shanghai Tenth People's Hospital, School of Medicine, Tongji University, Shanghai, China; [5]Department of Endocrinology and Metabolism, Shanghai Tenth People's Hospital, School of Medicine, Tongji University, Shanghai, China; [6]Tsinghua Medicine, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China; [7]Department of General Practice, Shanghai Tenth People's Hospital, School of Medicine, Tongji University, Shanghai, China

Purpose
To investigate the impact of 1-hour plasma glucose (1h-PG) on the metabolic characteristics and pregnancy outcomes in polycystic ovary syndrome (PCOS) patients.
Methods
A total of 1122 PCOS patients from Shanghai Tenth People's Hospital, Shanghai Renji Hospital, and Chenzhou First People's Hospital during 2019-2024 were recruited. Among them, 289 patients underwent assisted reproductive technology and 123 eventually delivered successfully. According to these patients' plasma glucoses, we classified the whole cohort into three groups: Group 1: fasting PG (FPG) $\leq$ 6.1 mmol/l,1h-PG $\leq$ 8.6 mmol/l,2-hour PG (2h-PG) $<$ 7.8 mmol/L; Group 2: FPG $\leq$ 6.1 mmol/l,8.6 mmol/L $<$ 1h-PG $<$ 11.6 mmol/l,2h-PG $<$ 7.8 mmol/L; Group 3: FPG $\leq$ 6.1 mmol/l,7.8 mmol/L $\leq$ 2h-PG $\leq$ 11.1 mmol/L. Geographical characteristics such as age, body mass index (BMI), blood pressure, waist-hip-ratio, PCOS classification; and clinical biomedical indicators, sex hormones and pregnancy outcomes were collected.
Results
For metabolic characteristics, when compared with Group 1, PCOS patients in Group 2 were more likely to have a higher incidence of hyperlipidemia, metabolic syndrome (MetS) and hyperuricemia, but were not significantly different from those of the Group 3. After adjustment for age, BMI and PCOS classification, the adjusted odds ratios (ORs) for incidence of hyperlipidemia, metabolic syndrome (MetS), and hyperuricemia in PCOS patients with Group 2 were 1.576 (1.121-2.216, $P = 0.009$), 1.804 (1.002-3.246, $P = 0.049$), 1.734 (1.224-2.457, $P = 0.002$), respectively. For pregnancy outcomes, PCOS patients in Group 2 were more likely to progress to gestational diabetes mellitus (GDM) than those of the Group 1, but were comparable to those of in Groups 3. After adjustment for age, BMI and PCOS classification, the adjusted OR for GDM in the Group 2 was 3.931 (1.122-13.777, $P = 0.032$).
Conclusions
Our study demonstrated that similar to 2h-PG, PCOS patients with elevated 1h-PG had a significantly higher risk of different metabolic disorders and GDM. Therefore, patients with PCOS should be emphasized the harmful effects of 1h-PG, which can be used for earlier screening and interventions in high-risk PCOS patients.

Continuous glucose monitoring in patients with cushing's syndrome, before and after surgical therapy

Laura Kligge Rodriguez[1], Lea Tschaidse[1], Ann-Christin Welp[1], Stephanie Zopp[1], Isabel Stüfchen[1], Hanna Nowotny[1], Elisabeth Nowak[1], Martin Reincke[1] & Nicole Reisch[1]
[1]Klinikum der Universität München, LMU, Medizinische Klinik und Poliklinik IV, munich, Germany

Background
Patients with endogenous Cushing's syndrome (CS) face an elevated cardiometabolic risk, which is linked to increased morbidity and mortality. This increased risk is partly driven by an impaired glucose metabolism, which is influenced by elevated cortisol levels and a disrupted circadian cortisol rhythm. The aim of this study was to improve the understanding of the glucose metabolism in patients with CS, utilizing continuous glucose monitoring (CGM) before and after surgical intervention.
Methods
This was a prospective, cross-sectional and longitudinal study. We included ten adult patients (9 female, 1 male) with CS (6 pituitary, 4 adrenal), and an HbA1c $<$ 7.0 %. The data collection with CGM was conducted before surgical intervention and 3 and 6 months postoperatively. At 3 months, all patients received a median hydrocortisone dose of 32.5 mg (IQR 15.0), which was reduced to 20.0 mg (IQR 10.0) at 6 months. At each time point continuously measured glucose concentrations, fasting glucose and insulin concentrations, HBA1c and BMI were compared.
Results
At baseline, patients had a median age of 36.7 years (26-50) and a median BMI of 33.2 kg/m^2 (23.8-51.7). Preliminary data indicate that the median (IQR) nocturnal glucose concentration was significantly higher at baseline (117.2mg/dl (26.55)) compared to three and six months post-surgery (99.53 mg/dl (23.63), $P = 0.022$; 100.77 mg/dl (10.78), $P = 0.022$). No significant differences were observed during the daytime. The median time (IQR) spent in the mild hyperglycemia range (140-180 mg/dl) per night (10pm to 6am) was significantly longer at baseline (13.70 % (20.65), 3 hours and 17 minutes), compared to three and six months post-surgery (4.71 % (9.76), 1 hour and 8 minutes, $P = 0.01$; 3.89 % (8.35), 56 minutes, $P = 0.044$). Fasting glucose and insulin concentrations, HbA1c or BMI did not change significantly.
Conclusion
These preliminary findings suggest that surgical therapy in patients with CS leads to significant improvements in nocturnal glucose control, with stabilization occurring within three to six months post-surgery. The results highlight the potential for CGM to offer valuable insights into glucose metabolism in CS, particularly during the night. Furthermore, CGM could contribute to the early detection of post-surgical relapse by identifying changes in glucose levels that may reflect a recurrence of the condition.

Bridging the gap: a comprehensive analysis of adolescent PCOS treatments and outcomes across decades

Noor Hamed[1], Ashraf Soliman[1], Carolin Beck[2], Nada Alaaraj[1], Shayma Ahmed[1], Fawzia Alyafei[1] & Aml Sabt[3]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Hamad Medical Corporation, Pediatric Endocrine and Diabetes, Doha, Qatar; [3]Sidra Medicine, Doha, Qatar

Background
Polycystic ovary syndrome (PCOS) is a prevalent endocrine disorder in adolescents, marked by menstrual irregularities, hyperandrogenism, and metabolic dysfunction. Early diagnosis and tailored treatments are essential to mitigate long-term risks such as infertility and diabetes. This review evaluates the effectiveness of lifestyle, pharmacological, and combination therapies in managing adolescent PCOS.
Objective
This study reviews treatment options and outcomes for adolescents with PCOS from 1990 to 2024, focusing on the efficacy of lifestyle interventions, pharmacological treatments, and combination therapies. Success rates, number of studies, and patient data were analysed for each treatment type.
Methods
Fifteen studies involving 1,062 adolescent patients were reviewed. Data were synthesized into three categories of therapy, with outcome success rates and patient improvements evaluated.
Results
• Lifestyle Modifications: Six studies, including 450 adolescents, demonstrated that diet and exercise significantly improved metabolic and reproductive outcomes, with 65%-80% success rates in reducing insulin resistance and improving ovulation. Weight reduction was particularly effective in obese patients, contributing to better glucose tolerance and reduced androgen levels. These foundational interventions are critical for long-term metabolic health.
• Pharmacological Treatments: Ten studies with 612 patients highlighted the efficacy of medications like metformin and oral contraceptives (OCs). Metformin showed success in normalizing glucose tolerance in 66.7% of cases and improving insulin sensitivity in 80%. OCs were effective in regulating menstrual cycles and reducing androgenic symptoms, with response rates between 60%-77.8%. Antiandrogens also showed promising results in managing hirsutism and acne, though specific response rates were not uniformly reported. Pharmacological therapies are essential for addressing hormonal imbalances and metabolic dysfunctions.
• Combination Therapies: Five studies comprising 230 patients reported the highest success rates (70%-80%) for combined approaches. Therapies such as lifestyle changes paired with metformin or OCs showed substantial improvements in ovulation, menstrual regularity, and insulin sensitivity. Myo-inositol combined with alpha-lipoic acid reduced insulin resistance by 65%. These findings underscore the synergistic benefits of integrating lifestyle and pharmacological interventions.
Conclusions
Combination therapies achieve the highest success rates in managing PCOS in adolescents, while lifestyle modifications remain foundational. Pharmacological treatments, particularly metformin and OCs, effectively address hormonal and metabolic dysfunction. This review emphasizes the importance of individualized, early interventions to optimize outcomes. Further research should focus on the long-term efficacy of these treatments and emerging therapeutic options.
Recommendations
• Tailored combination therapies with lifestyle modifications and pharmacological treatments improve outcomes in adolescents with PCOS.
• Long-term studies are needed to assess treatment durability and explore novel interventions.

Does hormonal cross-talk exists between different endocrine glands: an indian prospective study of this unique phenomenon

Ramakanth Bhargav Panchangam[1], Sabaretnam Mayilvaganan[2], Rajesh Bangaraiahgari[3], Ramesh Bangaraiahgari[3], Vidya Paboju[3], Kundana Sree K M[3], Amith Anshuli Dubey[3], Varshitha Eadula[3], Laxmi Narayana Sripuram[3] & Sushmitha Sree Mekala[3]
[1]BGH, Vijayawada, India; [2]SGPGIMS, Lucknow, India; [3]TRR institute of medical sciences, Hyderabad, India

Background
Endocrine system (ES) is distinct amongst all organ systems (OS) in human body. ES is a conglomeration of different endocrine organs. So far, the only models of proof of physiological cohesiveness between anatomically separated endocrine glands within ES are APUD cell concept; HPA axis; HPG axis; biochemical pathways of hormones. We wanted to investigate a hypothesis, that there is hormonal inter-dependance between different endocrine organs. We took nontoxic goiter (thyroid) and primary hyperparathyroidism as prototypes.
Material and Methods
This prospective case-control study was conducted on 200 cases (175 thyroid and 25 parathyroid) and age matched 200 controls from healthy blood donors over a period of 12 months. Institutional ethical committee approval was obtained. All thyroid and parathyroid cases underwent uneventful curative thyroidectomy and parathyroidectomy respectively. Exclusion criteria were subjects with any febrile illness, candidates with stress, anxiety neurosis, allergies, chronic drug use, diabetes, systemic or chronic inflammatory disease or calcium/vitamin D supplements, any medication which interferes with the normal function of the hypothalamic-pituitary axis, menopausal age group. Serum samples were collected preoperatively, from all the subjects in both groups as per the standard collection times and procedures. Statistical analysis was performed by SPSS 20.0. P = value of < 0.05 was considered significant.
Results
Mean prolactin, Luteinising hormone (LH), follicular stimulating hormone (FSH), parathormone, cortisol and testesterone in thyroid cases and controls were 27.6 $\pm$ 8.1 ng/ml (12 – 87), 24.5 $\pm$ 1.7 IU/l(10– 57), 16.8 $\pm$ 3.3 IU/l(8.4 – 41), 24.5 $\pm$ 3.9 pg/ml (15 – 65), 7.1 $\pm$ 2.5 mg/dl (4- 16.5), 257 $\pm$ 56 ng/dl(167 – 478) and 14.6 $\pm$ 3.5 ng/ml (8 – 18), 11.4 $\pm$ 2.5 IU/l(2.5 – 12.5), 6.1 $\pm$ 2.9 IU/l(3.5 – 21), 21.2 $\pm$5.3 pg/ml (9 – 46), 11.3 $\pm$ 3.6 mg/dl (5.5- 19), 214 $\pm$ 45 ng/dl (115 – 368) respectively. There was statistically significant difference of prolactin, LH, FSH and cortisol values between thyroid cases and controls. But statistical difference was significant only for prolactin, FSH and LH between parathyroid cases and controls.
Conclusions
This study highlights an unique model of endocrine homeostasis and hormonal cross talk within the ES. The results provides a distinct proof to screen for subclinical endocrine diseases. But, the exact pathophysiological mechanism and significance of hormonal cross talk between varied endocrine organs needs active research.

Synchronous pheochromocytoma and papillary thyroid carcinoma - is CACNA1H the culprit?

Cristina Andreea Bordeianu[1], Sorina Schipor[1], Elena Braha[1], Andrei Muresan[1], Dan Alexandru Niculescu[1,2], Andrei Goldstein[1], Adrian Tulin[2,3] & Madalina Daniela Lucia Musat[1,2,4]
[1]C.I Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Emergency Hospital Prof.Dr.Agrippa Ionescu, Bucharest, Romania; [4]National University of Science and Technology Politehnica, eBiohub Chair of Research Center in Biomedical Engineering, Bucharest, Romania

Background
Thyroid carcinoma in patients with pheochromocytoma is 14 times more likely to occur than in general population, however papillary thyroid carcinoma(PTC) has been rarely reported in association with pheochromocytoma. We present the case of a patient diagnosed with synchronous pheochromocytoma and PTC with negative genetic testing for common mutations.
Case report
A 48 years old woman with significant familial history in the oncological field presented to our clinic for a right adrenal nodular lesion accidentally discovered after an abdominal-pelvic CT scan performed for back pain. The endocrine tests revealed increased values of plasma and urinary metanephrines and nonmetanephrines and a right thyroid nodule (TIRADS-4). Fine-needle aspiration biopsy showed atypia of undetermined significance (Bethesda 3). The patient has been subject of right adrenalectomy and subsequent total thyroidectomy. Immunohistochemistry of adrenal tumor showed pheochromocytoma, PASS score = 8, suggestive of aggressive tumor behavior, chromogranin A diffuse positivity in the tumor and Ki-67 = 7%. Thyroid histopathological report revealed unifocal right PTC, pT1bN0, low risk group. The patient was screened for germline mutations by next-generation sequencing (TruSight One Sequencing panel, Illumina) for a panel of 4813 genes including: *RET*, *SDHx, VHL, TMEM, MAX* and many other

susceptibility genes cited in current literature as being involved in genetic etiology of pheocromocytoma. The analysis could not find any pathogenic or likely pathogenic variants related to the phenotype. Instead, we found a monoallelic missense variant of uncertain significance in a gene for calcium voltage-gated channel subunit 1G, *CACNA1G* (NM_018896.5): c.1382G>A (p.Arg461Gln). The alpha 1 subunit of the family of T-type low voltage-operated calcium channels (VOCCs) includes three isoforms encoded by the genes *CACNA1G* (CaV3.1), *CACNA1H* (CaV3.2), and *CACNA1I* (CaV3.3). *CACNA1H* variants have recently been associated with pheochromocytoma (1). The particularity of the case is the association between adrenal paraganglioma and PTC, together with the oncological family history. Although pheochromocytomas secrete mainly catecholamines and their metabolites, they can also secrete many other peptides such as insulin-like growth factor II, that might cause the development and growth of papillary thyroid carcinoma. However these do not explain the family history of various cancers.

Conclusions

The association of PTC and pheochromocytoma in this patient may be coincidental, but it seems more likely to result from genetic variants in genes still awaiting identification.

Co-existence of type 1 diabetes mellitus, thyroid dysfunction, and myasthenia gravis: a case report

Mouna Elleuch[1], Malek Hadrich[1], Fourati Zeineb[1], Moalla Khadija[2], Ameni Ben Abdallah[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Department of Endocrinology Hedi Chaker Hospital, Sfax, Tunisia; [2]Department of Neurology Habib Bourguiba, Sfax, Tunisia

Introduction

Autoimmune diseases share a common predisposition and can coexist in the same patient. Type 1 diabetes, hyperthyroidism, and myasthenia gravis have similar immunopathological bases. The coexistence of these three conditions is rarely reported in the literature but has significant diagnostic, therapeutic, and prognostic implications. We report a case of this association.

Case Report

A 23-year-old male was diagnosed with type 1 diabetes in December 2022 at the age of 21 and he was managed with a basal-bolus insulin regimen. During follow-up, he reported progressive fatigue worsening throughout the day and dysphagia. Clinical examination revealed left eyelid ptosis, leading to a diagnosis of myasthenia gravis in February 2023. He was hospitalized in the neurology department and treated with pyridostigmine 480 mg/day and corticosteroids, with good clinical improvement. During a subsequent hospitalization in June 2023, the patient presented with weight loss, polyphagia, palpitations, and diarrhea. Examination revealed a small, homogeneous goiter, inactive bilateral exophthalmos, and distal tremors. Laboratory tests showed TSH < 0.014 µUI/ml, FT4: 88.4 pmol/l,positive anti-TPO antibodies at 90.8 UI/ml, negative anti-TG antibodies. Based on these findings, Graves' disease was suspected, and the patient was started on thiamazole 30 mg/day and propranolol 120 mg/day.

Conclusion

These conditions highlight the complex interplay between autoimmunity, genetics, and immune dysfunction. A gene associated with early-stage type 1 diabetes and myasthenia gravis (sialitis and peri-insulitis) has been mapped to chromosome 1 near the Bcl-2 locus. Additionally, the CTSL2 gene, encoding cathepsin V, a cysteine protease involved in antigen presentation in human cortical thymic epithelial cells, may play a role in the autoimmunity of these three diseases. A personalized approach is essential for diagnosis, treatment, and long-term follow-up of these patients.

A clinical case of a patient with alstrom's disease in the practice of an endocrinologist

Anastasia Myakota[1], Anastasia Zvyagintseva[1] & Saida Ibragimova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Objective

Alstrom syndrome is a hereditary disorder caused by a double dose of a mutated gene. This leads to clinical manifestations including retinal degeneration (resulting in blindness), obesity, TD2M, neurosensory hearing loss, and early-onset dilated cardiomyopathy. Currently, only one gene has been identified as causing this syndrome: ALMS1. We present a clinical case of a patient with Alstrom syndrome as encountered by an endocrinologist.

Materials and Methods

Patient A.A., an 18-year-old male, presented to the endocrinologist complaining of a 3-4 kg weight gain over the past 6 months, decreased visual acuity since childhood, photophobia, hearing loss, and short stature. At age 1 year, an ophthalmological examination revealed nystagmus, photophobia, low visual acuity and hereditary retinal dystrophy and mixed astigmatis. Usher syndrome was suspected but excluded through genetic testing. He has been overweight since childhood. At age 14, an audiological examination revealed grade 2 progressive neurosensory hearing loss. At age 17, he consulted an endocrinologist due to short stature (158 cm). His father is 180 cm tall, his mother 164 cm, his older brother 189 cm. Hand X-rays showed a bone age consistent with 17-18 years. Pituitary MRI revealed no adenoma. At age 18, Alstrom syndrome was genetically confirmed. In 2024, at Endocrinology Research Center the examination revealed a weight of 85.4 kg, height of 158 cm, and BMI of 34.1 kg/m^2. He had brown striae on his upper extremities, minimal body and facial hair, and firm breasts on palpation. Hormonal testing excluded endocrine causes of obesity (endogenius hypercortisolism, hyperprolactinemia, and hypothyroidism). Normogonadotropic hypogonadism was diagnosed (LH 5.6 IU/l,FSH 11.6 IU/l,total testosterone 4.85 nmol/L). An urological consultation diagnosed secretory infertility, and hormone replacement therapy was recommended. Growth hormone deficiency was ruled out (GH 0.18 ng/ml, IGF-1 260.8 ng/ml). There was no evidence of impaired glucose metabolism. Orlistat was recommended to manage his weight and prevent progression of dysmetabolic complications. An ophthalmological consultation confirmed Alstrom-Hallgren syndrome, with findings of tapetretinal abiotrophy, partial optic nerve atrophy, horizontal nystagmus, convergent strabismus, and early posterior capsular cataract. Significantly, ECG did not reveal dilated cardiomyopathy.

Conclusion

The ALMS1 gene mutation underlies the patient's reduced vision, hearing, obesity, diabetes, and short stature, significantly impacting his quality of life and lifespan. This presents a significant social problem. This clinical case highlights the importance of early diagnosis of genetic disorders by primary care physicians and the need for a multidisciplinary approach in managing patients with rare diseases.

Hormonal impacts of energy drinks on adolescents: a comprehensive review

Shaymaa Elsayed[1], Dina Fawzy[1], Ashraf Soliman[2], Ahmed Elawwa[1], Fawzia Alyafei[2], Nada Alaaraj[2] & Noor Hamed[2]
[1]Pediatric Endocrinology and Diabetology Unit, Alexandria University, Alexandria, Egypt; [2]Department of Pediatrics, Hamad General Hospital, Doha, Qatar

Background

Energy drink consumption among adolescents has increased significantly in recent years, raising concerns about its potential effects on hormonal balance and overall health. These beverages, typically high in caffeine and sugar, can disrupt crucial hormonal processes during adolescence—a critical period for growth, reproductive development, and maturation. This review examines the effects of energy drinks on cortisol, melatonin, insulin, growth hormone (GH), testosterone, and reproductive function.

Objectives

The aim is to evaluate the hormonal disruptions caused by energy drinks in adolescents and to discuss the implications of these disruptions on adolescent growth, reproductive health, and stress regulation.

Methods

A comprehensive review of peer-reviewed studies published between 2000 and 2024 was conducted. Articles were selected based on their focus on energy drink consumption and its impact on hormonal regulation in adolescents. Studies were reviewed for their methodology, participant demographics, and reported outcomes.

Results

Adolescents consuming energy drinks are at risk of significant hormonal imbalances that may impair growth, stress regulation, and reproductive health. Excessive caffeine intake elevates cortisol levels, leading to increased stress and

potential suppression of reproductive hormones. Caffeine delays melatonin production, disrupting sleep-wake cycles and reducing sleep quality. High sugar content impairs insulin sensitivity, increasing the risk of metabolic disorders like diabetes. Poor sleep quality suppresses GH secretion, critical for linear growth and puberty-related growth spurts. Elevated cortisol and disrupted sleep patterns may suppress testosterone production, delaying puberty in boys. Energy drinks' high caffeine and sugar content may reduce sperm motility and count by increasing oxidative stress..
Conclusion
Energy drinks can disrupt hormonal balance in adolescents, affecting cortisol, melatonin, testosterone, and reproductive function. Limiting intake and educating adolescents and parents about these risks is critical to supporting healthy growth and development.

Hereditary xerocytosis and secondary haemochromatosis - a rare cause of progressive endocrine dysfunction

Andra Ionescu[1], Simona Manole[2,3] & Cristina Alina Silaghi[1,2]
[1]Cluj County Emergency Hospital, Endocrinology, Cluj-Napoca, Romania; [2]"Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]"Niculae Stancioiu" Heart Institute, Radiology and Medical Imaging, Cluj-Napoca, Romania

Hereditary xerocytosis (HX), or dehydrated hereditary stomatocytosis, is a rare haemolytic anaemia caused by gain-of-function mutations in the *PIEZO1* gene, located on chromosome 16q23-24. The *PIEZO1* gene encodes the PIEZO1 protein, a mechanosensitive cation channel that regulates cell volume and is highly expressed in the red blood cell (RBC) plasma membrane. In HX, mutations disrupt ion transport, causing excessive calcium influx. Elevated intracellular calcium activates the Gardos channels, leading to significant potassium efflux and water loss. These changes cause RBC dehydration, reduced deformability, shortened lifespan, and eventual apoptosis. We report the case of a 22-year-old male with a complex medical history. At 16 years old, he was referred to the endocrinology department for delayed puberty. Laboratory investigations revealed low levels of luteinizing hormone, follicle-stimulating hormone, and testosterone, alongside a negative response to the gonadotropin-releasing hormone agonist stimulation test. He was diagnosed with hypogonadotropic hypogonadism and prescribed testosterone therapy. His medical history also included haemolytic anaemia, initially diagnosed as hereditary spherocytosis at the age of 6, which required intermittent red blood cell transfusions. He underwent splenectomy at the age of 9, followed by cholecystectomy at 13 due to cholelithiasis and mechanical jaundice. Despite the splenectomy, haemolysis persisted, and sporadic transfusion requirement continued. At 22 years old, the patient developed non-autoimmune diabetes mellitus and growth hormone deficiency, prompting an evaluation for iron overload. Laboratory investigations revealed ferritin levels exceeding 700 ng/ml and a transferrin saturation of 81%. Given the atypical progression of haemolysis and the new endocrine complications, genetic testing was subsequently performed, identifying a heterozygous mutation in *PIEZO1* c.7483_7488dup, p.(Leu2495_Glu2496dup), affecting the C-terminal region of the *PIEZO1* gene. This confirmed a diagnosis of HX, providing a unifying explanation for the patient's hematologic and endocrine findings. Assessement by T2* magnetic resonance imaging (MRI) showed significant iron overload in the heart, liver and pancreas. Iron chelation therapy and annual MRI evaluation are advised. The phenotypic variability of rare haemolytic anaemias may lead to misdiagnosis and suboptimal treatment. Accurate diagnosis is critical, as it directly impacts patient management. HX, as demonstrated in this case, can be misdiagnosed as hereditary spherocytosis due to overlapping clinical features. However, unlike hereditary spherocytosis, in which splenectomy is a cornerstone of treatment, splenectomy is contraindicated in HX because of the increased risk of thromboembolic complications. This highlights the importance of molecular diagnostics in guiding personalized management, helping to prevent therapeutic missteps, and improving long-term outcomes.

Pseudohypoparathyroidism due to GNAS inactivation: a case report

Huy?n Đ?ng[1], Dung Vu[1], Thao Bui[1], Ngoc Can[1] & Khanh Nguyen[1]
[1]Center for Endocrinology, Metabolism, Genetics and Molecular Therapy, Viet Nam National Children's Hospital, Ha Noi, Viet Nam

Background
Pseudohypoparathyroidism (PHP) is a rare genetic disorder characterized by target organ resistance to parathyroid hormone (PTH) caused by mutations in the *GNAS* gene or other upstream targets. This condition often presents with hypocalcemia, hyperphosphatemia, and characteristic skeletal abnormalities. Due to its diverse clinical manifestations, PHP is frequently misdiagnosed, resulting in delayed treatment and increased risk of complications. We present a case of PHP initially misdiagnosed as epilepsy, highlighting the importance of recognizing hypocalcemia as a differential diagnosis in seizure disorders.
Presentation
A 9-year-old girl with a history of congenital hip dislocation and no significant family history was admitted for evaluation of recurrent seizures. No previous records of hypocalcemia were noted. Her first seizure occurred at the age of three and was diagnosed as epilepsy, leading to treatment with sodium valproate. Despite this, she continued to experience 1–2 seizures annually, which escalated to daily seizures three weeks before hospitalization. Upon neurological examination, severe hypocalcemia was identified, and the child was referred to an endocrinologist for further investigation. Physical examination identified features of Albright hereditary osteodystrophy (AHO), including a round face, short stature (-2.0 SD), central obesity (+2.6 SD), brachydactyly, scoliosis, and developmental delay. Initial laboratory results revealed severe hypocalcemia (ionized calcium: 0.65 mmol/L), hyperphosphatemia (2.97 mmol/L), normal magnesium (0.72 mmol/L), vitamin D sufficiency (78.3 ng/ml), and significantly elevated PTH levels (766 pg/ml). Additional biochemical findings included elevated TSH (20.3 mUI/l)with normal FT4 (14 pmol/L), indicating multi-hormonal resistance. The radiographic evaluation confirmed shortened metacarpal bones, left hip dislocation, hip dysplasia, bilateral femoral flattening, and tibial shortening. Genetic testing via next-generation sequencing identified a heterozygous *GNAS* variant (c.2T>C; p.Met1?), a previously unreported mutation in *GNAS*-related disorders. *ClinVar* and *In silico* analysis classified this variant as *likely pathogenic* according to ACMG/AMP guidelines. The child was treated with calcitriol (20 ng/kg/day), oral calcium, and levothyroxine. Following treatment, seizures ceased completely, PTH and TSH levels normalized, and the patient showed a significant height increase of 6.5 cm over nine months (-2.0 SD to -1.5 SD).
Conclusion
This case highlights the diagnostic challenges of PHP, particularly in patients presenting with neurological symptoms such as seizures. We emphasize the importance of serum calcium, phosphate, and PTH evaluation in children with unexplained seizures or AHO-like features. Genetic analysis can provide diagnostic confirmation in ambiguous cases, guiding appropriate management and improving patient outcomes.
Keywords
Pseudohypoparathyroidism, *GNAS* mutation, hypocalcemia, Albright hereditary osteodystrophy.

Unraveling biological determinants of advanced fibrosis risk in type 2 diabetes patients with MASLD

Yesmine Elloumi[1], Mouna Elleuch[1], Yasmine Abdelkafi[1], Nada Hassairi[1], Kouloud Boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Metabolic-Associated Steatotic Liver Disease (MASLD) is increasingly prevalent among patients with Type 2 Diabetes Mellitus (T2DM), often leading to advanced fibrosis. Identifying biological factors that influence fibrosis risk in this population is crucial for improving patient outcomes. This study aims to explore the key biological determinants associated with advanced fibrosis in T2DM patients with MASLD.
Methods
We realized a comparative and analytical study including T2DM patients with confirmed MASLD, followed at the Endocrinology-Diabetology Department of Hedi Chaker University Hospital in Sfax, Tunisia. We used the fibrosis-4 index (FIB-4) and the NAFLD fibrosis score (NFS) to evaluate the risk of advanced fibrosis among patients. High risk of advanced fibrosis was indicated by a FIB-4 score exceeding 2.67 and an NFS score exceeding 0.675. The patients were categorized into two groups: a high-risk group for advanced fibrosis and an intermediate and low-risk group.

Results
101 T2DM patients with MASLD were included. Liver enzymes and platelet count were excluded from the analysis as they are integral components of the NFS and FIB-4 scores. When groups were formed based on the NFS score, the prothrombin level was significantly lower in the high-risk advanced fibrosis group compared to the other group (78.0 [50.0-98.0] vs. 99.0 [94.0-100.0], respectively; $P = 0.008$). Comparison of groups based on the FIB-4 score did not confirm this significant difference in prothrombin level but revealed other significant associations: elevated alkaline phosphatase levels were linked to a higher risk of advanced fibrosis ($P = 0.033$), and albumin levels were lower in the high-risk group ($P = 0.041$). Other biological parameters, including total bilirubin, conjugated bilirubin, gamma-glutamyl transferase, thyroid-stimulating hormone, and uric acid, were not associated with advanced fibrosis risk regardless of the scoring method used.
Conclusion
Biological parameters such are crucial for assessing fibrosis risk in T2DM patients with MASLD, highlighting the need for comprehensive biomarker evaluation in this population.

Autoimmune polyendocrine syndrome type 1 or acquired immunodeficiency syndrome? a complex case of type 1 diabetes, hypoparathyroidism, and hiv infection

Younes Derbel[1], Wiem Saafi[2], Hamza Elfekih[1], Malek Hadrich[2], Imen Halloul[2], Ach Taieb[2], Ghada Saad[2] & Yosra Hasni[2]
[1]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Endocrinology and Diabetology Department, Sousse, Tunisia; [1]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Endocrinology and Diabetology Department, Sousse, Tunisia

Introduction
Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) syndrome is a rare autosomal recessive disorder caused by mutations in the *AIRE* gene. It is characterized by the triad of chronic mucocutaneous candidiasis, hypoparathyroidism, and adrenal insufficiency. We report the case of a 33-year-old male suspected to have this rare syndrome and who was diagnosed with an underlying human immunodeficiency virus (HIV) infection.
Case presentation
We present a case report of a 33-year-old male admitted to our department for the management of poorly controlled type 1 diabetes mellitus (T1DM), with a hemoglobin A1c level of 10%, progressing over five years. Initially, the patient was placed on a basal-bolus insulin regimen; however, he self-discontinued rapid-acting insulin and reduced the dosage of long-acting insulin due to recurrent hypoglycemic episodes accompanied by recent weight loss. His medical history included a gastric ulcer and esophageal candidiasis. Laboratory investigations upon admission revealed hypocalcemia at 1.64 mmol/l(reference range:2.20-2.65mmol/l) and hyperphosphatemia at1.8 mmol/l(reference range:08-1.40 mmol/l), with normal magnesium levels. Further analysis demonstrated a low parathyroid hormone (PTH) level of 11 pg/ml (reference range: 15–65 pg/ml) and a slightly low vitamin D level of 26.8 ng/ml, consistent with a diagnosis of primary hypoparathyroidism. The coexistence of primary hypoparathyroidism and esophageal candidiasis raised suspicion for APECED syndrome, particularly given the patient's autoimmune T1DM background. Diagnostic evaluations ruled out adrenal insufficiency via a Synacthen test, and autoimmune screening for celiac disease yielded negative results. During hospitalization, the patient developed inflammatory arthralgias in the wrists and ankles. A detailed clinical history revealed unprotected sexual encounters, prompting comprehensive immunological and infectious evaluations. While immunological tests were unremarkable, serological testing identified an underlying HIV infection. The presence of esophageal candidiasis led to the diagnosis of acquired immunodeficiency syndrome (AIDS).
Conclusion
This case illustrates the diagnostic complexity of differentiating APECED syndrome from immunodeficiency disorders such as AIDS, particularly in patients with overlapping clinical features such as hypoparathyroidism and recurrent infections like esophageal candidiasis. The unexpected diagnosis of HIV infection in this patient underscores the necessity of considering infectious etiologies in the differential diagnosis of polyendocrine disorders, even in the presence of autoimmune conditions like T1DM.

Hypercortisolemia and its impact on type 2 diabetes

Marin Pecani[1] & Paola Andreozzi[2]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]University Hospital Policlinico Umberto I, Sapienza University of Rome, Rome, Italy

Introduction
Cushing's syndrome (CS) is a rare endocrinopathy characterized by prolonged hypercortisolism, which can arise from several etiologies. Due to its heterogeneous clinical presentation and overlap with other conditions, the diagnosis of CS is often delayed, sometimes for years after the initial onset of symptoms.
Case report
A 56-year-old woman with a medical history of type 2 diabetes (T2D), hypertension (HTN), dyslipidemia, and osteopenia presents for follow-up in our outpatient clinic, referred by her primary care physician. Her treatment plan included metformin and dapagliflozin for T2D, irbesartan and amlodipine for HTN, atorvastatin for dyslipidemia, and vitamin D for osteopenia. Her primary complaints included generalized weakness and difficulty losing weight despite following a low-carbohydrate diet. Additionally, she reported gradual weight gain over the past four years, particularly in the abdominal region. Her BMI had increased from 29.1 kg/m^2 to 34.2 kg/m^2, and her waist circumference measured 109 cm. At the time of assessment, her blood pressure was 145/95 mmHg, and her glycated hemoglobin (HbA1c) was 8.6%. Consequently, hydrochlorothiazide and semaglutide were added to her regimen to address her blood pressure and glycemic control. After three months, the patient's HbA1c increased slightly to 8.8%, and her blood pressure was 141/88 mmHg. A complete blood count and metabolic panel were ordered, along with fasting and postprandial blood glucose tests. While the patient's fasting blood glucose ranged from 115 to 132 mg/dl, her postprandial glucose levels were notably elevated, reaching up to 280 mg/dl, particularly after lunch and dinner. Considering these findings, the patient underwent morning cortisol and ACTH testing, which revealed low ACTH and elevated cortisol levels. A low-dose dexamethasone suppression test showed no significant decrease in cortisol levels (4.78 µg/dl). An abdominal computed tomography (CT) scan was then conducted, identifying a 2.4 cm left adrenal nodule, consistent with an adrenal adenoma, while the right adrenal gland appeared normal. The patient was referred to an endocrine surgeon, and a minimally invasive adrenalectomy was scheduled three months later. Throughout this period, her blood glucose and blood pressure were carefully managed. Postoperative histopathology confirmed the presence of an adrenal adenoma, with no evidence of malignancy.
Conclusion
This case underscores the importance of considering hypercortisolism as a differential diagnosis in patients with T2D who struggle with achieving optimal blood glucose control. Clinicians should remain vigilant in identifying such conditions, as they can complicate the management of diabetes and other comorbidities, undermining treatment effectiveness and patient outcomes.

A rare coexistence of auto-immune diabetes mellitus with collagenous colitis and scleroderma: a case report

Meryam Alahyane[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakesh, Morocco

Introduction and Background
The coexistence of multiple autoimmune diseases either systemic or organ-specific has been described in the literature. Here, we report a case of Latent Autoimmune Diabetes in Adults (LADA) associated with cutaneous systemic scleroderma (SSc), a rare and scarcely documented entity.
Case Report
A 41-year-old man, diagnosed with LADA two years prior, was treated with a basal-bolus insulin regimen. Concurrently, the patient developed symptoms of malabsorption, including chronic non-bloody watery diarrhea, abdominal pain, weight loss, iron deficiency anemia, hypoalbuminemia, and significant glycemic instability. Auto immune Adrenal insufficiency, thyroidis, and celiac disease were excluded. Colonoscopy with biopsy confirmed the diagnosis of microscopic colitis, collagenous subtype. Two years later, the patient presented with progressive diffuse thickening and hardening of the skin, accompanied by limited

joint mobility, particularly in the lower limbs.A cutaneous biopsy revealed sclerodermiform features, with significant fibrosis and no evidence of malignancy, consistent with systemic sclerosis.
Discussion
Collagenous colitis, one of the primary subtypes of microscopic colitis (MC), is a chronic inflammatory condition of the colon characterized by watery diarrhea. Although the exact etiology remains unclear, autoimmune dysfunction has been strongly involved, as evidenced by its association with various autoimmune comorbidities. Auto-immune diabetes caracterized by the destruction of pancreatic β-cells, has also been linked to MC. A nationwide matched case–control study in Sweden reported an 80% increased prevalence of Type 1 Diabetes in MC patients compared to the general population, with a stronger association observed for collagenous colitis than lymphocytic colitis. Systemic sclerosis (SSc) is an autoimmune connective tissue disorder marked by fibrosis and commonly presenting with skin involvement. Cases of coexistence between autoimmune diabetes and SSc are rare, and the underlying mechanisms remain poorly understood. Interferons are believed to play a significant role as immunomodulators and inhibitors of collagen production. In this case, the histopathology was characteristic of systemic sclerosis. However, distinguishing between diffuse skin hardening caused by systemic sclerosis and other conditions, such as scleroderma-like syndrome or diabetic scleroderma, can be challenging. Diabetic scleroderma is attributed to the non-enzymatic glycation of collagen. Chronic hyperglycemia may stimulate fibroblast proliferation and extracellular matrix production, contributing to skin hardening.
Conclusion
This case highlights the need to recognize rare autoimmune associations and integrate routine screening for comorbidities in patients with autoimmune backgrounds. Further research is needed to elucidate underlying mechanisms and improve therapeutic approaches.

Unexplained recurrent paronychia: a closer look at an overlooked diagnosis

Sara Soldovieri[1,2], Lara Devilli[1,2], Emanuela Pignatone[1,2], Renato Vaiasuso[1,2], Franco Ricci[2] & Stefano Stagi[1,2]
[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Auxoendocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy

Background
Pseudohypoparathyroidism (PHP) and related disorders are a group of rare diseases associated with the phenotype known as Albright's hereditary osteodystrophy (AHO), which includes round face, short stature, brachydactyly, ectopic ossifications, and intellectual disability. These conditions are caused by heterozygous inactivating mutations in the GNAS gene, leading to resistance to hormones acting via G protein-coupled receptors. The diagnosis is often delayed as the phenotypic features and hormonal resistance become apparent over time, with subtle manifestations in early childhood.
Case Presentation
We describe the case of a 9-year-old girl who was followed at the Endocrinology Department for stunted growth. Born at 32 weeks with intrauterine growth restriction, at the age of 2 years she was diagnosed with celiac disease and hypothyroidism with negative thyroid autoimmunity and normal gland position. The chromosomal microarray (CMA) did not reveal any genomic imbalances and the genetic testing for SHOX gene mutations was negative. She underwent surgery for right thumb paronychia with associated onychodystrophy at the age of 4. At the age of 5, idiopathic central precocious puberty was diagnosed, and pubertal suppression was initiated. At 7 years, her height relative to bone age was at -3 Standard Deviation Score while a disproportionate growth pattern and an abnormal shortening of the fourth metacarpal became apparent. At 8.5 years, she had a recurrent episode of paronychia affecting the foot. Skeletal X-rays showed dysmorphic features of metacarpals, metatarsals, and phalanges, along with ossifications in the soft tissues around the right big toe and the retrocalcaneal area on the left. These findings were consistent with skeletal dysplasia. Next-generation sequencing revealed a pathogenic *de novo* variant in the GNAS gene (c.1102_1125del, p.Asp368_Val375del) located in exon 13. Genetic analysis and radiological investigations ultimately revealed that the recurrent episodes of paronychia were, indeed, heterotopic ossifications, a hallmark feature of Albright hereditary osteodystrophy.
Conclusions
This case underscores the diagnostic challenges of PHP-related disorders in children, in which phenotypic features may be subtle or misinterpreted. Hypothyroidism, with a normally positioned thyroid gland, is one of the earliest signs, along with ectopic ossifications, which should be actively investigated, particularly in periarticular areas, hands, and plantar region. Additionally, even in syndromic short stature cases, precocious puberty can occur and mask the underlying condition. Awareness of AHO and its hallmark features, along with early genetic testing, are crucial for prompt diagnosis and timely management.

The role of MRI and ferriscan in diagnosing and managing endocrine and growth complications in thalassemia major

Shayma Ahmed[1], Ashraf Soliman[1], Nada Alaaraj[1], Noor Hamed[1], Noora AlHumaidi[1], Fawzia Alyafei[1], Abbas Noureldin[1] & Elsaid Bedair[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Patients with thalassemia major are at high risk of endocrine dysfunction and growth impairments due to iron overload in multiple organs. Accurate assessment of iron deposition is crucial for optimizing chelation therapy and mitigating complications. MRI T2* and Ferriscan have emerged as reliable, non-invasive tools for quantifying liver iron concentration (LIC) and detecting iron deposition in endocrine organs.
Objective
This review highlights the benefits of MRI and Ferriscan in diagnosing and managing endocrine and growth abnormalities in thalassemia major by analyzing findings from the past two decades.
Material and Methods
Twenty studies from 2006 to 2023 were reviewed, including a total of over 1,500 patients with thalassemia major. Data were synthesized on MRI T2* and Ferriscan applications for assessing iron burden in endocrine-related organs (pituitary, liver, pancreas, and heart), as well as their correlation with clinical outcomes.
Results
1. Liver Iron Concentration (LIC): Ferriscan consistently demonstrated high accuracy in LIC quantification, outperforming serum ferritin in patients with moderate-to-severe iron overload (Padeniya *et al*., 2020; Kildemoes *et al*., 2023). LIC monitoring significantly improved chelation therapy adherence and reduced overall iron burden (Calvaruso *et al*., 2014; Nichols-Vinueza *et al*., 2014).
2. Pituitary Iron and Endocrine Dysfunction: MRI T2* reliably detected pituitary iron deposition, correlating with hypogonadotropic hypogonadism and growth hormone deficiency (Wang *et al*., 2006; Morad *et al*., 2021).
3. Pancreatic Iron and Diabetes Risk: Pancreatic T2* showed early iron overload, enabling timely intervention to reduce diabetes risk (Au *et al*., 2007).
4. Cardiac and Multiorgan Correlations: MRI T2* effectively predicted cardiac iron, reducing cardiac events through tailored chelation (Farhangi *et al*., 2017; Nichols-Vinueza *et al*., 2013).
5. Correlation with Endocrinopathies: Higher LIC and cardiac iron levels strongly correlated with endocrine complications, emphasizing the importance of comprehensive iron monitoring (Kanbour *et al*., 2018; Chirico *et al*., 2015).
Discussion
MRI T2* and Ferriscan are indispensable in assessing iron deposition and guiding treatment strategies in thalassemia major. By accurately quantifying organ-specific iron levels, they enable early detection and management of endocrine dysfunction, improving growth outcomes and reducing complications.
Conclusion
MRI and Ferriscan significantly enhance diagnostic accuracy and management of endocrine and growth abnormalities in thalassemia major. Their routine use is essential for optimizing patient outcomes by tailoring chelation therapy to mitigate iron overload and prevent long-term complications.

The Unique features of growth and endocrine changes in patients with sickle ß-thalassemia

Ashraf Soliman[1], Sohair Elsiddig[1], Shayma Ahmed[1], Ahmed Elawwa[1], Nada Alaaraj[1], Noor Hamed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Sickle cell/β-thalassemia (HbS/β-thal) is a rare hemoglobinopathy caused by compound heterozygosity for mutations in the β-globin gene. It encompasses two

significant types: HbS/β?-thalassemia (complete absence of β-globin production) and HbS/β?-thalassemia (partial β-globin synthesis). The condition exhibits significant clinical heterogeneity, with an estimated global prevalence of 1.5% in regions with high rates of hemoglobinopathies.
Objective
This review aims to synthesize findings on the unique growth and endocrine alterations observed in patients with HbS/β-thal, emphasizing their relationship with disease severity and pathophysiological mechanisms.
Methods
A comprehensive table of findings from multiple studies focusing exclusively on HbS/β-thalassemia patients was reviewed, highlighting clinical and laboratory observations related to growth and endocrine dysfunction.
Results
1. Growth Impairment:.
• Patients with HbS/β?-thal showed significantly lower body mass index (BMI) and higher malnutrition rates than HbS/β?-thal patients, with a strong correlation between BMI and hemoglobin levels.
• Bone mineral density (BMD) was notably reduced in HbS/β? patients, reflecting heightened susceptibility to osteoporosis and osteopenia due to chronic hemolysis, inflammation, and endocrine disruption.
2. Endocrine Dysfunction:.
• HbS/β? patients exhibited more profound hypogonadism, characterized by reduced levels of luteinizing hormone (LH) and follicle-stimulating hormone (FSH), alongside poor gonadal response.
• Delayed puberty and reduced insulin-like growth factor-1 (IGF-1) levels were observed in both HbS/β? and HbS/β? patients, linked to iron overload and pituitary damage.
• HbS/β^+ patients were more prone to acute chest syndrome, possibly due to elevated BMI and hemoglobin levels, which may exacerbate blood viscosity and complications.
Conclusion
The growth and endocrine alterations in HbS/β-thal patients are multifactorial, stemming from anemia, chronic inflammation, iron overload, and mutation severity. HbS/β?-thal patients typically experience more severe outcomes, with marked growth retardation, lower BMI, and extensive endocrine dysfunction. Early interventions, including chelation therapy and endocrine management, are critical to improving the quality of life and mitigating complications in these patients. Future research should explore individualized therapeutic approaches for these unique phenotypes. Table 1: Summary of HbS/β-Thalassemia Studies.

Table: Key Growth and Endocrine Features of HbS/β-Thalassemia Phenotypes.

Phenotype	Growth Findings	Endocrine Findings
HbS/B0Thal	Lower BMI, severe growth impairment, reduced BMD, delayed puberty	Hypogonadism, reduced IGF-1, pituitary dysfunction, severe anemia impact
HbS/B+Thal	Higher BMI, less severe growth retardation	Milder endocrine dysfunction, prone to acute chest syndrome due to higher Hb levels

Unravelling the connection: papillary thyroid carcinoma in MEN1 syndrome
Lih Ming Loh[1] & Kristy Tian [1]
[1]Singapore General Hospital, Endocrinology, Singapore, Singapore

Background
Recent studies have highlighted a notable incidence of papillary thyroid carcinoma (PTC) in patients with multiple endocrine neoplasia type 1 (MEN1).
Case Presentation
We present the case of a 34-year-old Chinese male diagnosed with MEN1 R527X nonsense mutation through genetic screening. Although the patient was asymptomatic, laboratory investigations revealed primary hyperparathyroidism. He underwent total parathyroidectomy with deltoid implantation. Intraoperative frozen section analysis identified follicular cells in the lymph nodes of the tracheoesophageal groove. Subsequent total thyroidectomy confirmed the presence of multifocal papillary thyroid microcarcinoma. Importantly, no lymphovascular invasion, perineural invasion or extrathyroidal extension was observed.
Discussion
MEN1 is a hereditary tumor syndrome predominantly linked to endocrine tumors, including primary hyperparathyroidism, pancreatic neuroendocrine tumors, and pituitary adenomas. Nonsense mutations, such as R527X, lead to premature termination of protein synthesis, producing a truncated menin protein that loses its tumor-suppressive function, thereby increasing susceptibility to tumors. A recent study identified a 4.52% incidence of PTC in MEN1 patients, surpassing the rate in the general population . While menin is expressed in thyroid tissues, evidence of retained heterozygosity at the *MEN1* locus in PTC suggests that *MEN1* gene deletion is not directly involved in the PTC oncogenesis . PTC in MEN1 patients is often diagnosed incidentally during comprehensive surveillance for various endocrine tumors or during surgical interventions for other MEN1-related tumors. Additionally, it is possible that genetic or epigenetic factors independent of *MEN1* gene mutations contribute to the increased incidence of PTC in MEN1 patients.
Conclusion
Although the incidence of PTC is elevated in MEN1 patients, current evidence suggests that *MEN1* gene mutations do not directly cause the development of PTC. Further research is needed to explore the potential genetic or epigenetic mechanisms involved.

Growth and puberty of children living HIV/AIDS in a reference service in northeastern brazil
carla cilene nascimento castro[1], Wellington Rodrigo de Melo[1], Marcos Antonio Pereira[1], Maria dos Remédios Branco[1], Rossana Azulay[1], Jairo Morais[2], Carlos Corbett[3], Mônica Gama[1,3] & Débora Lago[1,3]
[1]Universidade Federal do Maranhão, São Luis, Brazil; [2]UNILAB, Ceará, Brazil; [3]Universidade de São Paulo - USP, Patologia, São Paulo, Brazil

Human immunodeficiency virus (HIV) infection is a highly relevant pediatric pathology worldwide. Due to metabolic alterations inherent to the disease and factors related to treatment, children living with HIV/AIDS may present growth alterations and delayed pubertal development. Early introduction of antiretroviral therapy (ART) has increased the survival rate of this population and improved the anthropometric prognosis of infected children and adolescents. The study is justified by the scarcity of current data on the subject of the global pediatric population and aims to evaluate the growth and pubertal development of children and adolescents living with HIV/AIDS followed in a specialized service in Maranhão (Northeast Brazil). This is a cross-sectional observational study that has included, to date, 76 patients, followed at the service between October 2022 and July 2024 and evaluated by a single observer. Descriptive analysis was carried out using the SPSS version 20.0 program. It was observed that the average age was 8 years, the majority were brown, with an age at diagnosis of less than one year and an average use of ART of 5.3 years. Appropriate z-score weight for age was observed in 64.5% of the population, appropriate z-score height for age in 82.9% and appropriate z-score BMI z-score in 76.3% of cases. Of the individuals evaluated, 52 (68.4%) were in the pre-pubertal phase, while 24 were in the puberty phase. Of the 24 patients already in puberty, 21 (87.5%) had normal puberty, two had precocious puberty and one had delayed puberty. For females, the average age at the onset of thelarche was 8.10 years $\pm$ 1.7, pubarche was 10 years $\pm$ 0.8, and menarche was 11.6 years $\pm$ 0.4. For males, the average age of the gonadarche was 11. 6 years $\pm$ 1.4 and that of the pubarche was 12 years $\pm$ 1.2. This study identified that the majority of children and adolescents living with HIV presented adequate growth and pubertal development.

Primary adrenal insufficiency in a patient with type 1 diabetes
Amila Čerim-Aldobašić[1], Alma Badnjević-Čengić[1], Mubina Hodžić[1] & Davorka Dautbegović-Stevanović[1]
[1]Cantonal Hospital Zenica, Department of Internal medicine/Endocrinology, Diabetes and Metabolic diseases, Zenica, Bosnia and Herzegovina

Introduction
Autoimmune diseases, such as autoimmune thyroiditis or celiac disease are frequently associated with type 1 diabetes. Adrenal insufficiency has been rarely observed but it deserves a timely diagnosis. A latent insufficiency always manifests in situations of stress, such as infection, surgery or trauma and then represents a potentially life-threatening condition.
Case presentation
In October 2024, a 36-year-old patient suffering from type 1 diabetes since the age of 12, was transferred to the Department of Endocrinology from the Department

of Surgery for further examination of suspected adrenal insufficiency. The patient's medical history revealed that he was being treated with insulin glargine U300 and prandial aspart only before lunch with good glycometabolic control according to HbA1c level (HbA1c 6.8%) but he had frequent hypoglycemic episodes in the morning, 2-3 times a week. Two weeks earlier, he had had a surgery and cholecystectomy was done due to Mirrizi's syndrome. Post-operatively, on the second day, he had ketoacidosis, which was treated in Intensive Care Unit. Due to severe pain and clinical presentation of an acute abdomen, CT scan was performed and five days after the first operation, another surgery, appendectomy, was performed. Postoperatively he presented with general weakness, hypotension, low glycaemia and hyponatremia and hypo-chloremia. Considering the discoloration of the skin, biochemistry findings and clinical presentation, adrenal insufficiency is suspected so further investigation continues at the Department of Endocrinology. The thyroid and sex hormone status was normal. Adrenal axis evaluation showed normal basal cortisol, unexpected for the postoperative period and very high ACTH levels. Cortisol levels in Synacthen test showed no increase, while adrenal insufficiency was confirmed. Antiadrenal antibodies were positive and serum levels of 21-hydroxylase antibodies were above 10 U/ml. Oral hydrocortisone at 15 mg/day divided in 2 daily doses was started. Due to normal PRA there was no need to start mineralocorticoid therapy. Continuous glycemia monitoring was performed and he was discharged from hospital. Three months later, he reported subjectively better quality of life, TIR above 70% and no nocturnal hypoglycemic arousals. Since there is a possibility of Schmidt syndrome, frequent monitoring of thyroid hormones is necessary.

Conclusions

Type 1 diabetes needs prompt recognition or periodical screening of potentially associated autoimmune conditions. Adrenal insufficiency even though rarely encountered among young patients, may be initially symptomless and characterized by slow progression until it turns into acute adrenal crisis, which represents a potentially life-threatening condition.

Keywords

adrenal insufficiency, type 1 diabetes, Schmidt syndrome.

JOINT2548

Management of hyperandrogenism in hemodialysis patient with PCOS: challenges and therapeutic strategies

Ghita Khamel[1], Meriem Bouzid[1], Kawtar Rifai[1], Fatima Toulali[1], Hind Iraqi[1] & Mohamed Hassan Gharbi[1]

[1]CHU Ibn Sina, Rabat, Morocco

Introduction

Polycystic ovary syndrome (PCOS) is the most common endocrinopathy affecting women of childbearing age. The mechanisms of this syndrome are due to hormonal imbalance, resulting in excessive production of androgens, particularly testosterone. this case report illustrates a case of renal failure at the hemodialysis stage with sopk.

Observation

31-year-old patient who has as antecedent: ESRD due to renal amyloidosis at hemodyal stage, cerebral venous thrombosis and IVC thrombosis on antic-oagulant of the antivitamin K family presented with moderate hirsutism evolving over the past 4 years, associated with rapidly worsening androgenic alopecia and cycle disorders. clinical examination reveals negative Homans sign, Absence of ancanthosis nigricans, a BMI of 21 kg/m^2 and a feriman score of 22. External genitalia examination: clitoral hypertrophy prader 1 Creatinine levels were 53 mg/hormonal investigation found Testosterone level =1 .45 ng/ml FSH =4.67 mu/ml LH=27 mu/ml 17 OH PROGESTERONE =1.5 ng/ml D4ANDROS-TENDIONE = 5.3 ng/ml SDHEA= 410 ng/ml negative ovarian tumour markers metabolic panel showed dylipidemia with normal glycated hemoglobin Surrenal MRI was normal, and pelvic MRI of enlarged ovaries with multiple follicular formations (greater than 12 follicles/ovary).

Discussion

The management of sopk in the context of end-stage renal failure and thrombosis antcd represents a challenge to the practitioner. Given the multiple contra-indications encountered with the usual treatments (oestroprogestogenic contra-ception, anti-androgenic progestins), therapeutic options will be directed towards 2nd-line treatments, notably spirinolactione, finasteride and flutamide. The data in the literature have demonstrated the possibility of using these treatments in this context, provided that the minimum effective doses are respected and regular monitoring of kalemia, INR and liver function is carried out. In safety studies concerning the use of mineralocorticoid receptor antagonists in hemodialysis patients, spirinolactone caused only a negligible change in baseline kalemia levels. In our patient, the choice of treatment was spironolactone at a dose of 50 mg/day, in in concession with the nephrologists.

Conclusion

The management of sopk in the context of ESRD and thrombosis antecedent remains a challenge for the practitioner, requiring a multidisciplinary approach involving specialists in endocrinology, nephrology and haematology.

Multiple endocrine and non-endocrine tumors in a patient with type 1 multiple endocrine neoplasia

Georgy Gabaidze[1], Margarita Perepelova[1], Elena Przhiyalkovskaya[1], Ekaterina Pigarova[1], Konstantin Slashchuk[1], Dmitry Beltsevich[1], Ekaterina Bondarenko[1] & Larisa Dzeranova[1]

[1]Endocrinology research centre, Moscow, Russian Federation

Introduction

Multiple endocrine neoplasia type 1 (MEN1) is a rare hereditary endocrinopathy with a prevalence of 1–9 cases per 100,000. It is characterized by the development of multiple endocrine and non-endocrine tumors, with the classical triad involving the parathyroid glands, pituitary gland, and duodenopancreatic neuroendocrine tumors (NETs).

Clinical Case Description

Since the age of 27, Patient M. experienced episodes of tremor and visual disturbances associated with fasting. At 37 years old, following recurrent renal colic episodes, kidney ultrasound revealed a left adrenal tumor. Further evaluation showed elevated prolactin levels (4,200 IU/ml; reference range: 63.6–349.8), and brain MRI confirmed the presence of a pituitary adenoma. One year later, the patient was started on cabergoline 0.5 mg twice weekly. Concurrently, laboratory tests showed increased parathyroid hormone (PTH) levels (26.2 pmol/l; reference range: 1.16–7.06), hypercalcemia (ionized calcium: 1.51 mmol/l; reference range: 1.10–1.30), and vitamin D deficiency (13.85 ng/ml) . Thyroid and parathyroid ultrasound revealed a thyroid nodule in the right lobe and a smaller hypoechoic lesion. Chest CT identified multiple rounded foci in both lungs. At age 39, prolactin levels remained elevated despite increasing the cabergoline dose to 1.5 mg weekly. MRI confirmed persistent pituitary adenoma, and the patient was diagnosed with primary hyperparathyroidism. Additionally, thyroid ultrasound revealed a 36×24×20 mm nodule in the right lobe, classified as EU-TIRADS 4. Fine-needle aspiration biopsy indicated a Bethesda IV lesion, while calcitonin levels were 6.6 pg/ml. Further investigations revealed multiple pancreatic NETs on abdominal CT and nodular adrenal hyperplasia in both glands. A 72-hour fasting test confirmed fasting hypoglycemia with elevated proinsulin levels. Chest CT showed multiple pulmonary foci (3–11 mm). Physical examination revealed numerous papillary skin formations on the torso, forearms, legs and feet, histologically established to be fibromas. The patient underwent thyroidectomy and parathyroidectomy, with histological analysis confirming follicular thyroid carcinoma in the right lobe and parathyroid hyperplasia. After completing radioactive iodine therapy, whole-genome sequencing identified a de novo MEN1 mutation. Three months later, the patient underwent partial resection of the right lower lung lobe. Immunohistochemical analysis confirmed a Grade 2 atypical pulmonary carcinoid. Consequently, combination therapy with capeci-tabine and temozolomide was initiated.

Conclusion

This case underscores the importance of comprehensive diagnostic evaluation in patients with MEN1. While the classical triad of tumors is well recognized, MEN1 patients may present with a broader spectrum of neoplasms, necessitating individualized and multidisciplinary treatment approaches.

Neurofibromatosis type 1 with polycystic liver disease and hypertension in the young as a co-occurrence with heterozygotic PKHD1 variant: a case report and review of the literature

Yotsapon Thewjitcharoen[1], Soontaree Nakasatien[1], Veekij Veerasomboonsin[2], Sandra Tsoi[3], Cadmon Lim[3] & Thep Himathongkam[1]

[1]Vimut-Theptarin Hospital, Theptarin Diabetes, Thyroid, and Endocrine Center, Bangkok, Thailand; [2]Vimut-Theptarin Hospital, Radiology, Bangkok, Thailand; [3]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong

Background
Neurofibromatosis type 1 (NF1) is a common genetic condition (estimated prevalence at 1:3000 live births) and 0.1-5.7% of patients with NF1 will develop pheochromocytomas and paragangliomas in their lifetime. However, other causes of hypertension (HT) in the young among these patients could be presented and polycystic liver disease is not a part of NF1 syndrome. While autosomal recessive polycystic kidney disease (ARPKD) caused by biallelic pathogenic variants in the polycystic kidney and hepatic disease 1 (*PKHD1*) gene are rare (estimated prevalence at 1:20,000 live births), the frequency of heterozygous carrier state of *PKHD1* gene is relatively common at 1 in 70 among general population. Polycystic liver disease had been described among patients with heterozygotic *PKHD1* variant. We herein report a rare case of an NF1 patient who presented with HT in the young and incidental finding of polycystic liver disease.
Case Report
A 37-year-old Thai patient with history of NF-1 (clinically diagnosed at the age of 20 from presence of café au lait spots and neurofibromas) consulted with HT in the young for 2 years without other symptoms. No family history of hypertension or other genetic disorders had been reported. Abdominal computed tomography revealed polycystic liver disease and a simple renal cyst with normal both adrenal glands. Laboratory studies showed normal results. Whole exome sequencing (WES) confirmed molecular diagnosis of NF1 with heterozygous pathogenic variants c.5268+1G>A of *NF1* and heterozygous pathogenic variants c.7594_7597del of *PKHD1* gene. Given the results of genetic testing and no identified other causes of HT, co-occurrence of NF1 and HT-associated heterozygotic *PKHD1* variant were diagnosed in this patient.
Conclusions
Our case highlights the diagnostic challenges of atypical phenotypes among individuals with NF1 might depend on the background of other genes. With increasing affordability of WES, its utility in uncovering the possibility of being affected by two inherited genetic conditions should be considered when findings are incompatible with the primary disease. The co-occurrence of *NF1* and *PKHD1* variants by chance or causative relationship should be further investigated in the future.

Association of diabetes mellitus, primary hypothyroidism, and addison's disease in a patient followed for glycogen storage disease type iii

Mohamed Bentraya[1], Najoua Lassoued[1], Houcem Elomma Mrabet[1], Zantour Baha[1], Alaya Wafa[1], Mariam Akacka[1] & Meryem Etteyeb[1]
[1]Taher Sfar University Hospital, Department of Endocrinology, Mahdia, Tunisia

Introduction
Glycogen Storage Disease Type III (GSD III) is a rare metabolic disorder characterized by hepatic and muscular glycogen storage defects, leading to liver dysfunction, cardiomyopathy, and metabolic complications. We report the case of a patient followed for GSD III who presented with diabetes mellitus, peripheral adrenal insufficiency, and primary hypothyroidism.
Case Presentation
A 41-year-old female patient was admitted to the hospital for an adrenal insufficiency crisis. She gives a complex medical history of GSD III, diagnosed at the age of 7, complicated by liver cirrhosis and hypertrophic cardiomyopathy with heart failure and epilepsy since infancy. At the age of 38, she was diagnosed with diabetes mellitus and peripheral hypothyroidism. She was under SGLT2 inhibitors, DPP-4 inhibitors, and L thyroxine. The diagnosis of primary adrenal insufficiency was retained. The patient was put on hydrocortisone and basal insulin. DPP4 inhibitors were stopped. Therapeutic education on the risk of hypoglycemia was done since the patient presented several factors precipitating hypoglycemia namely GSD III at the cirrhosis stage and adrenal insufficiency.
Conclusion
The overlapping metabolic and endocrine abnormalities in this patient highlight the necessity for a multidisciplinary management approach. This case underscores the importance of routine metabolic and endocrine evaluations in GSD III, particularly given the emerging associations with hypothyroidism and adrenal insufficiency. This case represents the first documented instance of both hypothyroidism and adrenal insufficiency in GSD III, highlighting the need for further research into endocrine dysfunction in the disease.

Primary hyperparathyroidism and autoimmune diseases: a case report

Nawres Bouaziz[1], Misbah Linda[1], Rachida Bouatay[1], Amal Chakroun[1], Mahdi Ferjaoui[1], Amel El Korbi[1], Nawres Kolsi[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]Fattouma Bourguiba University Hospital, Monastir, Tunisia

Introduction
Primary hyperparathyroidism (PHP) is the most common cause of hypercalcemia. Patients with autoimmune diseases can develop hypercalcemia but it is exceptionally due to PHP. The association of PHP withautoimmunedisordersis-describedveryrarely in the literatureso far. There are only few cases of immunemediatedhyperparathyroidism, associatedwith anti-calcium- sensingreceptorautoantibodies. The exact etiology of PHP in autoimuune diseasesis not known. The underlying pathophysiology was supposed to be either a common genetic predisposition or the extension of the autoimmune process to the parathyroid glands, which is still under debate. Our objective is to report a rare case associating a background of autoimmunity and primary hyperparathyroidism.
Observation
A 44-year-old woman with medical history of lupus, vitiligo, antiphospholipid antibody syndrome, GogerotSjogren's syndrome, arterial hypertension and dyslipidaemiawas referred to our department with primary hypercalcaemia in the face of bone pain with inflammatory arthralgia and functional impotence. Her biology showed a parathyroid hormone level of 121pg/l,a calcemia of 2.92 mmol/land a vitamin D level of 18 ng/ml. A cervical ultrasound and parathyroid MIBI scintigraphywere performed, showing a left inferior parathyroid nodule measuring 21*15*13mm. A left inferior parathyroidectomywas performed with anatomophatological findings of a parathyroid adenoma and a postoperative parathyroid hormone level of 19pg/land serum calcium of 2.3mmol/l.
Conclusion
Primary hyperparathyroidism and autoimmune diseases are two serious conditions. Their association is exceptional, but it can make their management more complicated. It is important for clinicians to remember that PHP is still the most common cause of hypercalcaemia. Therefore, when hypercalcaemia occurs in autoimmune diseases, it is prudent to carry out a full investigation to determine the most appropriate treatment to avoid potential complications.
Disclosure of interest
none declared.

Late diagnosis and course of the treatment of patient with pseudohypoparathyroidism type 1 A and growth hormone deficiency with excellent height outcome

Kateryna Kotlyarevska[1] & Susan Boyd[2]
[1]University of North Carolina, UNC Health Children's Novant Health, Wilmington, NC, United States; [2]University of North Carolina, UNC Health's Children's Wilmington, Wilmington, NC, United States

Background
Pseudohypoparathyroidism type 1A is a rare endocrine disorder in children due to mutations in GNAS gene. Typical presentations include hypocalcemia, hypothyroidism. Phenotypic characteristics (obesity, skeletal findings, short stature, developmental delay). Short stature with poor final adult height is a common presentation. Resistance to GHRH is described, there are cases of GH deficiency. GH has been used in the treatment of patients with PHP type 1A. There are no reports of combined use of GH and letrozole in patients with pseudohypoparathyroidism type 1A.
Objectives
To describe a rare case when a child was diagnosed with pseudohypoparathyroidism type 1 A later due to milder presentation, who was also later diagnosed with GH deficiency and had a great response to treatment with GH in conjunction with letrozole use.
Methods
A 4 years old male presented with obesity. Work up revealed mild hypothyroidism TSH=11.8 UIU/ml (reference 0.3-4.5), fT4=0.94 ng/ml (reference 0.89-1.7), negative thyroid antibodies. Newborn screen borderline for congenital hypothyroidism, patient was presumed to have mild form of congenital hypothyroidism, started on levothyroxine. At age 5 developed low calcium 8.3 mg/dl (reference 8.7- 10.4) with low 25 vitamin D, started vitamin D with improvement in calcium. At age 12 years calcium 6.7mg/dl, PTH =447 pg/ml (reference 18-88). Physical exam short 4th

metacarpals. Genetic testing confirmed GNAS gene mutation, patient was diagnosed with pseudohypoparathyroidism type 1A. Started calcitriol, calcium carbonate. Physical exam at age 12: Tanner III, advanced bone age. GH stim test peak of GH = 15 ng/ml. patient was not a candidate for GH therapy, started on letrozole. Growth velocity decreased, patient had another GH stim test with peak of GH = 4.1 ng/ml. Started GH therapy with increase in growth velocity from 3.6 cm/year to 8.8 cm/year.
Results
This is a case report of a child with PHP type 1A, whose diagnosis was delayed due to late presentation of hypocalcemia. Patient developed GH deficiency, treated with GH and aromatase inhibitor with great height outcome.
Conclusion
PHP type 1A is a rare disorder with multiple endocrine disorders related to hormonal resistance. Diagnosis can be delayed as hormonal problems may develop later in life. Earlier and fast progressing puberty happens in male patients with PHP type 1A, can worsen short stature. Testing for GH deficiency is important to reveal patients that can benefit from GH use. Combination of GH and aromatase inhibitor helps to improve final adult height in patients with PHP type 1A.

JOINT2236

Primary hypoparathyroidism and hashimoto's thyroiditis- a rare autoimmune disease combination

Tea Khurodze[1], vitali vashakidze[1], Basa Gegeshidze[1], Ana Pruidze[1] & Sopo Javelidze[1]
[1]David Tvildiani Medical University, Tbilisi, Georgia

Background
Primary Hypoparathyroidism is a rare disorder characterized by hypocalcemia and hyperphosphatemia resulting from inadequate PTH synthesis and secretion. Even though neck surgery is the most common etiology, the non-surgical forms have been linked to autoimmune dysregulation and activation of humoral or cell-mediated immunity against parathyroid cells. Hashimoto's thyroiditis, a common autoimmune cause of hypothyroidism. Both conditions can occur as an isolated endocrinopathy or as part of autoimmune polyglandular syndrome (APS), which is characterized by the functional impairment of multiple endocrine glands. Their coexistence is exceedingly rare but may suggest shared genetic and autoimmune mechanisms.
Case presentation
A 35-year-old Caucasian female was referred to the clinic with typical symptoms and complaints of hypocalcemia. For the past several years, patient had multiple hospitalizations due to episodes of hypocalcemia with tetany and seizures, requiring calcium infusions. Her medical history was remarkable for infertility with diminished ovarian reserve. The patient denied any history of neck surgery or irradiation. Regarding her family history, there was no evidence of cancer or genetic disorders among first-degree relatives. However, her father had type 2 diabetes. On Physical examination Trousseau's and Chvosteck's signs were positive. Laboratory studies revealed Primary Hypoparathyroidism with severe hypocalcemia—0.4mmol/l,low PTH levels – 2.64 pg/ml, high phosphorus—1.8 mmol/l,hypomagnesemia—0.63mmol/land low levels of Vitamin D-1,25—13ng/l. An electrocardiogram showed a prolonged QT interval. Brain MRI revealed no abnormalities. Infertility workup showed decreased ovarian reserve: AMH-0.527ng/ml FSH -14mIU/ml. transvaginal ultrasonography revealed low AFC. Combined calcium and calcitriol supplementation was commenced, with laboratory and clinical improvement. Assisted reproductive technology (ART) was used to aid in achieving pregnancy without success. The patient discontinued yearly checkups, and two years later, she was referred to an endocrinologist after a spontaneous pregnancy miscarriage. Laboratory tests revealed Hashimoto's subclinical hypothyroidism (TSH – 4.94mIU/ml; FT4-14.53pmol/l; ANTI-TPO – 221U/ml; ANTI-TG—1068 U/ml) and mild hypocalcemia due to irregular calcium supplement intake (Calcium – 1.02 mmol/L). Thyroid ultrasound showed an enlarged, heterogeneous thyroid (30cc) with hypoechoic nodules. Treatment with levothyroxine, calcium and calcitriol with lifestyle modifications resulted in symptom resolution. After several months of achieving laboratory and clinical improvement, infertility treatment is scheduled.
Conclusion
The coexistence of Primary hypoparathyroidism, Hashimoto's thyroiditis, and diminished ovarian function is exceedingly rare, but suggests a potential shared autoimmune pathogenesis. Further research is needed to explore possible genetic and immunological links. Since disease is lifelong, essential follow-up is needed to avoid complications and recurrence.

JOINT402

Beyond the triad: surgical management of endocrine and skeletal complications in mccune-albright syndrome

Sylwia Wolff[1], Adam Gałązka[1] & Marek Dedecjus[1]
[1]National Oncology Institute of Maria Sklodowska-Curie – National Research Institute, Department of Endocrine Oncology and Nuclear Medicine, Warsaw, Poland

Introduction
McCune-Albright Syndrome (MAS) is a rare, multisystem disorder arising from a post-zygotic activating mutation in the *GNAS* gene. This mutation leads to constitutive activation of the G protein α-subunit. The classic triad of MAS includes fibrous dysplasia, *café-au-lait* spots, and precocious puberty. This case report describes a 65-year-old woman with MAS, highlighting the complexity of managing this condition. It shows the critical role of a multidisciplinary approach, with a focus on surgical interventions and the use of translaryngeal ultrasound (TLUS).
Case Report
A 65-year-old woman presented with a history of MAS diagnosed in early adulthood. At the age of 61, she was diagnosed with hyperthyroidism. This necessitated a total thyroidectomy, which was performed as a staged procedure due to recurrent laryngeal nerve injury (RLN) during the initial right lobectomy. The left lobectomy was delayed until RLN recovered after close monitoring with TLUS. Mild hypercalcemia and neck ultrasonography led to the diagnosis of hyperparathyroidism, which was confirmed by fine-needle aspiration with positive PTH "washout", despite a negative MIBI scan. Surgical intervention included removal of a left lower parathyroid adenoma. Furthermore, the patient developed acromegaly, with elevated IGF-1 levels and characteristic clinical features. This prompted treatment with somatostatin analogues and ultimately two transsphenoidal pituitary surgeries. The procedures were technically challenging due to the presence of extensive fibrous dysplasia of the skull base. The cause of acromegaly was somatotroph hyperplasia involving the entire pituitary gland, with the presence of mammosomatotropic adenoma. The patient also experienced significant skeletal complications due to fibrous dysplasia, requiring multiple orthopedic surgeries.
Discussion
This case underlines the complexity of MAS. The patient showed a range of abnormalities that underscore the need for comprehensive evaluation and personalized treatment. It also presents the surgical challenges, emphasizing the need for careful planning and experienced surgeons. The staged thyroidectomy demonstrates the importance of careful consideration of potential complications, like RLN injury, and the use of tools like TLUS to guide surgical decision-making. Finally, this case reinforces the importance of a coordinated multidisciplinary approach involving different specialists to effectively manage the diverse manifestations of MAS.
Conclusion
This case report illustrates the complex and multifaceted nature of MAS. Surgical intervention plays a crucial role in managing this disorder. The integration of advanced imaging techniques, such as TLUS, can enhance surgical safety and efficacy. A multidisciplinary approach is essential for optimizing patient outcomes and improving the quality of life in individuals with MAS.

Effects of intensive iron chelation therapy on glucose abnormalities in beta-thalassemia major patients

Sohair Elsiddig[1], Ashraf Soliman[1], Fawzia Alyafei[1], Nada Alaaraj[1], Noor Hamed[1] & Shayma Ahmed[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Beta-thalassemia major is a transfusion-dependent condition characterized by chronic iron overload, leading to glucose abnormalities, endocrine dysfunctions, and impaired growth. This study evaluates the impact of intensive iron chelation therapy on these complications using real-world evidence from published literature.
Methods
A systematic review of 23 studies published between 2007 and 2023 involved 2,385 patients with beta-thalassemia major or intermedia. The studies assessed the effectiveness of iron chelation therapy using metrics such as serum ferritin, MRI-derived liver and pancreatic iron burden, glucose tolerance tests (OGTT), and endocrine outcomes.

Table 1. Real Impact Table from Big Table Data.

Outcome	Observed Change	Patients Impacted (% Real)	Comments
Glucose Abnormalities	Improvement in glucose tolerance	44%	Pancreatic T2* MRI outperformed serum ferritin in predicting improvements.
Insulin Sensitivity	Increased in patients with reduced liver/-pancreatic iron	68%	Strongly linked to early chelation therapy.
Hypogonadism	Reduction in prevalence	50%	Residual dysfunction remained in severe cases.
Growth Hormone Deficiency	Limited improvement in growth velocity	25%	Late diagnoses resulted in irreversible axis damage.
Linear Growth	Slight height catch-up	33%	Most effective in children receiving early therapy.
Delayed Puberty	Onset normalized	38%	Early chelation showed greater efficacy in mitigating pubertal delays.

Results
- Iron Chelation Therapy Impact:.
  - Glucose Abnormalities: Improvements were observed in 44% of patients with glucose tolerance abnormalities following intensive chelation therapy. Pancreatic T2* MRI proved superior to serum ferritin in predicting glucose abnormalities.
  - Insulin Sensitivity: Increased insulin sensitivity was reported in patients achieving reduced liver and pancreatic iron burden, with an estimated improvement in 68% of cases.
  - Endocrine Dysfunction:.
  - Hypogonadism: Prevalence was reduced in 50% of patients after chelation adjustments guided by pituitary MRI findings.
    - Growth Hormone Deficiency: Limited improvement in growth-velocity, with only 25% of patients showing significant catch-up growth due to irreversible damage in late-diagnosed cases.
    - Delayed Puberty: Onset normalized in 38% of patients, particularly in those who received early and aggressive therapy.
- MRI Utility: MRI assessments were consistently better at correlating iron burden with glucose and endocrine outcomes compared to serum ferritin. Pituitary and pancreatic iron deposition strongly predicted dysfunctions.
- Emerging Therapies: The data remains preliminary.

Conclusions
Intensive iron chelation therapy significantly improves glucose tolerance, insulin sensitivity, and some endocrine dysfunctions in beta-thalassemia major patients. However, limitations remain in reversing severe growth impairments. MRI is indispensable for accurate organ-specific iron monitoring and guiding treatment adjustments. The integration of advanced therapies, including gene therapy, may further enhance long-term outcomes.

Hereditary primary hyperparathyroidism is still challenging - beyond genetic screening

Diana Felicia Coles[1,2], Alina Sucaliuc[2] & Daniel Grigorie[2,3]
[1]"Carol Davila" University of Medicine and Pharmacy, Doctoral School, Bucharest, Romania; [2]"C.I Parhon" National Institute of Endocrinology, Bucharest, Romania; [3]"Carol Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Objective
Hereditary forms of primary hyperparathyroidism (PHPT) are much less common and often challenging the clinicians especially when active screening and genetic testing are lacking.
Methods
We report 4 members of a MEN 1 family identified from a Romanian cohort of 271 PHPT patients from a tertiary endocrinology center (4,5% had familial forms). Familial syndrome confirmation came after active screening despite long-standing history of PHPT and other associated endocrine tumors that were managed by different doctors never rising suspicion, along with low patient compliance. **Case 1:** 44 years old man (proband), with history of recurrent nephrolithiasis since age 26, PHPT first diagnosed at age 38 with total thyroidectomy and 2 glands parathyroidectomy (PTX), acromegaly (GH+PRL pituitary macroadenoma) at age 43, bilateral adrenal tumors with left adrenalectomy for Cushing syndrome at age 44 (8/5,8 cm); persistent mild HPTH, pancreatic tumors (gastrinemia 5900 pg/ml), right stable adrenal tumor (3/2 cm) at age 48; he denied surgeries, was frequently lost to follow-up and eventually died from right metastatic adrenocortical carcinoma (ACC). **Case 2**: 41 years old brother, diagnosed with PHPT multiglandular disease (hypercalcemia since age 37; range 11,2-12,4 mg/dl, no nephrolithiasis), biochemically cured by 3 glands and ½ PTX. Other tumoral findings: non-functional pituitary macroadenoma with hypogonadotropic hypogonadism, gastrinoma with Zollinger-Ellison syndrome (gastrinemia 56.050 pg/ml, medically controlled), multiple non-functional pancreatic tumors, bilateral non-functional adrenal tumors. **Case 3:** 72 years old father diagnosed with PHPT multiglandular disease (history of nephrolithiasis since age 30, PHPT with right inferior PTX at age 43, persistence of hypercalcemia since age 51 (range 10-12,5 mg/dl), bisphosphonates treated osteoporosis since age 70, persistent PHPT confirmation at age 72. PTX (2 and ½ glands) with auto transplant was performed. Other tumoral findings: pituitary incidentaloma, pancreatic non-functional uncinate tumor (2,3 cm), bilateral non-functional adrenal tumors, subcutanuous lipomas. **Case 4:** 20 years old daughter of case 2, was identified by screening with prolactinoma at age 9 and PHPT at age 19.
Discussion
HPTH persistence was the rule in this family with late MEN 1 diagnosis (decades). Clinical and hormonal screening was rewarding as the proband's brother and his daughter were diagnosed and treated adequately. Bilateral adrenal tumours were seen in 3 cases; Cushing syndrome and ACC are rare events in MEN 1.
Conclusions
Clinical and hormonal screening is fast and accessible allowing early diagnosis and adequate management of the patients and the other family members, even when genetics is not available.

Surgical management, diagnostic challenges, and long-term outcomes in a patient with MEN1: a unique case report

Ilana Katsobashvili[1], Laura Ebanoidze[1], Mariia Berlovich[1], Ekaterina Pigarova[1], Dmitry Beltsevich[1], Larisa Dzeranova[1] & Lydmila Ibragimova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a rare autosomal dominant disorder characterized by tumors of the parathyroid glands (PTG), pancreas, and anterior pituitary. Surgical management is often required, but long-term complications can be severe. Here, we present a unique case of a young patient with MEN1 and recurrent primary hyperparathyroidism (PHPT), who underwent total pancreatectomy, leading to diabetes mellitus (DM).
Clinical Case
A 27-year-old woman was diagnosed with MEN1 syndrome (heterozygous *c.203delC p.T70fsX118* mutation) following the incidental discovery of a pancreatic mass during an abdominal ultrasound. In 2012, she underwent resection of the right adrenal gland and cholecystectomy, along with total duodenopancreatectomy for multiple pancreatic tumors, which were histologically confirmed as somatostatinomas. As a result, she developed fulminant diabetes, necessitating intensive insulin therapy. In 2013, at the Endocrinology Research Centre, she underwent paraadenomectomy of four hyperplastic PTGs with autotransplantation of parathyroid fragments into the right forearm due to symptomatic PHPT. However, despite surgery, PTH levels remained persistently high. A modified Casanova confirmed high PTH production recurrence at the site of autotransplantat but with "hypoparathyroid" dependance on 2 mg of alfacalcidiol and 1000 mg of calcium consistent with immunoactive but inactive PTH circulation. After three years of calcium and alfacalcidol therapy, PTH levels was 84 pg/ml (non autotransplanted arm), with corrected calcium at 2.58 mmol/l(2.15–2.55) and normocalciuria. Given the continued elevation of PTH and calcium, further diagnostic workup was undertaken. Ultrasound revealed hyperplasia of the autotransplanted PTG fragments in the right forearm muscle. A repeat Casanova test confirmed recurrent PHPT, prompting autograft removal, which resulted in PTH decrease (8.3 pg/ml) and reintroduction of "hypoparathyroid" state. Additionally, brain MRI identified a 2.3 × 4.4 mm pituitary adenoma. Two years later, the patient was diagnosed with hyperprolactinemia, with stable adenoma size, and was prescribed cabergoline. In 2020, due to worsening glycemic control (HbA1c 7.5%), she was transitioned to insulin pump therapy, leading to stabilization within individual target ranges. Screening for diabetic complications revealed diabetic distal polyneuropathy. Currently, the

patient exhibits positive clinical outcomes, including PHPT remission and optimized glycemic control.
Results
This case highlights the complexities of identifying the primary source of PTH secretion in patients with autotransplanted PTG fragments, the risks associated with repeated surgeries, and the challenges of achieving glycemic stability in absolute insulin deficiency.

Multiple endocrine neoplasia type 1 phenotype with negative genetics

Nassim Ben Hadj Slama[1], Imen Halloul[1], Wiem Saafi[1], Ach Taieb[1], Hamza Elfekih[1], Ghada Saad[1] & Yosra Hasni[1]
[1]Farhat Hached University Hospital, Endocrinology, Sousse, Tunisia

Introduction
Multiple endocrine neoplasia are rare, with a prevalence of 1 in 200,000 in the general population. The diagnosis is confirmed by identifying a genetic mutation. However, in sporadic cases, this mutation remains undetected.
Case Report
We report the case of a 74-year-old female patient with a family history of papillary thyroid carcinoma in her daughter. She has been followed in our department for 10 years due to recurrent primary hyperparathyroidism. She underwent three surgical interventions for primary hyperparathyroidism over a 10-year period, each time revealing a parathyroid adenoma. This condition was complicated by osteoporosis. Suspicion of multiple endocrine neoplasia (MEN) prompted further investigations: Bilateral adrenal nodular thickening was observed. Hormonal evaluation of these nodules revealed ACTH-independent Cushing's syndrome. Pituitary imaging identified a 7 mm left-sided, non-secreting pituitary microadenoma. Genetic analysis for MEN1, AIP, CDKNIB, CaR, CDC73, and GNA11 was negative. The patient was started on calcimimetics for her primary hyperparathyroidism. Medical treatment is planned for her ACTH-independent Cushing's syndrome.
Discussion
The association of primary hyperparathyroidism, bilateral adrenal adenomas with ACTH-independent Cushing's syndrome, and a pituitary microadenoma supports the diagnosis of multiple endocrine neoplasia type 1 (MEN1). However, genetic testing for MEN1 mutations was negative. Indeed, in 5-10% of MEN1 cases, no mutation is detected. In such instances, the simultaneous occurrence of endocrine tumors typically associated with MEN1 mutations may result in a phenocopy. Other genetic mutations could be responsible for a MEN1-like phenotype, such as CDKN1B mutations, which cause multiple endocrine neoplasia type 4. Additionally, mutations in CaSR, AIP, and CDC73 have been implicated in MEN1-like syndromes. However, genetic testing for all these genes in our patient was negative. This case could represent a MEN1-like phenotype due to an unidentified etiology or the coincidental occurrence of multiple endocrine tumors.

Clinical case report: rare association of MEN2B syndrome and type 1 diabetes

Catarina Isabel Lopes[1], Miguel António Duarte[1], Marta Vaz Lopes[1], Mariana de Grine Severino[1], José Vicente Rocha[1,2], Carolina Peixe[1,2], Mariana Lopes-Pinto[1], Ana Gomes[1,2], Maria Inês Alexandre[1,2] & Ema Lacerda Nobre[1,2]
[1]Serviço de Endocrinologia, Diabetes e Metabolismo, Hospital de Santa Maria, ULS Santa Maria, Lisbon, Portugal; [2]Clínica Universitária de Endocrinologia, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

Multiple Endocrine Neoplasia type 2B (MEN2B) is a rare autosomal dominant disease caused by mutations in the RET proto-oncogene. It is associated with medullary thyroid cancer (MTC) and pheochromocytoma, along with systemic manifestations, including marfanoid habitus, mucosal neuromas, and gastrointestinal ganglioneuromatosis. We present a case of a 33-year-old man with uncontrolled hypertension, sinus tachycardia, hyperhidrosis, and marfanoid habitus. He was diagnosed with bilateral pheochromocytoma and subsequently MTC. Genetic testing confirmed a heterozygous RET mutation (pMet918Thr, exon 16), consistent with MEN2B. He underwent bilateral adrenalectomy, with pathology confirming benign pheochromocytomas. Later that year, he had surgery for MTC with lymph node metastases (total thyroidectomy with bilateral central and lateral neck lymph node dissection). Despite treatment, he remains with persistent disease, with a calcitonin doubling time of 36 months. He is now under replacement therapy with hydrocortisone (20 + 10 mg/day), fludrocortisone (0.1 mg/day), and levothyroxine (125 mg/day). The patient exhibits marfanoid features, including tall stature, pectus excavatum, arachnodactyly, and scoliosis. Additionally, he presents mucosal neuromas of the tongue and lips. Ocular complications have arisen due to absent tear production, leading to severe corneal ulceration. His gastrointestinal history includes intestinal ganglioneuromatosis, with surgeries at the age of 9 and 30 for bowel obstruction and perforated diverticulitis with peritonitis, respectively. He also has valvular heart disease, manifesting as mitral and tricuspid valve prolapse. Of particular interest is the onset of type 1 diabetes at the age of 34, one year after the MEN2B diagnosis. He is managed with multiple daily insulin injections (degludec and aspart), but his glycemic control remains suboptimal (HbA1c 10%). While secondary diabetes is common in patients with pheochromocytoma due to excessive catecholamine secretion, the coexistence of type 1 diabetes in MEN2B is extremely rare, with very few cases documented in the literature. This case illustrates the complexity of MEN2B, with its combination of neuroendocrine tumors and extensive multisystemic involvement. The unique coexistence of type 1 diabetes adds complexity to the patient's care, highlighting the need for ongoing research to explore any potential connections between MEN2B and autoimmune dysregulation. Multidisciplinary care is essential for managing the diverse complications of this rare syndrome.

The "4 A" syndrome: a rare etiology of adrenal insufficiency in pediatric endocrinology: about a case report

Meryam Alahyane[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Mohammed VI University Hospital, Marrakesh, Morocco

Introduction and Background
Allgrove syndrome, also known as "4A syndrome," is a rare autosomal recessive condition characterized by Alacrimia, Achalasia, Adrenal insufficiency, and Autonomic disturbances, among other features.
Case Report
We present the case of a 19-year-old female, born to consanguineous parents, who first exhibited symptoms at age 3 with alacrimia, initially mistaken for an allergic reaction. At 12, she presented with acute gastrointestinal symptoms, generalized hyperpigmentation, hypotension, and growth delays. Hormonal testing confirmed primary adrenal insufficiency (cortisol: 4.5 µg/dl, ACTH: 344 ng/L), and she was treated with hydrocortisone. Etiological investigations revealed a positive Schirmer's test, confirming alacrimia, and she was started on artificial tears. Achalasia was diagnosed via esophagram, showing impaired cardia motility, and treated with Heller's myotomy at age 14, leading to good progress. By 16, the patient developed polyradiculoneuropathy, confirmed by EMG findings of sensory and motor demyelination with axonal damage. Treatment with pregabalin, alpha-lipoic acid, acetyl-L-carnitine, and coenzyme Q10 yielded satisfactory results. However, she continues to experience severe learning difficulties. The clinical presentation strongly suggests Allgrove syndrome despite the absence of genetic confirmation.
Discussion
Allgrove syndrome is marked by adrenal insufficiency, alacrimia, and achalasia, often accompanied by progressive neurological impairments. Mutations in the **AAAS gene** on chromosome 12q13 are implicated. Alacrimia, the earliest and most constant sign, results from cholinergic innervation degeneration. Achalasia occurs in 75% of cases due to absent ganglion cells in the lower esophagus. Adrenal insufficiency, predominantly glucocorticoid defect due to ACTH resistance typically emerges early in life, with mineralocorticoid involvement in 15% of cases. Neurological manifestations include motor neuropathy, amyotrophy, and, rarely, amyotrophic lateral sclerosis or epilepsy.
Conclusion
Early diagnosis and a multidisciplinary approach are critical for managing Allgrove syndrome. Regular monitoring, steroid dose adjustments, and patient education are essential for improving outcomes.

Prader-willi syndrome: a 17-year retrospective study on clinical features and genetic findings

Sana Kmiha[1], Yassmine Mkhinini[1], Mariem Ammar[1], Rim Belhadj[1], Fatma Charfi[1], Salma Ben Ameur[1], Imen Chabchoub[1], Hajer Aloulou[1], Hassen Kammoun[2] & Thouraya Kammoun[1]
[1]Hedi Chaker University Hospital, Department of Pediatrics A, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Genetic Department, Sfax, Tunisia

Introduction
Prader-Willi syndrome (PWS) is a genetic disorder that exemplifies parental imprinting. It is a complex multisystemic condition with age-dependent phenotypic variability.
Methods
We conducted a descriptive, retrospective study of patients diagnosed with PWS and followed in the Department of Pediatrics A at Hedi Chaker University Hospital over a 17-year period (2008–2024).
Results
Eight patients, ranging in age from birth to 11 years, were included. Seven out of eight presented with dysmorphic features. Neonatal hypotonia was observed in five cases. Delayed motor development was noted in seven patients, and behavioral characteristics typical of PWS were reported in two children. A documented transition between nutritional phases was observed in one patient, while obesity was present in five cases. Endocrine disorders were identified in five patients, with hypogonadism in all of them, including cryptorchidism (5 cases), scrotal hypoplasia (2 cases), and micropenis (3 cases). Adrenal insufficiency was reported in one case, and diabetes in another. Additionally, one patient had epilepsy, and skeletal abnormalities, such as bilateral hip dysplasia, were observed in another. FISH analysis confirmed a deletion at the SNRPN locus in one patient. Methylation studies established the diagnosis in six patients, and whole-exome sequencing identified the condition in one case. Maternal uniparental disomy was detected in one patient, who also had homogeneous Klinefelter syndrome. All patients received multidisciplinary care. Growth hormone therapy was initiated in one patient, with ongoing monitoring. Unfortunately, one patient died due to respiratory failure.
Conclusion
Prader-Willi syndrome is a rare genetic disorder with potentially severe multisystemic complications. This study underscores the critical importance of early diagnosis and a tailored, multidisciplinary management approach.

JOINT1487

Congenital hyperinsulinism due to a heterozygous glud1 variant without hyperammonemia: a case report

Sandra Sanchez García[1], Karla Hernández Trejo[1], Leonor Hinojosa Amaya[1] & Vivian Morales Venegas[1]
[1]Universidad Autónoma de Nuevo León, Pediatria, Monterrey, Mexico.

Introduction
GLUD1 hyperinsulinism, also known as hyperinsulinism-hyperammonemia (HI/HA) syndrome, is a form of congenital hyperinsulinism caused by activating mutations in the GLUD1 gene, which encodes the enzyme glutamate dehydrogenase (GDH). This condition is characterized by recurrent episodes of hypoglycemia and mild, persistent hyperammonemia. Patients may also experience developmental delays and seizures, potentially due to increased GDH activity in the brain. The condition is typically inherited in an autosomal dominant manner, although de novo mutations can occur. Diagnosis is often confirmed through genetic testing, revealing heterozygous mutations in the GLUD1 gene. Cases of *GLUD1*-related congenital hyperinsulinism without hyperammonemia have been reported, despite it being a key feature of the syndrome.
Case Presentation
A male infant, born to healthy non-consanguineous parents via elective cesarean at 38.4 weeks, APGAR score 9/9, birth weight 2800g (p10-25), length 50 cm (p75-90). Only initial stabilization steps were required. At 30 hours of life, the patient presented with cyanosis, diaphoresis, and hypoglycemia (36 mg/dl). Despite glucose supplementation, he developed a partial seizure, prompting further evaluation. Laboratory tests showed elevated ammonia (110) and insulin 24 uU/ml, leading to a diagnosis of congenital hyperinsulinism after ruling out fatty acid oxidation disorders. On physical examination, the patient had no dysmorphic features. Consultations with the genetics and endocrinology departments were requested, and the diagnostic approach was initiated for hypoketotic hypoglycemia. Congenital hyperinsulinism was considered the primary diagnosis, with fatty acid oxidation disorder as a differential diagnosis. An expanded metabolic screening was performed, which was reported as normal, leading to the final diagnosis of congenital hyperinsulinism. He was treated with octreotide and glucose without significant clinical improvement until diazoxide was initiated. Diazoxide was then gradually tapered and discontinued by the age of one year. Genetic testing (WES with CNV analysis) identified a GLUD1 heterozygous variant of uncertain significance (VUS) as rs750420022, potentially linked to hyperinsulinism-hyperammonemia syndrome, which follows an autosomal dominant inheritance pattern. However, the variant was also found in the asymptomatic mother, reducing its clinical significance. The final diagnosis was Transient Congenital Hyperinsulinism.
Final Comments: Although hyperammonemia is a common feature of the HI/HA syndrome, it is not universal in all cases of GLUD1 mutations. Phenotypic variability may be due to the specific nature of the GLUD1 gene mutation, highlighting the importance of genetic analysis for the differential diagnosis of patients with hyperinsulinism, even in the absence of hyperammonemia. Early diagnosis and treatment are crucial to preventing long-term neurological complications.

Endocrinology and immunology: exploring their intersection in autoimmune disorders

Husham Bayazed[1,2]
[1]University of Zakho, Biomedical Science, Zakho, Iraq; [2]College of Medicine University of Zakho, Biomedical Science, Zakho, Iraq.

Background and Aims
The relationship between the endocrine and immune systems is increasingly recognized as a complex and significant intersection. Many endocrine glands are susceptible to autoimmune diseases, which often present at a young age and have a high prevalence in the population. This presentation aims to explore the origins of autoimmune processes in endocrine disorders, investigate the mechanisms behind immune system dysfunction, and identify potential therapeutic targets for intervention.
Methods
A comprehensive literature review was conducted based on recommendations and guidelines related to "Endocrinology and Immunology." Published studies were retrieved from PubMed, Elsevier, Wiley Online Library, Google Scholar, and Web of Science. The review included clinical trials and articles available in English.
Results
Recent studies highlight the critical role of endocrine hormones in regulating all biological processes throughout life. The secretion of these hormones must remain continuous and balanced; any disruption can lead to the formation of mutant proteins and auto-antigens. The immune system employs a surveillance mechanism where autoreactive T cells target and remove these abnormal proteins and tissue fragments to maintain homeostasis. The detection of autoantibodies serves as a surrogate marker for autoimmune endocrine disorders, and screening for these autoantibodies can help identify individuals at risk at an early stage. Disruption of immune homeostasis and immune surveillance mechanisms predisposes individuals to autoimmune endocrine disorders.
Conclusions
Autoimmune endocrine disorders are increasingly recognized as a consequence of the fragility of the immune surveillance system. Understanding these autoimmune mechanisms is crucial for the development of new targeted therapies that go beyond hormone replacement treatments. Early identification of individuals at risk is essential for restoring immune homeostasis before the onset of autoimmune disease.
Keywords
Endocrine disease, Autoimmunity, Targeted therapies, Immune surveillance, Autoantibodies.

A case history of prader-willi syndrome: 20 years observation period

Veranika Labashova[1], Elena Kuzmenkova[1], Anzhela Potash[1] & Natalia Okulevich[1]
[1]Republic Centre of Medical Rehabilitation and Balneotherapy, endocrinologic, Minsk, Belarus

Backgroud
Prader–Willi syndrome (PWS) is a rare disorder due to the absent expression of paternally active genes in chromosome 15. The mutation results in altered hypothalamus development and function, which impairs satiety, numerous hormonal deficits, changes in slee microstructure and other comorbidities.
Aims
We report a case of Prader-Willi syndrome over a period of 22 years between 2002 and 2024.
Case history
The first visit to the endocrinologist was on the second year of patienìs life. Both testes were undescended. Gonadotropin treatment was suggested but with no result, so orchiopexy of undescended testes was performed at the age of 3. Since early childhood patient had excessive weight that gradually increased, insatiable appetite, facial features of Prader–Willi syndrome that were confirmed by genetic analysis at the age of 8 (microdeletion 15q11-q13). He was treated by lifestyle intervention, his family was very motivated. And at the age of 14 he began to receive testosterone replacement for hypogonadism and small genitalia. At 24 years patienìs weight was 118 kg, height 170 cm, BMI 40 kg/m^2. At that time diabetes mellitus was diagnosed HbA1c 12.2%, C peptide 2,34 (0,367-1,47). During short period of basis-bolus insulin therapy his appetite remarkably increased and he gained 15 kg. Abdominal ultrasound imaging revieled nonspecific hepatomegaly. The therapy was changed to glyclasidi, metformin, basal insulin and glucagon-like peptide-1 (GLP-1). And a successful rapid weight reduction and decline of HbA1c 7.42% was received. The patient had normal thyroid status TSH 1.41 but decreased IGF–1 level 115,2 (130-295). Brain magnetic resonance imaging was unremarkable. Growth hormone therapy (GHT) is known to improve body composition, height and body mass index, improve cognitive function and long-term health-related quality of life. On the other hand literature represents the cases of patients with Prader-Willi syndrome worsening snoring during growth hormone therapy. And respiratory failure is the leading cause of mortality in individuals with PWS, making early diagnosis and the treatment of respiratory problems crucial for their survival. Our patient had demonstrated obstructive sleep apnea and excessive daytime sleepiness. Possible adverse effects of GHT on the respiratory system limited our ability of GHT implementation in patient.
Conclusion
Using consensus diagnostic criteria for PWS 1993, our patient fulfilled clinical diagnosis. Glucagon-like peptide-1 was effective in treating hyperphagia, weight reduction and as glucose lowering agent. Further investigations on GHT effect on the respiratory system is needed.

Hyperthyroidism and thrombosis of a varicocele: an unexpected linka case report

Abdejlil Barhoumi[1], Sana Abid[1], Ines Bayar[1], Kamar Ezzamene Mahmoud[1], Bilel Ben Amor[1], Ekram Hajji[1], Hela Marmouch[1], Hanene Sayadi[1] & Inès Khochteli[1]
[1]Fattouma Bourguiba University Hospital, Department of Internal Medicine and Endocrinology, Monastir, Tunisia

Introduction
Venous thromboembolic disease (VTE) is a multifactorial condition primarily associated with hypercoagulable states. Hyperthyroidism is one such condition, promoting a procoagulant state. We report a case of varicocele thrombosis associated with hyperthyroidism, with no other identified risk factors.
Case Report
A 48-year-old man with no significant medical history was followed in the endocrinology department for hyperthyroidism due to a Grave disease with multinodular goiter. Clinically, he presented with thyrotoxicosis syndrome without an obvious goiter or exophthalmos. Laboratory tests revealed a TSH level of 0.01 mIU/land FT4 at 29.5 pmol/l,with positive TSH receptor antibodies. He was started on antithyroid therapy, followed by definitive treatment with radioactive iodine. Inflammatory markers and hemostasis tests were within normal ranges. Additionally, the patient experienced testicular pain with a sensation of heaviness. A scrotal ultrasound revealed left varicocele thrombosis. He was treated with analgesics and oral anticoagulants, leading to a favorable clinical and biological outcome.
Discussion
Hyperthyroidism induces a hypercoagulable state, promoting a prothrombotic condition and increasing the risk of VTE disease. Varicocele thrombosis is a rare cause of testicular pain. Other reported etiologies include trauma, obstruction of venous drainage by malignant tumors, genital and/or inguinal infections, and coagulation disorders.
Conclusion
Hyperthyroidism can be considered a risk factor for thrombosis, implying that it should be discussed as a probable etiology, especially in the presence of other clinical elements.

Neuromyelitis optica and endocrine comorbidities: a case report

Yassmine Abdelkafi[1], Khouloud Boujelben[1], Mouna Elleuch[1], Nada Hassairi[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Neuromyelitis optica (NMO) is a rare, inflammatory, autoimmune demyelinating disease of the central nervous system (CNS), primarily affecting the optic nerves and spinal cord. The presence of anti-aquaporin-4 (AQP4) antibodies plays a key role in its pathogenesis. Given the high expression of AQP4 in the hypothalamus and other endocrine-related regions, NMO is frequently associated with endocrine dysfunctions, particularly autoimmune thyroid disorders. This case highlights the intersection between NMO and endocrine comorbidities.
Observation
We report the case of a 50-year-old woman with a one-year history of NMO, initially presenting with ophthalmoplegia and progressive bilateral visual impairment. She was treated with plasmapheresis, high-dose corticosteroids, and azathioprine. Eleven months later, she was referred for the evaluation of an incidental thyroid nodule and signs suggestive of thyroid dysfunction. Laboratory investigations revealed positive anti-thyroid peroxidase (TPO) and anti-thyroglobulin (TG) antibodies, confirming Hashimoto's thyroiditis. Clinical examination showed a palpable, heterogeneous thyroid gland, euthyroidism, and persistent asthenia. Further endocrine evaluation ruled out adrenal insufficiency and diabetes insipidus.
Discussion and Conclusion
Autoimmune thyroid disease, including Hashimoto's thyroiditis and Graves' disease, is the most frequently reported endocrine comorbidity in NMO. The detection of AQP4 in thyroid follicular cells suggests a potential pathogenic link. Studies indicate that up to 40% of NMO patients may have concurrent autoimmune disorders. Moreover, recent research suggests that the presence of anti-TPO antibodies may correlate with increased severity of myelitis in NMO. Patients with elevated anti-TPO levels tend to have higher disability scores on the Expanded Disability Status Scale (EDSS), a greater number of spinal cord lesions, and more frequent longitudinally extensive transverse myelitis (LETM). This association could be explained by a more aggressive immune response or by the role of thyroid hormones in myelin repair. In addition, hypothalamic involvement in NMO, although rare (reported in 2.5%–3% of cases), can be highly specific and pathognomonic due to the strong expression of AQP4 in this region. Hypothalamic lesions may manifest as isolated clinical features, including dysautonomia, hypersomnia, metabolic disturbances, and endocrine dysfunctions such as central adrenal insufficiency and the syndrome of inappropriate antidiuretic hormone secretion (SIADH). SIADH results from impaired osmoregulation due to astrocytic damage in the hypothalamus, leading to hyponatremia and altered fluid balance. Given these associations, a systematic endocrine assessment is recommended in NMO patients to optimize management and improve long-term outcomes.

Assessment of bone health, psychological wellbeing and clinical spectrum in turner syndrome: experience from a tertiary healthcare centre from north india

Siddhnath Sudhanshu[1,2], Umesh Sah[2], Amita Moirangthem[2], Vijayalakshmi Bhatia[2] & Preeti Dabadghao[2]
[1]All India Institute of Medical Sciences, Patna, Additional Professor, Patna, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Background
Turner's syndrome (TS) presents with diverse clinical manifestations. The patients with TS are predisposed to develop osteopenia, osteoporosis and fractures owing to low bone mineral density (BMD). Prevention strategies and screening for poor bone health and psychological health should be initiated early in the course of disease to prevent further complications.
Objectives
To assess the clinical spectrum in patients with TS including the assessment of bone health and psychological wellbeing for which there is a paucity of data in the literature.
Methods
A cross-sectional observational study from a tertiary healthcare centre from north India. Karyotype proven TS (n: 67) attending the endocrinology outpatient department were included. All the subjects were evaluated for anthropometry, detailed records of clinical features and detailed physical examination. Areal BMD (L1-L4) estimation and the Z-score using HOLOGIC-DXA machine were performed in all patients. Psychological assessment was done using GAD7 (Anxiety) and PHQ9 (Depression) questionnaire for participant age $\geq$11 years.
Results
The most common karyotype found was 45X (54%) followed by 45Xi; Xq (13%). The median age of diagnosis was 15 years (4-27 years). Short stature (91%) and delayed puberty with primary amenorrhea (82%) were the predominant presenting complaints. The patients with menarche or HRT $>$2 years had significantly higher mean BMAD [0.243 (0.03) vs. 0.21 (0.02) gm/cm^3; $P<0.05$] compared to prepubertal or patients with HRT for less than 2 years. The rate of mild to severe anxiety and depression in TS patients were significantly higher than that of healthy control (P value: <0.05) but not that of type 1 diabetic controls (p: >0.05).
Conclusions
Short stature & primary amenorrhea were the most common clinical presentation often leading to late diagnosis of Turner's syndrome. Bone mineral density was significantly lower in patients with delayed puberty or inappropriate HRT, which suggest that timely and appropriate estrogen therapy is necessary to maintain appropriate bone health. While assessing the BMD in participants with TS, adjustment for height and/or smaller bones due to short stature is necessary to avoid false interpretation. Anxiety and depression were often unnoticed but were present in a significant number of patients. We must include routine and regular assessment of psychological wellbeing in management protocol of TS for early detection and management of psychological disorder in subjects with TS.

Association of primary hyperparathyroidism and papillary thyroid carcinoma in a patient with brown tumor and parkinsonism

Sona Maghakyan[1], Sofiya Khachaturyan[1], Ashnak Hrantyan[1], Nairi Melkonyan[1], Andranik Aleksanyan[1,2] & Yelena Aghajanova[2,3]
[1]Mikaelyan University Hospital, Yerevan, Armenia; [2]Yerevan State Medical University, Yerevan, Armenia; [3]Muratsan University Hospital, Yerevan, Armenia

Primary hyperparathyroidism (PHPT) is an endocrine disorder characterized by increased parathyroid hormone secretion, leading to hypercalcemia and renal, gastrointestinal, neuromuscular, psychological and skeletal manifestations. We would like to introduce the non-common clinical manifestations of PHPT like Brown tumor and Parkinsonism.
Case report
A 64-year-old female was admitted to the Mikaelyan Institute of Surgery complaining of general weakness, pain in the right lumbar region and fever. The patient was diagnosed with Ureterolithiasis, right-ureteral stone obstruction, right-sided ureter hydronephrosis, and pyelonephritis and was preparing for surgery. A right-sided nephrectomy and right-sided ureterolithotomy were performed. In medical history: Schizophrenia for about 25 years, hemimaxillectomy for a giant cell tumor in the upper jaw 10 years ago. The patient has been on Haloperidol 10mg for more than 25 years and Trihexyphenidyl 2mg for the past 7 years. The patient exhibited reduced interaction during the initial examination and appeared very indifferent. Objective neurological examination revealed the following findings: combined rest and action tremor Tremor observed in the chin, accompanied by noticeable oral dyskinesias. Gait is characterized by wide-based steps with shuffling. The patient was diagnosed Drug-induced Parkinsonism. Blood tests: Hb-76g/l(N 115-152), Creatinine-128umol/l(44-100), Ca ionized-2.20mmol/l(1.13-1.32), PTH-409.6pg/ml (15-65), Vitamin D-10.6ng/ml (30-100), TSH-3.85 uIU/ml (0.3-4.5). Neck ultrasound: tissue formation in the left parathyroid gland and multiple thyroid nodules (TI-RADS 4). The patient refused to do FNA. Dual-energy X-ray absorption: T-score at L1-L4 -5.1, hip T-score -5.4. Full-Body CT Scan: multiple lytic lesions involving bones, probable Brown tumor. Esophagogastroduodenoscopy: atrophic gastritis. The patient started treatment with Vitamin D_3, rehydration and correction of anemia. After 1 month, she underwent left parathyroidectomy and total thyroidectomy. The histology showed parathyroid adenoma and papillary microcarcinoma of the left thyroid. PTH level decreased immediately after surgery (from 551.2 to 69.98). The patient's neurological condition also improved. After surgery the patient was given Vitamin D_3, Calcium gluconate and Levothyroxine. The patient is currently under the follow-up.
Conclusion
Approximately 90% of cases of hypercalcemia are caused by hyperparathyroidism or malignancy. Our patient had both. Except common manifestations of hypercalcemia and PHPT, the patient had also rare manifestations, such as brown tumor. It is a non-neoplastic, reactive bone lesion resulting from excessive PTH secretion. Hypercalcemia is known to cause neuropsychiatric dysfunction too. Evidence of hyperparathyroidism associated with parkinsonism is rare. In our patient parathyroidectomy provided a significant remission of parkinsonism. Therefore, in this case, Parkinsonism may not only be drug-induced, but also hypercalcemia-induced.

Factors influencing linear growth in children with beta-thalassemia major: a comprehensive review of studies (2000–2025)

Mohamed AlKuwari[1], Ashraf Soliman[1], Shayma Ahmed[1], Nada Alaaraj[1], Noor Hamed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Growth disorders are highly prevalent among children with beta-thalassemia major, affecting both height and weight. Chronic anemia, iron overload, and endocrine dysfunctions contribute to growth retardation, significantly impacting quality of life. Despite advancements in transfusion and chelation therapies, growth impairment remains a major complication in this population.
Objectives
To evaluate the key factors influencing linear growth in children with beta-thalassemia major, focusing on age, sex, serum ferritin levels, GH-IGF1 axis, liver iron concentration, and transfusion status, and to assess real predictors of growth outcomes.
Methods
This review includes 30 studies published between 2000 and 2025, encompassing 2,500 children and adolescents with beta-thalassemia major. Data on height, weight, serum ferritin, GH-IGF1 axis, liver iron burden, and transfusion status were analyzed for their impact on growth outcomes.
Results
- **Age and Sex:** Growth retardation was observed across all age groups, with increased severity during adolescence due to delayed puberty. No significant differences were noted between sexes in growth outcomes.
- **Serum Ferritin Levels:** Elevated ferritin ($>$2500 ng/ml) was inversely correlated with height and weight. High ferritin levels were associated with endocrine dysfunctions, including growth hormone (GH) deficiency and hypogonadism.
- **GH-IGF1 Axis:** GH deficiency and low IGF-1 levels were prevalent among patients with growth failure. Studies highlighted the significant role of the GH-IGF1 axis in predicting growth outcomes.
- **Liver Iron Concentration:** High liver iron burden ($>$7 mg/g dry weight) was negatively associated with linear growth due to its impact on endocrine glands and hepatic function.
- **Transfusion Status:** Regular transfusions maintaining pre-transfusion hemoglobin $>$9 g/dl improved growth outcomes, while inadequate transfusion schedules exacerbated growth delays.

• **Real Growth Prediction:** A combined analysis of these factors across studies demonstrates that real growth prediction is when accounting for regular transfusions, early chelation therapy, controlled ferritin levels, and optimization of the GH-IGF1 axis. Patients with these managed parameters showed a significantly higher likelihood of achieving normal growth trajectories compared to those with poorly managed conditions.

Discussion and Conclusions

This review highlights the multifactorial nature of growth impairment in children with beta-thalassemia major. Factors such as iron overload, GH-IGF1 axis dysfunction, and inadequate transfusion schedules are key contributors. Effective management strategies, including early chelation, regular transfusions, and endocrine evaluation, are critical for optimizing growth outcomes. Future research should focus on longitudinal studies to refine growth prediction models and explore novel therapeutic approaches. Clinicians should adopt a multidisciplinary approach to address the diverse challenges associated with growth disorders in this population.

The critical role of pituitary imaging in sickle cell disease: insights into growth and endocrine dysfunction

Ashraf Soliman[1], Shayma Ahmed[1], Carolin Beck[1], Nada Alaaraj[1], Noor Hamed[1], Abbas Noureldin[1] & Elsaid Bedair[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background

Pituitary imaging is vital for identifying structural and functional abnormalities contributing to endocrine dysfunction in sickle cell disease (SCD). Chronic hypoxia, iron overload, and microvascular damage often lead to growth hormone (GH) deficiencies, delayed puberty, and other complications. This review explores the role of imaging in diagnosing and managing these issues.

Objectives

1. To evaluate the diagnostic utility of imaging modalities, particularly MRI, in detecting pituitary abnormalities in SCD.
2. To investigate the relationship between structural pituitary changes and endocrine dysfunction.
3. To highlight the potential of advanced imaging biomarkers in risk stratification and monitoring.

Methods

A chronological review of studies from 1993 to 2024 was conducted, analyzing findings from MRI, CT, and advanced imaging techniques to assess their role in detecting pituitary abnormalities and associated endocrine dysfunctions in SCD patients.

Results

- Early studies identified empty sella and vascular insults linked to growth impairments (Broadbent *et al*., 1993; Soliman *et al*., 1995, 1997).
- MRI established itself as the gold standard for detecting pituitary siderosis, reduced gland size, and structural atrophy strongly associated with GH deficiency (Smiley *et al*., 2008; Vadivelan *et al*., 2024).
- Functional MRI revealed links between metabolic stress, reduced connectivity, and cognitive deficits (Fields *et al*., 2020). Blood-brain barrier disruptions further highlighted vascular-neuroendocrine interplay (Lin *et al*., 2021).
- Quantitative imaging biomarkers enhanced the understanding of hemodynamic and structural disruptions, aiding in early detection and monitoring of dysfunctions (Stotesbury *et al*., 2021).
- Animal models demonstrated white matter injury and astrocyte activation contributing to cognitive and motor dysfunctions, mirroring human findings (Hazra *et al*., 2023).
- Pituitary imaging findings such as iron deposition and structural abnormalities were directly associated with panhypopituitarism, delayed puberty, and hypothyroidism (Shekhar *et al*., 2021).

Conclusion

Pituitary imaging, especially MRI, is essential for diagnosing structural abnormalities and functional disruptions in SCD. Advances in biomarkers and quantitative techniques promise improved detection, monitoring, and personalized interventions to mitigate endocrine dysfunctions in SCD.

Keywords

Sickle Cell Disease, Pituitary Imaging, Endocrine Dysfunction, MRI, Growth Hormone Deficiency, Iron Overload, Biomarkers.

Impact of iron deficiency anemia on growth and endocrine functions: reversibility with treatment

Mohamed AlKuwari[1], Ashraf Soliman[1], Sohair Elsiddig[1], Nada Alaaraj[1], Noor Hamed[1], Fawzia Alyafei[1] & Noora AlHumaidi[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background

Iron deficiency anemia (IDA) is the most prevalent micronutrient deficiency globally, affecting over 40% of children under five years old, particularly in low- and middle-income countries. Beyond its hematological impact, IDA can disrupt endocrine functions, including growth, thyroid, pituitary, and adrenal systems. These disruptions contribute to growth retardation, hormonal imbalances, and altered metabolic homeostasis. This review synthesizes evidence from clinical and experimental studies to evaluate the effects of IDA on growth and endocrine functions and highlights the reversibility of these effects following iron therapy.

Objectives

To assess the impact of IDA on growth and endocrine functions (thyroid, pituitary, and adrenal) and to evaluate the effectiveness of treatment in reversing these impairments.

Methods

A systematic review of 12 studies published between 1990 and 2023 was conducted, including 567 patients with IDA and several experimental animal models. The studies were analyzed for the impact of IDA on growth velocity, IGF-I secretion, thyroid hormones, and adrenal reserve (ACTH and cortisol), and the reversibility of these effects with treatment.

Results

1. **Growth:** IDA significantly reduces growth velocity and IGF-I secretion. Among 567 patients across the studies, most exhibited impaired height-for-age z-scores and reduced BMI. Post-treatment, iron therapy restored growth velocity and improved IGF-I levels in all studies.
2. **Thyroid Function:** Mild hypothyroidism, characterized by reduced thyroid hormone secretion, was documented in 5 studies, accounting for 220 patients. Iron supplementation normalized thyroid hormone levels in all treated patients.
3. **Pituitary Function:** Suppressed GH and IGF-I secretion were reported in 6 studies, including 345 patients. Post-treatment normalization of GH and IGF-I secretion significantly improved growth and metabolic markers.
4. **Adrenal Function:** Reduced adrenal reserve (low ACTH and cortisol levels) was observed in severe IDA cases in 4 studies, involving 145 patients. Iron supplementation restored adrenal function, demonstrating reversibility with therapy.

Discussion

The review highlights the systemic impact of IDA on growth and multiple endocrine axes. The reversibility of these effects with iron therapy underscores the critical importance of early diagnosis and treatment. Thyroid and adrenal functions were particularly sensitive to IDA but improved significantly post-treatment. Growth markers such as IGF-I and BMI responded robustly, showcasing the critical link between iron availability and endocrine health.

Conclusions

IDA profoundly affects growth and endocrine functions, including thyroid, pituitary, and adrenal systems. Iron therapy effectively reverses these impairments, emphasizing the importance of timely intervention. Future research should explore long-term outcomes and optimize treatment strategies for IDA-related endocrine dysfunctions.

Graves disease of pubertal age associated with DIDMOAD (wolfram) syndrome

Anna Vardanyan[1], Yelena Aghajanova[1], Gayane Bayburdyan[1], Mikhayil Aznauryan[2], Lusine Arakelyan[1] & Lilit Mkrtchyan[1]
[1]Yerevan State Medical University, Endocrinolgy, Yerevan, Armenia; [2]Astghik MC, Ophtalmology, Yerevan, Armenia

Introduction

Graves disease is an autoimmune disease characterized by hyperthyroidism due to circulating thyroid-stimulating autoantibodies that bind to and activate thyrotropin receptors, causing the hyperplasia and hyperfunction of thyroid gland. The symptoms are wide ranging as thyroid hormone affects many body systems. The disease is common in people with age below than 40 and mainly in women. Graves disease is caused by a combination of genetic and environmental factors while genetics being the main cause. Genetic predisposition to Graves ‘

disease is caused by multiple genes. Wolfram Syndrome is a rare autosomal recessive progressive neurodegenerative disorder with estimated prevalence of 1 in 500,000 r, also known as DIDMOAD syndrome for its four most common features (Diabetes Insipidus, Diabetes Mellitus, Optic Atrophy, Deafness). Patients present with nonautoimmune and non-HLA linked diabetes mellitus associated with optic atrophy in the first decade, diabetes insipidus and sensorineural deafness in the second decade, renal tract abnormalities early in the third decade and multiple neurological abnormalities early in the fourth decade. In the literature available, we did not find a description of the combination of Graves' disease and DIDMOAD syndrome.
Case report
An 8 years old boy was diagnosed with type 1 diabetes with ketosis on presentation and treated with insulin. However, upon diabetes compensation polydipsia and polyuria continued and the following week diabetes insipidus was diagnosed. MRI of the brain was only significant for posterior arachnoid cyst 1.5x2.5x1.7 cm between the cerebellar hemispheres. Genetic analysis for Wolfram syndrome was not available at that time, therefore patient underwent annual optic nerve funduscopy, audiometry and ultrasound of the urinary tract. After 5 years, he developed hearing loss and early signs of macular atrophy, as well as ureteral dilation. Finally, genetic analysis was done abroad and WFS1 gene mutation was identified.
Conclusion
Apparently, this is one of the first descriptions of the combination of Graves disease and DIDMOAD syndrome in the world literature and definitely the first in Armenia. Taking into account that in some countries genetic analysis for Wolfran Syndrome may not be readily available, annual survey for all the components of the syndrome is recommended. This is especially important in atypical and fast progressing cases of Wolfram syndrome.

JOINT3520

Therapeutic difficulties in the treatment of a girl with primary hypoparathyroidism

Hanna Borysewicz-Sanczyk[1], Beata Sawicka[1], Justyna Michalak[1], Karolina Stożek[1] & Artur Bossowski[1]
[1]Medical University of Bialystok, Department of Pediatrics, Endocrinology, Diabetology with a Cardiology Divisions, Bialystok, Poland

Introduction
Primary hypoparathyroidism is a rare cause of persistent hypocalcaemia and hyperphosphataemia in children. It may occur either as a component of a genetic syndrome e.g. 22q Deletion (DiGeorge Syndrome) or autoimmune processes in the parathyroid glands. CASE PRESENTATION: We report a seventeen-year-old girl diagnosed with primary hypoparathyroidism at the age of ten, who initially presented severe hypocalcaemia with repeated seizures. The autoimmune hypoparathyroidism had been confirmed in the Department of Paediatrics, Endocrinology, Diabetology with Cardiology Divisions, Medical University of Białystok with low PTH concentration (<3pg/ml), typical biochemistry (total serum calcium concentration 0.8 mmol/l,plasma phosphate 4.1 mmol/l)and positive INF-omega antibodies. Other hormonal analyses showed no thyroid or adrenal disorders. Ultrasonography showed no parathyroid pathology. Long QTc (over 0.5 seconds) was present in the ECG. Hypocalcaemia was initially treated with intravenous and oral calcium, vitamin D_3 and vitamin D analogue - alfacalcidol. Sevelamer, a phosphate-binding drug was used for the management of hyperphosphataemia. Moreover the girl was given dietary recommendations to reduce phosphate in the diet. The patient was also treated with beta-blocker for LQTc syndrome. Although the calcium serum concentration increased initially, it remained below the normal reference range, and phosphate level remained over the norm despite the treatment. Other accompanying symptoms (intermittent fever, elevated CRP and radiological features of pneumonia and pericarditis) allowed the diagnosis of systemic lupus erythematosus (SLE) and the treatment with glucocorticoids was initiated, which improved parameters of calcium-phosphate balance. Further immunological examinations were negative for IL-22, IL-17A, IL-17F, IFN-lambda, IFN-alpha2A, and CaSR antibodies. Genetic diagnosis excluded AIRE and CaSR mutations. During first five years of therapy calcium concentrations persisted in the lower limit and phosphate concentration slightly above the norm with no clinical symptoms of electrolyte disorders. Attempts to increase oral calcium dosage resulted in a complication as nephrocalcinosis. After another two years of therapy the girl presented with hypocalcemia and hyperphosphatemia, that required the modification of the oral therapy. Her current daily calcium supplementation is 4 x 1000mg and phosphate-binding drug dosage is 4 x 800mg.
Conclusions
Although primary hypoparathyroidism is a rare endocrinopathy in children, it often causes therapeutic difficulties, as there is no standard hormone replacement therapy.

Atypical marfan syndrome (MFS) in a pediatric endocrinology practice

Alua Aldabergen[1], Marzhan Rakhimzhanova[1] & Ayazhan Abikenova[1]
[1]CF UMC, Astana, Kazakhstan

Introduction
Marfan syndrome (MFS) is a connective tissue disorder caused by mutations in the **FBN1** gene, typically affecting the cardiovascular, skeletal, and ocular systems. While diagnosis is usually made clinically, genetic testing is often required in atypical cases to confirm the diagnosis. This report presents a 12-year-old girl diagnosed with Marfan syndrome through genetic testing despite lacking classic cardiovascular and ocular symptoms typically associated with the condition.
Case report
The patient was referred for evaluation due to accelerated growth to the endocrinologist. She also reported fatigue, shortness of breath on exertion, and frequent urination. The patient was born from a first pregnancy. She had a sibling who passed away the day after birth, the father does not recall the cause of death. This family history raises the possibility of a hereditary condition. On examination, she had a tall, thin body, long fingers (**arachnodactyly**), and pectus carinatum, scoliosis, pectus carinatum, joint hypermobility, and stretch marks. However, she did not exhibit cardiovascular or ocular symptoms, such as aortic dilation or lens dislocation, which are classically associated with Marfan syndrome. Echocardiography: normal heart function with no evidence of aortic root dilation, though an incidental **mitral annular ring** was noted. Her ophthalmologic examination was normal. Genetic testing identified a **heterozygous pathogenic variant in the FBN1 gene (c.4930C > T, p.Arg1644Ter)**, confirming Marfan syndrome. This nonsense mutation results in a truncated **fibrillin-1** protein, which plays a crucial role in connective tissue integrity. The variant is classified as **pathogenic (ClinVar ID: VCV000200186)**, with a likely **de novo** inheritance, though parental testing is recommended.
Discussion
This case highlights the variability in Marfan syndrome presentation, particularly in patients without significant cardiovascular or ocular involvement. Despite the absence of aortic dilation or lens dislocation, skeletal features such as scoliosis and pectus carinatum were consistent with the diagnosis. **Genetic confirmation of the FBN1 mutation was essential**, as clinical criteria alone may not have been sufficient for diagnosis. Although the patient does not currently exhibit life-threatening cardiovascular complications, **regular monitoring** is crucial, as these issues may develop over time. Marfan syndrome is a progressive condition, and **aortic dilation, mitral valve prolapse, and lens dislocation can emerge later in life**.
Conclusion
Although the patient currently lacks cardiovascular and ocular abnormalities, **ongoing surveillance and multidisciplinary care** are essential to managing long-term risks. Regular cardiovascular, ophthalmologic, and orthopedic monitoring, along with **genetic counseling**, will be key in ensuring early detection and intervention for potential complications.

POEMS sy-a rare etiology of endocrinopathy

Marija Miletic[1], Milina Tancic Gajic[1], Milos Stojanovic[1], Milica Jovanovic[1], Zorana Arizanovic[1], Natalija Pavlovic[1], Taisa Bojovic[1] & Svetlana Vujovic[1]
[1]University Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Medical Faculty University of Belgrade, Belgrade, Serbia

Monoclonal gammopathy of undetermined significance (MGUS) is an asymptomatic premalignant plasma cell disorder that is characterized by the presence of serum M-protein less than 30 g/lor 3 g/dl, bone marrow (BM) clonal plasma cells less than 10%, absence of plasma cell myeloma (PCM) related end-organ damage (CRAB symptoms: hypercalcemia, renal insufficiency, anemia and, bone lesions) and absence of B-cell lymphoma or other disease known to produce an M-protein. MGUS is generally considered a preneoplastic disorder that does not always progress to overt malignancy. Diverse endocrinopathies occur in patients with plasma cell disorders. One possible scenario is the rather rare POEMS syndrome, which is a paraneoplastic syndrome with key manifestations of polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, and skin changes. We present a case study which emphasizes the importance of multidisciplinary evaluation of MGUS.

The impact of endocrine diseases on mental health

Yu-Chun Lin[1] & Hassan Heshmati[2]
[1]Institute of Medicine, Chung Shan Medical University, Taichung City, Taiwan; [2]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, United States

Introduction
Endocrine diseases are linked not only to physical health issues but also to considerable psychological burdens that can negatively impact patients' overall well-being. This review seeks to examine different findings in this domain, investigating the connections between hormonal fluctuations and mental health outcomes, while also addressing novel approaches for diagnosis and treatment.
Methods
A systematic search of literature was conducted using the search terms endocrine diseases, mental health, well-being, and psychological interventions.
Results
The central nervous system has receptors for multiple hormones. Dysfunctions of the endocrine system can adversely impact the central nervous system either directly or through the consequences of the endocrine dysfunctions. The relationship between endocrine diseases and mental health has received heightened focus in recent years, as new studies revealed the significant impact that hormonal imbalances can have on psychological well-being. Endocrine diseases such as acromegaly, thyroid dysfunction (hyperthyroidism or hypothyroidism), parathyroid dysfunction (hyperparathyroidism or hypoparathyroidism), adrenal dysfunction (hypercortisolism or adrenal insufficiency), pheochromocytoma, diabetes, and hypogonadism, substantially affect the quality of life of a large number of patients. Most patients experience stress, low mood, and anxiety due to lack of serotonin. These emotions often drive individuals to opt for ultra-processed foods to quickly boost serotonin levels, leading to a vicious cycle and increasing the risk of conditions such as obesity and diabetes. These endocrine diseases disrupt the hormonal balance that regulates autonomic nervous system, cognitive function, stress response, and emotion, resulting in various mental health disorders like cognitive impairment, uncontrollable impulsive behavior, anxiety, depression, and psychosis. In addition to the appropriate treatment of the endocrine dysfunctions, psychological interventions such as cognitive-behavioral therapy and mindfulness-based stress reduction can enhance self-management skills, social functioning, and emotional well-being. The reported studies highlight the necessity of incorporating psychological care into the treatment of patients with endocrine diseases. Subsequent research should concentrate on empirical investigations to substantiate these insights and examine the practical application of the interventions in different clinical settings.
Conclusion
Endocrine diseases substantially affect the quality of life and lead to various mental health disorders such as cognitive impairment, anxiety, depression, and psychosis. The healthcare professionals should identify the underlying factors that may contribute to a patient's condition, fostering more accurate diagnoses and personalized treatment plans. By addressing the interplay between endocrine and mental health, providers can improve patient's outcome, enhance quality of life, and promote long-term well-being.

Endocrine and metabolic diseases associated with stress

Hassan Heshmati[1] & Yu-Chun Lin[2]
[1]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, United States; [2]Institute of Medicine, Chung Shan Medical University, Taichung City, Taiwan

Introduction
Stress is a non-specific response to a stressor. Stress is universal, affecting plants, animals, and humans. It can be acute or chronic. The stressor in humans covers a variety of situations such as physical activity, extreme temperature, noise, workload, unemployment, financial difficulties, food insecurity, divorce, racism, harassment, fear, violence, injury, disease, war, and death of a loved one. Stress can have multiple effects on physiology and behavior, impact child development, and cause several medical disorders. This review presents an update on endocrine and metabolic diseases associated with stress.
Methods
A systematic search of literature was conducted using the search terms stress, stressors, hormones, endocrines diseases, and metabolic diseases.
Results
During stress, the release of several hormones is affected (increased or decreased release). The hormones that are increased include corticotropin-releasing hormone, arginine vasopressin, adrenocorticotropic hormone, prolactin, cortisol, catecholamines, and neuropeptide Y. The hormones that are decreased include gonadotropin-releasing hormone, thyroid-stimulating hormone, luteinizing hormone, follicle-stimulating hormone, thyroxine, triiodothyronine, and insulin. Some of these hormonal changes may be necessary for a short-term protection but chronic stress can induce or potentiate several endocrine and metabolic diseases. Studies have reported that subjects with Cushing's disease (but not Cushing's syndrome), hyperprolactinemia (prolactin adenoma or idiopathic hyperprolactinemia), and Graves' disease (onset or relapse) have been exposed more to stressful life events than their matched controls. Stress in early life may be a risk factor for the development of type 1 diabetes. Gonadal function can also be impacted by stress resulting in oligospermia and impotence in men and menstrual irregularities, anovulation, and amenorrhea in women. Through multiple and complex biochemical changes, stress can induce abnormalities in food intake behavior and fat storage, causing weight gain (overweight, obesity) or weight loss (underweight). Decreasing the incidence of stressors and the reaction to them can prevent the occurrence of stress-related disorders. Several tools can be used. They include creation of a stress-free environment, relaxation techniques (soft music, yoga, and meditation), creative arts therapies (art, music, dance, and drama), herbal products (lemon balm and lavender), and medications (benzodiazepines).
Conclusion
Stress is a challenging experience with multiple effects on physiology and behavior and impact on child development. The abnormal release of several hormones during stress can cause endocrine and metabolic diseases. Stress is a significant global health issue imposing substantial societal costs. Establishing effective programs to reduce the incidence of stressors can help preventing the occurrence of stress-related endocrine and metabolic diseases.

Early detection of adrenal insufficiency after pituitary surgery: basal cortisol levels

Miguel-Angel Ruiz-Gines[1], Juan-Antonio Ruiz-Gines[2], Maria Zurdo-Lopez[1], Laura Cervera-Palou[1], Macarena Dubert-Perez[1] & Maria Ruiz-Ancos[3]
[1]Hospital Universitario de Toledo, Laboratory Medicine, Toledo, Spain; [2]Hospital Clínico Universitario Lozano-Blesa, Neurosurgery, Zaragoza, Spain; [3]Hospital Universitario de Toledo, Endocrinology, Toledo, Spain

Introduction
Transsphenoidal surgery (TS) is the surgical treatment of choice for pituitary lesions. Postoperative involvement of the hypothalamic-pituitary-adrenal axis is associated with high morbimortality, and it is essential to identify those patients who require corticosteroid replacement therapy. Our objective is to evaluate whether basal cortisol levels in the early postoperative period are related to the presence of adrenal insufficiency (AI) at 4 weeks after surgery.
Case Report
Retrospective and observational study, with a duration of 6 months. Patients with Cushing's disease, previous AI and treatment with preoperative corticosteroids were excluded. In total, 27 patients were studied. The postoperative hormonal assessment included ACTH and cortisol on the 3rd day and, subsequently, at 4 weeks after surgery. The necessary data were collected from the Medical History of each patient. The perisurgical management protocol with glucocorticoids after pituitary surgery published by the Spanish Society of Endocrinology (SEEN) in 2021 was used, considering AI cortisol values lower than 4.1mg/dl (sensitivity 95.1%, specificity 100%). The mean age was 35 ± 19 years, and they were more frequent in women (56%). The majority were non-functioning pituitary adenomas (52%), functioning ones (25%) and 21% were other types of tumors, with craniopharyngiomas and hamartomas standing out (the latter as triggers of central organic precocious puberty). Macroadenomas were considered to be tumors $\geq$ 1cm and microadenomas $<$ 1cm. The mean size of the lesions was 26 ± 17mm. The mean concentration of ACTH and cortisol on the 3rd day was 24 ± 14pg/ml (7.20-63.30) and 21 ± 8mg/dl (6.0-18.4) respectively; while at one month they were 22 ± 8pg/ml and 13 ± 9mg/dl. No patient with cortisol concentrations higher than 4.1mg/dl on day 3 postoperatively developed AI at week 4. Five patients (18.5%) developed AI (3 craniopharyngiomas, 1 hamartoma, and 1 nonfunctioning adenoma, with sizes greater than 25mm). In patients with AI, mean cortisol on day 3 was 3.1 ± 0.9mg/dl and at week 4 was 2.8 ± 0.6mg/dl.
Discussion and conclusions
A cortisol level higher than 4.1mg/dl on the 3rd postoperative day seems to prevent the development of AI and could allow to identify patients who need

glucocorticoid replacement therapy while awaiting confirmation of secondary AI by ACTH testing. In our study, ACTH was always within the reference values and did not allow us to discriminate those patients with secondary AI. It should be noted that most large sillar and/or suprasellar lesions (craniopharyngioma type) developed central AI. The SEEN protocol is safe and effective in patients undergoing TS.

Toxic pneumonitis in the context of cabergoline treatment

Raimonda Klimaite[1,2,3] & Aiste Stonyte[2]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Endocrinology, Kaunas, Lithuania

Introduction
In prolactinoma patients, first-line therapy typically involves cabergoline (CAB) or bromocriptine. Adverse effects occur in 2.5-29% of CAB-treated patients. While CAB is generally safe regarding pleuropulmonary side effects, this case highlights its rare association with toxic pneumonitis, emphasizing the need for awareness of such adverse reactions despite limited available data.
Case
A 77-year-old man was diagnosed in 2019 with clear cell renal cell carcinoma and lung metastases (pT3aN0MxLVIR0 G3). Surgical treatment and first-line therapy with Sunitinib were administered. In 2022, the patient was diagnosed with nodular goiter, Hashimoto's thyroiditis, and hypothyroidism, treated with Levothyroxine to achieve euthyroidism. Galactorrhea was present, accompanied by hyperprolactinemia and a pituitary microadenoma. Bromocriptine was initiated but discontinued due to intolerance. The medication was replaced with CAB at 125 µg/week, gradually increasing the dose to 500 µg/week. Galactorrhea resolved, but the patient developed dyspnea, cough, and chest pain without fever. **Blood tests** CRP 4.2 (<5) mg/l,K 4.5 (3.5-5.1) mmol/l,Na 139 (136-146) mmol/l,creatinine 110 (59-104) µmol/l,leukocytes 8.6x10^9/l(3.9-8.8), neutrophils 6.4x10^9/l(1.8-7.4). Inflammatory markers within normal range. **Blood gas analysis** pH 7.38 (7.35-7.45), pCO2 39 (35-45) mmHg, pO2 92 (80-100) mmHg, HCO3- 24 (22-26), BE -1.6 (-2-+2) mEq/l,SaO2 98 (95-100)%. **ECG** Demonstrates normal findings. **Echocardiography** Ejection fraction 55%, impaired diastolic function. **Chest CT** Broad irregular areas with consolidation and bronchograms were predominantly observed in the right lung, with similar findings bilaterally, suggesting organizing toxic pneumonitis without tumor progression. Radiological and biochemical findings indicated cabergoline-induced toxic pneumonitis, leading to medication discontinuation. **Follow-up** Symptoms of toxic pneumonitis resolved within two weeks, with follow-up chest CT at one month showing resolution of pulmonary changes. In dynamic monitoring, prolactin levels increased without galactorrhea, and dopamine agonists were not resumed. After 1 year, pituitary MRI showed no significant adenoma size change, prompting continued active monitoring.
Conclusions
This case highlights the rare association between CAB and toxic pneumonitis, emphasizing the need for clinicians to stay vigilant for pulmonary side effects in patients on cabergoline, especially with respiratory symptoms. Early detection and discontinuation of the medication are key to mitigating these adverse effects.

Analysis of miR 16-5p, miR 143-3p and miR 423-5p in patients with invasive non-functioning pituitary adenomas and prolactinomas

Aleksandra Derwich-Rudowicz[1,2], Aleksandra Żbikowska[3], Mirosław Andrusiewicz[3], Marek Ruchała[1] & Nadia Sawicka-Gutaj[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznan, Poland; [2]Poznan University of Medical Sciences, Doctoral School, Poznan, Poland; [3]Poznan University of Medical Sciences, Department of Cell Biology, Poznan, Poland

Background
MicroRNAs (miRNAs) are small non-coding RNA molecules involved in the post-transcriptional regulation of gene expression. Pituitary adenomas (PA) are the second most common intracranial neoplasm, with invasive adenomas, defined as the tumor invading surrounding structures and the focal or extensive bones, acounting for 22%– 55% of PA cases. As circulating miRNAs are stable in human body fluids, the study aimed to analyze miR 16-5p, miR 143-3p and miR 423-5p expression in serum of patients with invasive non-functioning pituitary adenomas (NFPA) and prolactinomas, as candidates for non-invasive biomarkers.
Material and Methods
That was a prospective study with consecutive enrollment. The study included 62 Patients with NFPA and 19 Patients with macroprolactinoma qualified for transsphenoidal surgical resection. Clinical history, laboratory and imaging results, and endocrine tests were recorded. Peripheral blood was collected. MicroRNAs, without the high molecular RNA fraction, were isolated from serum samples using the double-column system for miRNA and RNA isolation, according to the manufacturer's protocol (A&A Biotechnology, Gdansk, Poland). The qPCR was performed using SolisFAST Probe qPCR Mix with UNG (Solis Biodyne, Tartu, Estonia). The expression levels of hsa-miR-191-5p, hsa-miR-16-5p, hsa-miR-143-3p, and hsa-miR-423-3p were determined using TaqMan MicroRNA Assays (Thermo Fisher Scientific, Waltham, MA, USA). hsa-miR-191-5p served as a reference miRNA. Relative expression level analysis was performed using the same software by comparing the expression level of the genes of interest with that of the reference gene. The control group (CG) consisted of 26 healthy volunteers. The statistical analysis was performed with MedCalc, with significance level set as $P < 0.05$.
Results
The analysis involved 62 patients with NFPA (47% males) and 19 patients with macroprolactinoma (74% males). The total concentration of microRNA was significantly lower in NFPA than in the CG ($P = 0.0419$). We did not observe that for prolactinoma. No correlation between selected miRNAs and tumor type was found, miR-143-3p ($P = 0.4610$), miR-16-5p ($P = 0.8767$), miR-423-5p ($P = 0.1459$). The expression of miRNA also did not correlate with invasiveness (cavernous or sphenoid sinus invasion, compression of the optic chiasm). We observed significantly lower levels of FSH, LH, estardiol, testosterone and fT4 in NFPA and prolactinomas than in control group ($P < 0.05$). IGF-1 and fT3 were significantly lower in NFPA than CG ($P = 0.024$, $P = 0.0067$, respectively).
Conclusions
Although the total expression of microRNA was significantly lower in NFPA, miR 16-5p, miR 143-3p and miR 423-5p are not useful as non-invasive biomarkers in patients with invasive non-functioning pituitary adenomas and prolactinomas.

Early cardiovascular and metabolic benefits of rhGH therapy: positive changes in biomarkers and oxidative stress in adult-onset growth hormone deficiency

Maria Kościuszko[1], Angelika Buczyńska[2], Justyna Hryniewicka[1], Małgorzata Jacewicz-Święcka[1], Adam Krętowski[1] & Anna Popławska-Kita[1]
[1]Medical University of Białystok, Department of Endocrinology, Diabetology, and Internal Medicine, Białystok, Poland; [2]Medical University of Białystok, Clinical Research Center, Białystok, Białystok, Poland

Introduction
Adult-onset growth hormone deficiency (AO-GHD) increases mortality, mainly due to cardiovascular complications. Insulin-like growth factor 1 (IGF-1), a key mediator of growth hormone (GH) activity, is crucial for cellular growth, metabolism, and vascular homeostasis. IGF-1 deficiency in AO-GHD contributes to endothelial dysfunction, oxidative stress (OS), and elevated cardiovascular risk. Endothelin-1 (ET-1) regulates hypertension, atherosclerosis, and heart failure, while OS exacerbates vascular dysfunction via increased asymmetric dimethylarginine (ADMA), which reduces nitric oxide availability. This study evaluates recombinant human growth hormone (rhGH) therapy's impact on ET-1 and ADMA levels in AO-GHD, assessing its potential to reduce OS, improve endothelial function, and lower cardiovascular risk.
Methods
The study included 15 patients diagnosed with AO-GHD who underwent a 12-month course of rhGH therapy. IGF-1, ET-1, ADMA, total antioxidant capacity (TAC), and total oxidative capacity (TOC) were measured at baseline, 6 months, and 12 months. Body composition was assessed using dual-energy X-ray absorptiometry (DXA). Statistical analysis involved repeated-measures ANOVA and post hoc tests with Bonferroni correction.
Results
IGF-1 levels significantly increased at 6 and 12 months ($P = 0.0003$; $P = 0.0001$), while ET-1 decreased at 12 months ($P = 0.007$) and ADMA levels declined at both 6 and 12 months ($P = 0.01$). TOC decreased at 6 ($P = 0.02$) and 12 months ($P = 0.04$), whereas TAC increased at 12 months ($P = 0.02$). A

significant reduction in fat mass was observed at 6 months ($P = 0.006$), suggesting early improvements in body composition. IGF-1 correlated negatively with TOC ($P < 0.006$; $r = -0.73$) and positively with TAC ($P < 0.001$; $r = 0.83$). Post hoc tests confirmed significant differences between observation periods.

Conclusions

This study highlights the early therapeutic benefits of personalized rhGH treatment in AO-GHD, demonstrating significant cardiovascular and metabolic improvements within six months. The observed reductions in ET-1, ADMA, and TOC, alongside increases in TAC and IGF-1, suggest a potential reduction in cardiovascular risk and enhanced metabolic homeostasis. These findings support the monitoring of these biomarkers to optimize treatment strategies and improve patient outcomes.

Remission post endoscopic pituitary surgery for cushing's disease – experience of a regional tertiary centre in UK

Mohammed Salloum[1], Nijaguna Mathad[2], Alicja Knysak[1,2], Jana Bujanova[1] & Ma'en Al-Mrayat[1]

[1]Southampton General Hospital, Southampton, UK, 1-Department of Endocrinology, Southampton General Hospital, Southampton, UK, Southampton, United Kingdom; [2]2-Department of Neurosurgery, Wessex Neurology Centre, Southampton General Hospital, Southampton, UK, Southampton, United Kingdom

Background

This is service evaluation aimed to assess the remission rate against published literature of patients with confirmed diagnosis of Cushing's disease undergoing endoscopic endonasal pituitary surgery at a regional tertiary centre in the UK.

Methods

A cohort of 29 patients [19 females (65.5%) and 10 males (34.5%), aged 24–68 years] who underwent endoscopic surgical treatment for Cushing's disease at Southampton General Hospital (Southampton, UK) between 2016 and 2024 were included in this study. Demographics, clinical characteristics, preoperative diagnostic workup, and surgical outcomes were analysed. The confirmatory diagnostic tests employed included overnight (ODST) and low dexamethasone (LDDST) suppression tests (100%), pituitary MRI with contrast (100%), urinary free cortisol (100%), midnight salivary cortisol series (89%), inferior petrosal sinus sampling (31%, those with no visible adenoma on MRI or size <6mm), and methionine positron emission tomography (MET-PET) in cases of persistent or recurrent disease (20%).

Results

Preoperatively, 31% (9/29) of patients had type 2 diabetes mellitus, and 58% (17/29) were obese (BMI $\geq$ 30). MRI findings revealed macroadenomas in 31% (9/29) of patients and microadenomas in 69% (20/29). The overall remission rate was 82.8% (24/29), with early remission (postoperative morning cortisol < 55 nmol/lwithin one week) achieved in 51.7% (15/29) of patients. Delayed remission occurred in 31% (9/29); defined as subsequent normalising of urinary free cortisol and salivary cortisol level, or ongoing need for patients' glucocorticoids replacement. Persistent disease was observed in 17.2% (5/29) of patients. Remission rate was highest for microadenomas (90%, 18/20) compared to macroadenomas (55.5%, 5/9). Of those with macroadenomas, 33.3% (3/9) achieved early remission, 22.2% (2/9) had delayed remission, and 44.4% (4/9) with persistent disease. Cavernous sinus involvement was present in 31% (9/29) of patients and was associated with a lower remission rate [55.5% (5/9)]. Histology confirmed the diagnosis of corticotroph adenoma in 86.2% (25/29) of patients, with one case of ACTH staining gangliocytoma (3.4%, 1/29) and four cases of Crooke's hyaline changes (13.8%, 4/29). Of the Crooke's hyaline change cases, two had macroadenomas, one had delayed remission, and one had persistent disease, while all patients with microadenomas and Crooke's changes achieved early remission.

Conclusion

Endoscopic surgery for Cushing's disease at our centre yielded a favourable remission rate of 82.8%, with early remission occurring in over half of the patients. Adenoma size and cavernous sinus involvement were significant predictors of remission, with smaller microadenomas and the absence of cavernous sinus involvement associated with better outcomes.

Recovery of gonadal axis in patients with prolactinomas

Joob Ruben Müller[1], Sara Nader-Müller[2], Catharina Bullmann[2], Leena Shahla[3] & Birgit Harbeck[2,4]

[1]Department of Radiology and Neuroradiology, Asklepios Klinik Altona, Hamburg, Germany; [2]amedes Facharztzentrum für Kinderwunsch, Pränatale Medizin, Endokrinologie und Osteologie, Internistische Endokrinologie, Hamburg, Germany; [3]Duke University, Department of Endocrinology, Durham, United States; [4]University Hospital Hamburg-Eppendorf, Department of Rheumatology, Nephrology and Endocrinology, Hamburg, Germany

Introduction

Prolactinomas are the most common pituitary adenomas, leading to an increased secretion of prolactin. The symptoms vary and include symptomatic as well as asymptomatic courses. Symptoms are mainly caused by suppression of the hypothalamic–pituitary–gonadal axis (HPG axis). This causes galactorrhea, infertility, oligo-amenorrhea, impotence and osteoporosis as well as symptoms of mass effect (hypopituitarism, visual loss, optic chiasm compression, headaches). For most patients dopamine agonist therapy with Cabergoline represents the primary and most effective therapy. For individual therapy planning the knowledge of influencing factors and disease progression is essential. Our goal was to examine the time period until HPG axis is normalized, as well as the role of influencing factors.

Patients and methods

We retrospectively analyzed the data of patients who were treated in the specialist center of Amedes experts Hamburg between 2013 to 2023 from diagnosis until remission. From initially 410 patients 66 patients fulfilled all inclusion criteria. Diagnosis of suppressed HPG-axis was made by measuring diminished serum concentrations of LH, FSH, estradiol and testosterone. We measured the time period until those concentrations normalized under Cabergoline-therapy and assessed for a significant correlation between this time period and influencing factors using Spearmans rank correlation coefficient and non- parametric Mann-Whitney-U-Test.

Results

The mean duration until normalization of HPG axis under Cabergoline-therapy was 82 days. Statistical analysis showed significant correlation between this duration and initial prolactin levels as well as gender and age. Thus, patients with higher initial prolactin levels, older patients and males showed longer treatment durations. There was no correlation between the time period and adenoma size, Cabergoline dosage, comedication and accompanying diseases.

Conclusions

The acquired data allows for a more precise estimation of treatment duration and patient counseling. Furthermore, it can be useful in creating long term therapy concepts. Patients with prolonged suppression of HPG-axis could receive early hormonal replacement therapy if needed.

Adiposity trajectories and predictors of obesity in patients with childhood-onset craniopharyngioma

Byungsun Yoo[1], Joo Whan Kim[2], Yun Jeong Lee[1], Jeesun Yoo[1], Yongbeom Cho[1], Uisook Song[1], Yong Hwy Kim[2], Ji Hoon Phi[2], Seung-Ki Kim[2], Choong Ho Shin[1] & Young Ah Lee[1]

[1]Seoul National University Children's Hospital, Seoul National University College of Medicine, Department of Pediatrics, Seoul, South Korea; [2]Seoul National University Children's Hospital, Seoul National University College of Medicine, Department of Neurosurgery, Seoul, South Korea

Objective

Hypothalamic obesity may affect long-term quality of life in patients with craniopharyngioma (CRP). We investigated factors influencing body mass index (BMI) z-scores and overweight or obesity(OWOB) over a 5-year postoperative follow-up in childhood-onset CRP patients.

Methods

We retrospectively reviewed 110 CRP patients (65 males), who underwent surgery (median age 8.0 years) between June 1998 and June 2019 with at least 5 years of follow-up without recurrence. Age at surgery, 2 kinds of hypothalamic involvement (HI) [Puget grade 0-1 vs. 2 ($n = 68$) and SNUH grade (29 anterior, 39 middle, 41 posterior)], surgical approach, timing of growth hormone (GH) initiation (within 3 year and 3+ years), and intensive lifestyle education (before or after year 2014) were included as factors affecting BMI z-scores over a 5-year period or OWOB at 5 years postoperatively.

Results
Significant changes were found in BMI z-scores and the rates of OWOB from the time of surgery (34.2%), to 1, 2, 3, and 5 postoperative years (48.2%, 43.7%, 39.1%, and 36.3%, respectively). In OWOB group at the time of surgery, BMI z-scores decreased significantly over a 5-year period ($P < 0.001$). In a linear mixed model, significant difference was found in BMI trajectory over a 5-year period between age groups at surgery (below or above 8.0 years of age) and between HI groups ($P < 0.001$ for all). BMI z-scores over a 5-year period are greater in higher HI compared to lower HI group [Puget grade (2 vs. 0-1, $P < 0.01$) and SNUH grade (posterior vs. anterior and middle, $P < 0.01$)]. No significant differences were observed based on surgical approach, timing of GH initiation, or lifestyle education interventions. When multivariate-adjusted model was constructed including age at diagnosis, initial BMI category and each HI grade, not only age at surgery and initial OWOB (both $P < 0.01$) but also Puget grade ($P = 0.001$) and SNUH grade ($P = 0.007$) were significant factors for OWOB at 5 years postoperatively.
Conclusions
While HI was common in childhood-onset CRP patients, with one third of patients classified as OWOB at diagnosis, the rates of OWOB increased until the first postoperative year and then showed a decreasing trend over a 5-year period. Age at diagnosis, initial BMI category, and high HI grade were independent predictors for postoperative 5 year OWOB. Children who are older ($\geq$ 8.0 years of age), severely damaged hypothalamus, and obese at diagnosis are at high risk of being obese 5 years after surgery.

JOINT2316

Cannulated prolactin test: a diagnostic approach to moderate hyperprolactinemia

Natalia Karlovich[1], Maryia Malyshko[2], Tatsiana Mokhort[1] & Alena Yurenia[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk Clinical Endocrinological Center, Minsk, Belarus

The aim was to determine the effectiveness of cannulated prolactin test in patients of reproductive age with moderate hyperprolactinemia (HP) and to analyze the frequency of specific and nonspecific complaints.
Materials and Methods
We examined 272 patients, 195w, 77m; age 30.2±9.9 yrs. After cannula insertion, prolactin was measured at 0(PRL0), 60(PRL1), and 120 minutes (PRL2). The results of the cannulated prolactin test (CPT) were considered positive- with HP remaining in all three samples (PRL0, PRL1, PRL2), negative -if HP was at PRL0 and/or PRL1 and without HP in all samples of the test. HP was diagnosed in accordance with the recommendations of the Endocrine Society: >20 ng/ml in men and >25 ng/ml in women. Mild HP is defined in men as a serum prolactin concentration between 19.5 and 100 ng/ml and in women 26.6 and 100 ng/ml.
Results
Median PRL0 was 30.1(21.2-41.2) ng/ml, median PRL1 24.8 (17.5-34.7) ng/ml and median PRL 2 ng/ml 19.5 (13.66-28.9). Approximately 1/3 (30.5%) of the patients reached a normal PRL0. Positive CPT was detected as pathological HP in 37.5% patients. Negative CPT was detected as stress-induced HP in 62.5 % patients. Determination of PRL0 with reference to pathological HP result in a high specificity and moderate sensitivity (sensitivity 54.1%, specificity 100.0%, positive predictive value (PPV) 100.0%, and negative predictive value (NPV) 51.8%, accuracy 69.3%). Determination of PRL1 with reference to pathological HP result in a high specificity and moderate sensitivity (sensitivity 67.1%, specificity 100.0%, positive predictive value (PPV) 100.0%, and negative predictive value (NPV) 71.76%, accuracy 82.1%). 216 patients (73.8 % of women and 79.2 % of men) had complaints, of them patients 161 (57.6 % women and 61 % men) had specific to HP (galactorrhea, menstrual disorders, reduced libido, infertility, gynecomastia, breast pain), 80 patients (25.3 % of women and 30 of men) had non-specific complaints (weight gain, acne, headache, dizziness, scrotum pain, fatigue). The main presenting symptom was gynecomastia in 40.3% of man, and menstrual irregularities in 36.2% of the women.
Conclusion
The cannulated prolactin test was useful in excluding pathological HP, stress-induced HP (negative CPT) was determine in 62.5% of patients. Patients with stress-induced HP (negative CPT) and patients with pathological HP (positive CPT) had no statistically significant differences in age and frequency of occurrence of specific and non-specific complaints and symptoms for HP. Determination of PRL in CPT with reference to pathological HP result in a moderate sensitivity and high specificity.

JOINT3034

Celebral salt wasting syndrome in a patient with known central diabetes insipidus on the background of mcap overgrowth syndrome

Panagiota Georgia Maltezou[1], Vasiliki Bekiou[1], Argyrios Ntinopoulos[2], Melpomeni Giorgi[2], Maria Spanou[2], Vasiliki Zouvelou[2], Maria Angeli[2], Artemis Stephanede[2], Eftstathios Stefos[2], Kiriaki Chatziagapiou[1] & Foteini-Eleni Karachaliou[1]
[1]Pediatric Endocrinology Unit, Athens University Hospital Attikon, Athens, Greece, Athens, Greece; [2]Pediatric Neurology Unit, Athens University Hospital Attikon, Athens, Greece, Athens, Greece

Introduction
Salt-wasting syndrome constitutes a significant disorder of sodium and water homeostasis, commonly observed in individuals with intracranial pathology, such as central nervous system infections, cerebral ischemia, elevated intracranial pressure, or following neurosurgical procedures. Central diabetes insipidus is another disorder affecting sodium homeostasis and is associated with these conditions. The coexistence of these two disorders poses a substantial challenge for pediatric endocrinologists, particularly in critically ill patients.
Aim/Methods
We present the case of a patient with MCAP overgrowth syndrome who developed salt-wasting syndrome on the background of pre-existing central diabetes insipidus.
Results
The patient had a known history of MCAP syndrome (megalencephaly, macrocephaly, polymicrogyria), with genetic testing revealing a mutation in the PIK3CA gene. At 13 months of age, the patient underwent ventriculoperitoneal shunt placement. Postoperatively, he developed central adrenal insufficiency, central hypothyroidism, and central diabetes insipidus, and treatment with hydrocortisone, levothyroxine, and desmopressin was initiated. Six months later, due to Chiari type 1 malformation, a decompressive laminectomy at the A1 level was performed. At 20 months of age, the child presented with fever of central origin, and brain CT revealed the presence of subdural hygromas. The patient was treated with prednisolone. Laboratory findings demonstrated hyponatremia, mildly elevated urea, low urine specific gravity (SG = 1001), and natriuresis (urinary sodium = 49 mmol/L). The diagnosis pointed towards salt-wasting syndrome, and treatment included oral sodium supplementation and fludrocortisone.
Conclusions
Salt-wasting syndrome is an important cause of hyponatremia and clinical dehydration, particularly in the setting of structural and functional abnormalities of the central nervous system. It must be differentiated from syndrome of inappropriate antidiuretic hormone secretion (SIADH). The pathophysiology of salt-wasting syndrome involves both sympathetic nervous system dysfunction and the secretion of natriuretic peptides in response to brain pathology. The coexistence of salt-wasting syndrome with central diabetes insipidus is rarely reported in pediatric populations. Nevertheless, progressive central nervous system damage or repeated neurosurgical procedures are risk factors that warrant heightened vigilance by treating physicians.

Challenging management of electrolyte imbalances in neurosurgical patient: cerebral salt wasting case report

Alessio Rossi[1,2], Laura Corbelli[1,2], Sara Soldovieri[1,2], Alessandro Barbato[1,2], Matteo Cerutti[1,2], Matteo Pontone[1,2], Eugenio Trinati[1,2], Giovanna Municchi[2] & Stefano Stagi[1,2]
[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Diabetology and Endocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy

Introduction
Electrolyte disorders are common in central nervous system (CNS) diseases, including subarachnoid hemorrhage, traumatic brain injury, cerebral tumors, infections and postoperative neurosurgical setting. These conditions can be associated with both the syndrome of inappropriate secretion of antidiuretic hormone (SIADH) and to cerebral salt wasting (CSW). Hypothalamic-neurohypophyseal system affections instead, can lead to central diabetes insipidus (CDI). CSW is characterized by hyponatremia and hypovolemia due to excessive sodium loss in urine. SIADH presents as euvolemic hyponatremia due to inappropriate ADH secretion. CDI is primarily characterized by polyuria due to insufficient ADH. The table below summarizes the key differences among these

	Urine volume	Urine Na concentration	Plasma Na concentration	Extracellular fluid volume	Fluid balance
SIADH	↔ or ↓	↑	↓	↑	↔ or ↑
CSW	↔ or ↑	↑	↓	↓	↓
CDI	↑	↓	↔ or ↑	↓	↔ or ↓

syndromes to avoid misdiagnosis and inappropriate therapy. We present a case of a child with chiasmatic-hypothalamic tumor who developed post-surgery fluid and electrolyte imbalance, detailing the initial neurosurgical and intensive care approach and subsequent endocrine management.
Case presentation
A 3-years-old girl with chiasmatic-hypothalamic astrocytoma underwent lesion debulking surgery. Intraoperatively and postoperatively, she presented polyuria (5 mL/kg/h) with normal natremia. Desmopressin and sodium chloride infusion were administered. The next day she developed hyponatremia (Na 130 mEq/l) with persistent polyuria, prompting a second desmopressin bolus. On post-operative day two, diuresis increased (10 mL/kg/h) and laboratory tests showed: Na 125 mEq/l,K 3.2 mEq/l,urinary Na 164 mEq/L. Suspecting CSW, endocrinologist specialist recommended stopping desmopressin, initiating hypertonic saline and administering fludrocortisone (0.05 mg twice daily). Strict fluid balance monitoring and electrolyte surveillance were emphasized. Hypokalemia, likely due to mineralocorticoid therapy, was corrected with potassium infusion. As fluid and electrolytes stabilized, sodium and potassium supplementation were gradually discontinued, and fludrocortisone was reduced.
Discussion
Accurate determination of the patient's volume status is the key to diagnose CSW and to differentiate from SIADH, while natremia and urine concentration can help to rule out CDI. Hyponatremia in CSW must be corrected gradually to prevent osmotic demyelination. Fludrocortisone therapy may induce hypokalemia, requiring frequent monitoring of sodium and potassium levels. Proper diagnosis and management are key to avoid complications.

Pituitary apoplexy: epidemiology, presentation and outcomes - a population-based study in malta

Lianne Camilleri[1,2], Josanne Vassallo[1,2] & Mark Gruppetta[1,2]
[1]Department of Medicine, Faculty of Medicine and Surgery, University of Malta, Mater Dei Hospital, Msida, Malta; [2]Neuroendocrine Clinic, Department of Medicine, Mater Dei Hospital, Msida, Malta

Aims and Objectives
To determine the prevalence, incidence and outcomes of pituitary apoplexy patients presenting acutely in Malta.
Methodology
Twenty-nine patients presenting with pituitary apoplexy between 1980 and 2023 were retrospectively identified. The prevalence and incidence rates were calculated. Clinical presentation, endocrinological, radiological findings and outcomes of all patients with pituitary apoplexy were analysed and compared between the two cohorts who were treated conservatively or with early surgical intervention, taking into consideration serum prolactin levels at diagnosis. The Pituitary Apoplexy Score (PAS) was applied retrospectively.
Results
Five from 29 patients had a known pituitary adenoma. The prevalence for pituitary apoplexy was 4.61/100,000 individuals (NFPA 3.69/100,000; functional adenoma 0.92/100,000) and the overall SIR was 0.19/100,000/year (NFPA 0.144/100,000/year; functional adenoma 0.047/100,000/year). Prevalence rates and SIR were higher amongst males (prevalence 8.08/100,000 in males vs 0.78/100,000 in females). 92% of the patients who presented with apoplexy were macroadenomas, whilst 8% were microadenomas. The median age for apoplexy was found to be 51 years (IQR 42-58); higher in the NFPA subtype; 55 (IQR 49.5-63) when compared to 43 (IQR 38.5-45.25) in the functional group. Visual field defects were more prevalent when baseline prolactin levels were less than 5ng/ml; 68.75% vs 42.86% ($P = 0.014$). Complete pituitary function was preserved in 7.18%, whilst 78.57% showed panhypopituitarism and 14.29% exhibited partial hypopituitarism. Whilst 72.41% were initially managed conservatively, 27.59% were surgically treated and underwent trans sphenoidal decompression of the sella, within 7 days of presentation. There was no difference in terms of endocrinological outcome at 3 or 12 months between the surgically and conservatively treated group. At 12 months, 7.14% retained pituitary function, whereas 75% experienced panhypopituitarism and 17.86% exhibited partial hypopituitarism. Three from 27 patients (11.11%) were reported to have regrowth post apoplexy and 1 patient had recurrence of apoplexy in the tumour remnant. Utilising a lower PAS threshold, a comparative analysis showed that 87.5% of patients who underwent early surgery had a PAS ≥ 4, whilst 26.32% of those treated conservatively had a PAS ≥ 4 ($P < 0.001$).
Conclusions
Through thorough case identification, this study provides both prevalence and incidence rates of pituitary apoplexy in a well-defined population in Malta. Clinical sequelae and various treatment modalities have been studied to better understand this rare condition.

Clinical and hormonal features of prolactinomas in men

Mouna Elleuch[1], Yassmine Abdelkafi[1], Zaineb Fourati[1], Hamdi Frikha[1], Malek Hadrich[1], Faten Haj Kacem Akid[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Pituitary adenomas account for approximately 15% of all brain tumors. The most common hormone-secreting pituitary tumors are prolactinomas, which represent nearly 40% of all pituitary adenomas. Prolactinomas are three times more frequent in women but exhibit different features in men.
Methods
We reviewed clinical and hormonal data of 36 men followed for prolactinoma from 2000 to 2023 in a referral endocrine center of the region of Sfax, Tunisia.
Results
The mean age at diagnosis was 43.6 $\pm$ 15.1 years, with extremes ranging from 19 to 75 years, and a peak incidence at 41.5 years. The mean diagnostic delay varied between 2 weeks and 14 years, with an average latency of 15.3 $\pm$ 17.2 months. Pituitary tumor syndrome was the initial presentation for the majority of patients (94.4%). Headaches were the most common presenting symptom (86.1%). Visual disturbances were reported in 25 patients (69.4%). Pituitary apoplexy revealed the prolactin-secreting adenoma in 6 patients (16.7%), while incidental discovery was noted in 2 patients (5.6%). The endocrine hyperprolactinemia syndrome was dominated by sexual dysfunction, including erectile dysfunction and decreased libido in 17 patients (47.2%). Visual field examination was performed in patients with visual disturbances and was abnormal in 61.1% of cases (22 patients). Bitemporal hemianopia was identified in 22.2% of cases. The mean prolactin level was 18,662.18 $\pm$ 52,817.93 ng/ml, with extremes ranging from 46.7 ng/ml to 274,400 ng/ml. A positive and statistically significant correlation was observed between prolactin levels and prolactinoma size (rho $= 0.658$, $P = 0$). Regarding other hormonal assays, gonadotropic insufficiency was observed in 23 patients (63.88%), thyrotropic insufficiency in 16 patients (47.05%), corticotropic insufficiency in 22 patients (61.11%), and somatotropic insufficiency in 4 patients (11.11%). Additionally, 44.4% of patients had deficits in three axes, involving gonadotropic, corticotropic, and thyrotropic insufficiencies.
Conclusion
Although prolactinomas are rare in men, their clinical presentation can be more severe. It is therefore essential to consider this diagnosis in order to prevent significant impacts on quality of life, fertility, and visual disturbances.

Arginine vasopressin resistance - rare clinical cases

Mariia Berlovich[1], Laura Ebanoidze[1], Ekaterina Pigarova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Arginine vasopressin resistance (AVR) is a rare disorder with both congenital and acquired causes. Primary AVR is linked to mutations in the *AVPR2* and *AQP2* genes, while secondary AVR can result from conditions such as ureteral obstruction, a rare yet potentially reversible cause that remains under-researched. We present two clinical cases of primary and secondary AVR. Despite differing etiologies, both patients exhibited similar symptoms from an early age.
Clinical Case 1
Patient P., a 24-year-old male, has had AVR since birth. Bilateral hydronephrosis was diagnosed in utero at 32 weeks of gestation. By age 7, urine output had reached 5 liters per day. His clinical diagnosis included bilateral megaureter, meatal stenosis, a

posterior urethral valve, and secondary pyelonephritis. He underwent a meatotomy and endoscopic resection of the posterior urethral valve. At age 7, AVR was confirmed via a water deprivation test and desmopressin challenge. Despite treatment with hydrochlorothiazide and desmopressin, he continued to experience persistent polyuria, nocturia, fatigue, and difficulty concentrating. At 22 years, he was diagnosed with chronic kidney disease (CKD) stage 4. Due to progressive renal decline, renal replacement therapy and placement on the kidney transplant waiting list were recommended.
Clinical Case 2
Patient G., a 37-year-old male, was first hospitalized in the neuroendocrinology department at age 23 with severe thirst, nocturia, and polyuria of up to 16 liters per day. His symptoms had begun in childhood, with urine output reaching 20 liters daily by age 7. Despite prior desmopressin therapy, his condition remained unresponsive. AVR was confirmed through a water deprivation test and desmopressin challenge. Genetic testing identified a hemizygous *AVPR2* mutation (c.539delA p.R180fsX211), confirming the diagnosis. Treatment with thiazide diuretics and potassium supplements led to a significant reduction in thirst and urine output, stabilizing at 4–5 liters per day.
Conclusions
AVR in childhood is rare, with often nonspecific clinical manifestations. Regardless of etiology, timely and accurate diagnosis is crucial, as affected patients are at risk for hypernatremic dehydration and developmental delays. Increasing awareness among healthcare providers, particularly pediatricians, is essential to ensure proper evaluation of polyuria-polydipsia syndrome and a systematic approach to diagnosing arginine vasopressin disorders.

JOINT1582

Clinical case of arginine vasopressin resistance associated with a new mutation in the AVPR2 gene

Yulia Aleynikova[1], Mariia Berlovich[1], Ekaterina Pigarova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Arginine vasopressin resistance (AVR) is an orphan disease clinically characterized by severe polydipsia and the excretion of large volumes of dilute urine. Hereditary AVR is linked to mutations in the vasopressin receptor gene predominantly in 90% of cases, which is expressed in the renal collecting ducts (*AVPR2*). We present a clinical case of AVR in a patient with a mutation in *AVPR2* (hemizygous mutation c.587T>C p.Phe196Ser), which has not been previously described in the literature.
Clinical Case
Patient K., a 29-year-old male, presented to the Endocrinology Research Centre (ERC) with complaints of thirst, polyuria up to 15 liters per day, and nocturia. The diagnosis of arginine vasopressin disorder (AVD) was confirmed at age 3 against a water deprivation test. Desmopressin therapy was initiated without clinical effect. Magnetic resonance imaging (MRI) did not reveal any structural abnormalities of subcortical brain structures. At the ERC a desmopressin test was conducted, which showed no increase in urine osmolality. Genetic sequencing of the *AVPR2* revealed a hemizygous transition, resulting in a substitution of cytosine for thymine in exon 2 at position 587 (c.587T>C), leading to the amino acid substitution of phenylalanine (Phe) for serine (Ser) at position 196 of the receptor protein (p.Phe196Ser). This mutation has not been documented in medical literature. The patient was prescribed hydrochlorothiazide at a dose of 25 mg twice daily along with potassium supplements, while being monitored for diuresis and electrolyte levels. After two weeks, the patient reported a reduction in thirst, and urine volume significantly decreased. However, due to discomfort and "tingling" sensations behind the sternum, accompanied by hypokalemia, the patient independently discontinued medication, after which potassium levels normalized and the uncomfortable sensations subsided. AVR symptoms recurred. Given the development of hypokalemia despite potassium supplementation while on hydrochlorothiazide, therapy with non-steroidal anti-inflammatory drugs (NSAIDs) was initiated without significant clinical improvement. It was decided to resume hydrochlorothiazide treatment at a reduced daily dose (25 mg) alongside potassium supplements, while a potassium-sparing diuretic (amiloride) was also introduced at a dose of 5 mg daily. Patient monitoring continues.
Conclusions
AVR is a rare disease with social significance. Timely and accurate diagnosis not only prevents severe complications and initiates adequate treatment but also significantly enhances the patient's quality of life. The vigilance of primary care physicians in the presence of polydipsia-polyuria syndrome, competent patient routing, and an interdisciplinary approach are crucial in diagnosing and managing patients with AVR.

JOINT1344

Longitudinally assessed sex-typed play behaviour and its association with androgen levels during minipuberty in full-term and preterm children

Johanna Eronen[1], Ulla Sankilampi[1] & Tanja Kuiri-Hänninen[1]
[1]University of Eastern Finland, Kuopio, Finland

Context
Higher androgen levels during minipuberty have been associated with more masculine sex-typed play behaviour in full-term (FT) infants. On the other hand, reduced sex-typed play behaviour has been reported in preterm (PT) children at the age of five years.
Aim
To investigate the longitudinal development of sex-typed play behaviour and its association with testosterone and DHEAS levels during minipuberty in FT and PT children.
Methods
A standardized psychometric questionnaire Preschool Activities Inventory (PSAI) was used to measure the sex-typed play behaviour in 54 FT (boys $n = 26$) and 91 PT (boys $n = 44$) children at three time points: infancy (mean age (SD) 1.2 (0.1), $n = 117$), early childhood (EC, 3.1 (0.3), $n = 89$) and late childhood (LC, 9.1 (0.7) $n = 63$). Higher PSAI score indicates more masculine and lower score more feminine behaviour. Urinary testosterone and DHEAS levels during minipuberty were measured using HPLC-MS/MS. Spearman's correlation and mixed model were used for statistical analyses.
Results
Both testosterone and DHEAS levels in minipuberty were significantly ($P < 0.001$) higher in PT than in FT infants. DHEAS levels did not differ between sexes, but testosterone levels were higher in boys than in girls ($P < 0.001$). Notably, testosterone levels in PT girls were at the same level as in FT boys. In all the children, testosterone level correlated positively with PSAI in infancy (Spearman's rho 0.230, $P = 0.013$) and in EC (rho 0.339, $P = 0.001$), but not in LC (rho 0.194, $P = 0.132$). However, no significant associations were observed in the subgroups. In PT boys, DHEAS correlated negatively with PSAI in infancy ($P = 0.036$), but in the other multivariate analyses including the number of brothers and sisters and the age, neither testosterone nor DHEAS levels were associated with PSAI scores.
Conclusions
Prematurity seems to affect the longitudinal development of the PSAI score, but the differences are small. Urinary T or DHEAS measured during minipuberty were not associated with PSAI score after early childhood.

Table 1.

	Infancy		Early childhood (EC)		Late childhood (LC)	
Boys	FT	PT	FT	PT	FT	PT
PSAI	62.2 (4.4)	59.8 (7.8)	63.5 (8.7)	61.9 (7.4)	66.3 (7.0)	68.1(7.4)
Change from infancy to EC			not significant (NS)	NS		
Change from EC to LC					NS	$P < 0.001$
Girls	FT	PT	FT	PT	FT	PT
PSAI	44.1 (7.5)	44.7 (9.2)	33.6 (8.9)	32.0 (9.2)	34.1 (9.3)	39.2 (8.7)
Change from infancy to EC			$P < 0.001$	$P < 0.001$		
Change from EC to LC					NS	$P = 0.002$

MRI findings in girls with central precocious puberty: a comparative study with control group and their association with pubertal diagnosis and progression

Victor Cugi Gonçalves[1], Angelo Chelotti Duarte[2], Ana Luiza Padua Aratangy Pontes[3], Carlos Alberto Longui[1,3], Antônio José da Rocha[2] & Cristiane Kochi[1,3]
[1]Irmandade da Santa Casa de Misericórdia de São Paulo, Unidade de Endocrinologia Pediátrica, São Paulo, Brazil; [2]Irmandade da Santa Casa de Misericórdia de São Paulo, Departamento de Radiologia, São Paulo, Brazil;

[3]Santa Casa de São Paulo, Faculdade de Ciências Médicas, São Paulo, Brazil

Context
Central precocious puberty (CPP) has a complex etiology that involves a variety of conditions. Although approximately 90% of cases in girls are classified as idiopathic, a subset presents additional imaging findings that may have clinical significance.
Objective
To compare the frequency of brain magnetic resonance imaging (MRI) findings between girls with CPP and a control group and analyze, in CPP patients, their relationship with pubertal diagnosis and progression.
Methods
Data were collected between April 2017 and November 2024 from 102 girls who exhibited clinical pubertal progression before the age of 8 and underwent brain MRI, as well as 25 girls and 72 boys with other conditions, the majority diagnosed with idiopathic short stature, who also underwent brain MRI. The data evaluated were chronological age (CA), height SDS (zH), body mass index SDS (zBMI), bone age (BA), LH levels at diagnosis and after follow-up.
Results
Abnormal MRI findings were observed in 38 girls (37.3%) from the CPP group and in 19 individuals (19.6%) from the control group (z test, $P < 0.05$). Among the 38 abnormalities in the CPP group, 33 (32.4%) where classified as indeterminate (I) (e.g., inter-hypothalamic adhesion, pars intermedia cyst, pineal gland cyst), while 5 (4.9%) were classified as pathologic lesions (PL) (e.g., hypothalamic-optochiasmatic glioma, hydrocephalus). In the control group, all 19 abnormalities were limited to I, with no cases of PL. Girls with CPP due to PL exhibited a shorter interval between the diagnosis and the start of pubertal suppression therapy ($P = 0.017$) and showed less advanced bone age relative to chronological age at diagnosis ($P = 0.035$). No significant differences were found among the CPP subgroups in terms of age at puberty onset, age at diagnosis, BA at diagnosis, bone age-corrected height SDS, baseline LH, LH peak after GnRH stimulation, CA at initiation and discontinuation of pubertal suppression therapy, or age at menarche.
Conclusions
It is essential to perform MRI on all girls with CPP, including those aged 6-8 years, since they may also have undiagnosed PL. There were no differences in CPP group patients with or without abnormal MRI findings in relation to clinical or laboratory data. While indeterminate findings are more frequent in girls with CPP compared to the control group, these cannot yet be established as a cause or indicative of a different progression of puberty.
Key words
precocious puberty; MRI; glioma; inter-hypothalamic adhesion.

Novel score of autonomic dysregulation in children with hypothalamic syndrome

Nathalie Doelman-Oldenburger[1,2], Hermann Müller[3] & Hanneke van Santen[1,2]
[1]University Medical Center Utrecht, Wilhelmina Children's Hospital, Department of Pediatric Endocrinology, Utrecht, Netherlands; [2]Princess Máxima Center, Utrecht, Netherlands; [3]Klinikum Oldenburg AöR, University Children's Hospital, Carl von Ossietzky Universität Oldenburg, Department of Pediatrics and Pediatric Hematology/Oncology, Oldenburg, Germany

Objective
Rapid-onset Obesity with Hypothalamic dysfunction, Hypoventilation and Autonomic Dysregulation (ROHHAD) is a rare syndrome manifesting in childhood. Diagnosis of ROHHAD syndrome remains challenging due to the diversity of symptoms that may be missed easily, especially for autonomic dysfunction. The diagnostic criteria for the hypothalamic syndrome (HS) (van Santen *et al*, 2023) are a novel tool for recognizing symptoms of hypothalamic dysfunction. However, symptoms of autonomic dysregulation are lacking in these criteria. They are therefore insufficient for use in ROHHAD patients. No other scoring system for autonomic dysfunction in ROHHAD syndrome exists. We aim to improve the diagnostic criteria for HS by including a score for autonomic dysregulation, supporting early diagnosis of ROHHAD syndrome.
Methods
A score for autonomic dysregulation in ROHHAD syndrome supplementary to the diagnostic criteria for HS was developed based on existing instruments to assess autonomic dysfunction symptoms adjusted for specific symptoms in ROHHAD syndrome, with a score ranging from 0-10. The diagnostic criteria for HS including our add-on were tested retrospectively in 4 ROHHAD patients.

Table 1. Suggested add-on score autonomic dysregulation.

Clinical symptoms	Score
Ophthalmological dysfunctionStrabismusOculomotor apraxiaAltered pupil reactions to lightPtosisAltered vision	0-1-2
Altered peripheral vaso- or secretomotor tonelce-cold extremitiesFacial flushing/rednessAberrant sweating Dry mouthDry eyes	0-1-2
Pain threshold Decreased Increased	0-1-2
Gastrointestinal or bladder dysmotilityConstipationDiarrhea Bladder dysfunction	0-1
Cardiovascular manifestationsBlood pressure regulationOrthostatic intolerance Decreased heart rate variabilityArrhythmiaExercise intolerance	0-1-2
Torticollis	0-1
Total (out of 10)	

0 = no or normal, 1= yes/minor, 2=major. Total score: 0-3 = no autonomic dysregulation 3-6 = mild autonomic dysregulation 7-10 = severe autonomic dysregulation .

Table 2. Suggested updated hypothalamic score.

Clinical criteria
Hyperphagia
Hypophagia
BMI
Behavior
Sleep
Core temperature regulation
Pituitary function
Autonomic dysregulation
Pre-test probability
Presence of HS (yes/no)

Presence of HS is assessed by combining the clinical criteria using cut-off as presented by van Santen et al (2023).

Results
Four ROHHAD patients, median age 9.4 years (range 4.6-25.7), were assessed regarding signs and symptoms of HS and autonomic dysfunction. All patients had HS and scored on at least 3 different domains of autonomic dysregulation. Median score was 7 out of 10 (range 4-9).
Conclusions
The diagnostic criteria for HS are not sufficient to recognize autonomic dysfunction due to hypothalamic dysfunction in ROHHAD syndrome. Our add-on score may help in early recognition and follow-up in ROHHAD syndrome and other causes of hypothalamic syndrome.

JOINT2113

Decoding insulinomas: clinical insights and treatment pathways

Roxana-Andreea Danaila[1], Ana ?erban[1], Oana Ciobanu[1,2], Sorina Martin[1,2] & Simona Fica[1,2]
[1]Elias Hospital, Endocrinology, Diabetes, Nutrition, and Metabolic Diseases, Bucharest, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction
Insulinomas are rare, typically benign neuroendocrine tumors of the pancreas that cause hypoglycemia due to excessive insulin secretion. Malignancy can occur, particularly with local invasion or metastasis. These tumors are often associated with Multiple Endocrine Neoplasia type 1 (MEN 1), a genetic syndrome that predisposes individuals to various endocrine tumors. This work presents the experience of our department with a series of 12 insulinoma cases over a 22-year period, from 2003 to 2025.
Methods and results
The cohort consisted of 11 females and 1 male, yielding a female:male ratio of 11:1, with a median age at diagnosis of 38.58 years (range: 10–69 years). The diagnosis was confirmed through biochemical testing, such as measuring fasting plasma glucose, insulin and C-peptide levels, with a documented hypoglycemic episode in all patients. The tumors were localized using CT or MRI in 11 cases (91.7%), with intraoperative echographic exploration in one (8.3%). All patients underwent surgery, except for one who refused and is currently being treated with somatostatin analogs. The most common localization of insulinomas was in the pancreatic tail (58.3%), followed by the pancreatic head (25%), and multiple localizations in MEN 1 syndrome (16.7%). The benign insulinomas comprised 9 lesions (75%), with 7 classified as NET-G1 (58.3%) and 2 as NET-G2 (16.7%), both occurring in the context of MEN 1 syndrome. Three patients experienced recurrent hypoglycemic symptoms following surgery: one was lost to follow-up, while the other two, diagnosed with MEN 1 syndrome, are being managed with somatostatin analogs and diazoxide. It is important to note that, within the MEN 1 syndrome group, the mean

age at diagnosis was 18.6 years, with the youngest patient being 10, having a family history of MEN 1. These findings are consistent with the literature. We included 3 malignant insulinomas (25%). All presented with secondary hepatic metastases and were treated with chemoembolization, chemotherapy, or hepatic resection. One patient also had adrenal and kidney metastases receiving chemotherapy and PRRT. All patients with malignant insulinomas received treatment with somatostatin analogs.
Conclusion
Our findings are consistent with the literature, indicating that insulinomas are mostly benign, with a strong link to MEN 1 syndrome in younger patients. Malignant insulinomas, though rare, are frequently metastatic and require a comprehensive treatment strategy.
Key words
insulinoma, neuroendocrine tumors, insulin, multiple neuroendocrine neoplasia.

Neurohypophysitis in a pediatric patient with autoimmune hepatitis

Deborah De Guevara[1], Ana Feller[1], María Isabel Di Palma[1], Marta Ciaccio[1] & Mariana Aziz[1]
[1]Hospital de Pediatria J. *P* =Garrahan, Endocrinology, Ciudad Autonoma de Buenos Aires, Argentina

Introduction
Hypophysitis is a rare condition in pediatrics, considered an autoimmune phenomenon, with the most common form being lymphocytic hypophysitis. It frequently presents as central diabetes insipidus (CDI) or growth hormone deficiency (GHD). The diagnosis is clinical and radiological, though in some cases, a biopsy may be required to exclude other systemic or neoplastic diseases. The treatment includes the use of immunosuppressive therapy, with corticosteroids being the first-line therapy.
Case Description
A 15-year-old male patient was admitted for acute liver failure (abdominal pain, vomiting, and jaundice, associated with hyperbilirubinemia, hypertransaminasemia, hypoalbuminemia, and coagulopathy). Endocrinology was consulted due to the finding of hypernatremia. Upon directed questioning, he reported polydipsia, polyuria, and enuresis for 3 weeks. He denied headache or visual disturbances. On physical examination, his weight and height were in the 75-90th and 25th percentiles, respectively, with normal growth velocity, euthyroid status, Tanner stage G4 P4, and testes 15/15 cc. Given the suspicion of CDI, a water deprivation test was performed, confirming the diagnosis with a good response to oral desmopressin. Further studies were conducted, including hypothalamic-pituitary axis evaluation, with sufficient cortisol levels, low thyroid hormone levels consistent with euthyroid sick syndrome, growth hormone resistance (GH 11.1 ng/ml with undetectable IGF1 levels), and arrested puberty (LH 1.4 mUI/ml, FSH 2.16 mUI/ml, and Testosterone 1.12 ng/ml). Alpha-fetoprotein and β-hCG were negative, and skeletal radiographs were normal. A magnetic resonance imaging (MRI) scan revealed the absence of the spontaneously hyperintense signal in T1 of the neurohypophysis. No alterations were observed in the adenohypophysis or the pituitary stalk. During hospitalization, autoimmune hepatitis was confirmed with hypergammaglobulinemia, positive antinuclear antibody (ANA), and anti-smooth muscle antibody (ASMA), prompting the hepatology team to initiate methylprednisone 0.6 mg/kg/day orally. After 72 hours, desmopressin requirements decreased, and was finally discontinued after 10 days due to the development of hyponatremia. Normal sodium levels were maintained after 8 months of follow-up. Thyrotropin, somatotropin, and gonadotropin and testosterone levels normalized, considering previous alterations a transient phenomenon due to systemic disease.
Conclusions
We describe an adolescent who presented with CDI in the context of liver failure, later diagnosed with autoimmune hepatitis. The MRI only revealed the absence of the bright spot, without involvement of the pituitary stalk. Although this finding is present in 20% of the normal population, the clinical presentation, the association with autoimmune disease, and the excellent response to corticosteroid treatment increase the suspicion of a clinical picture compatible with neurohypophysitis.

Tolosa-Hunt syndrome?

Barbora Holá[1], Michal Krsek[1], David Netuka[2], Jiří Soukup[3], Manuela Vaněčková[4] & Václav Hána Jr[1]
[1]General University Hospital in Prague, III. internal clinic - clinic of endocrinology and metabolism, Praha, Czech Republic; [2]The Military University Hospital Prague, Department of Neurosurgery and Neurooncology, Praha, Czech Republic; [3]The Military University Hospital Prague, Department of Pathology, Praha, Czech Republic; [4]General University Hospital in Prague, Radiodiagnostic Clinic, Praha, Czech Republic

Introduction
Tolosa-Hunt syndrome (THS) represents a rare inflammatory disease of unknown etiology that affects the cavernous sinus, superior orbital fissure or orbital apex. It most commonly occurs in patients over the age of 40. The clinical presentation is characterized by unilateral headache and paresis of the oculomotor (III), trochlear (IV), and/or abducens (VI) cranial nerves, leading to painful ophthalmoplegia of the ocular muscles. Contrast-enhanced magnetic resonance imaging (MRI) usually reveals lesions in the cavernous sinus corresponding to inflammatory infiltrative changes. Histologically, granulomatous inflammation with fibroblast proliferation, lymphocyte infiltration, and the presence of plasma cells and giant cells is typically observed. Treatment primarily relies on glucocorticoids; however, in the case of recurrence, alternative immunosuppressive therapy or radiotherapy should be considered. THS is a diagnosis of exclusion.
Case Report
A 43-year-old female patient with a history of migrainous headache and an endocrinologically inactive pituitary adenoma noticed a worsening of her vision and diplopia in December 2023. Due to the sudden onset of symptoms and the known sellar lesion, she was urgently examined by an endocrinologist. On physical examination, there was a left-sided abducens nerve (VI) paresis and the development of convergent strabismus. MRI revealed progression of the sellar lesion, necessitating endoscopic transsphenoidal resection. Histological examination of the resected tissue confirmed a PitNET tumor of the corticotropic lineage (T-pit positive), with a secondary finding of granulomatous inflammation with necrosis of unclear etiology. Sarcoidosis, granulomatosis with polyangiitis, mycobacterial infections, and other etiologies were subsequently excluded. The diagnosis of THS was made of exclusion, and it was consistent with the pathological findings.
Therapy
Given the diagnosis of THS, intravenous corticosteroid therapy was initiated, followed by oral corticosteroid therapy, with gradual dose reduction. The patient's symptoms gradually improved with corticosteroid treatment.
Conclusions
The presented case corresponds to a combined finding of a PitNET and the rare Tolosa-Hunt syndrome.

JOINT1998

The iron key to adolescence: impact of chronic iron deficiency anemia on pubertal hormones, timing, and growth"

Dina Fawzy[1], Shaymaa Elsayed[1], Ashraf Soliman[2], Ahmed Elawwa[1], Fawzia Alyafei[2], Nada Alaaraj[2] & Noor Hamed[2]
[1]Pediatric Endocrinology and Diabetology Unit, Alexandria University, Pediatric Endocrinology and Diabetology Uni, Alexandria, Egypt; [2]Department of Pediatrics, Hamad General Hospital, Doha, Qatar

Background
Iron deficiency anemia (IDA) is a common nutritional deficiency worldwide, particularly among adolescents due to increased iron requirements during periods of rapid growth and physiological changes. Adolescence is a critical period marked by pubertal development, hormonal changes, and the pubertal growth spurt, all of which may be adversely affected by chronic IDA.
Objective
To examine the impact of chronic IDA on pubertal hormones, pubertal timing, and the pubertal growth spurt, drawing on research findings from 2000 to 2024.
Methods
A literature review was conducted to identify studies focusing on the relationship between chronic IDA and pubertal hormones and growth. Data from over 20 studies were synthesized into a structured table, including author, year, patient characteristics, interventions, and outcomes.
Results
1. Hormonal Impact: Chronic IDA suppresses gonadotropin-releasing hormone (GnRH) secretion, leading to reduced levels of luteinizing hormone (LH) and follicle-stimulating hormone (FSH). This results in lower estradiol in females and testosterone in males, delaying pubertal progression (Beard *et al*., The Journal of Nutrition, 2000).

2. Timing of Puberty: Adolescents with chronic IDA experienced delayed onset of puberty compared to peers with normal iron levels. Female adolescents were particularly affected due to menstrual blood loss (Iron Deficiency in Adolescence, The Journal of Pediatrics, 2017).
3. Pubertal Growth Spurt: IDA was associated with reduced growth velocity and impaired attainment of peak height during the pubertal growth spurt. This was attributed to diminished oxygen transport capacity and decreased energy metabolism, critical for growth processes (Santos *et al*., Journal of Human Growth and Development, 2012).
4. Intervention Outcomes: Iron supplementation was effective in restoring hormonal balance, improving growth velocity, and normalizing the timing of puberty. Early detection and treatment were emphasized for optimal outcomes (Iron Deficiency Anemia in Children, Johns Hopkins Medicine, 2024).
Conclusion
Chronic IDA during adolescence has profound implications for pubertal development, including disruptions in LH, FSH, estradiol, and testosterone levels, leading to delayed puberty and reduced growth velocity. Addressing IDA through early diagnosis and effective intervention is crucial to ensure normal growth and development during this critical period. Further research is needed to explore the long-term implications of IDA on reproductive and overall health.

Osilodrostat use in severe pediatric cushing's syndrome: short term outcomes in a case of pituitary adenoma

Alessandro Barbato[1,2], Giulia Del Medico[1,2], Gaia Varriale[2], Alessio Rossi[1,2], Laura Corbelli[1,2], Luca Manetti[3], Carlo Urbani[3], Giovanna Cristella[4], Mirko Scagnet[5], Nicolò Chiti[2] & Stefano Stagi[1,2]
[1]University of Florence, Department of Health Sciences, Florence, Italy; [2]Meyer Children's Hospital IRCCS, Auxo-endocrinology Unit, Florence, Italy; [3]University of Pisa, Department of Clinical and Experimental Medicine, Section of Endocrinology, Pisa, Italy; [4]IRCCS Don Carlo Gnocchi Foundation, Florence, Italy; [5]Meyer Children's Hospital IRCCS, Pediatric Neurosurgery, Florence, Italy

Background
Osilodrostat is an inhibitor of steroidogenesis approved for treatment of Cushing's disease in adults. It acts against 11β-hydroxylase (CYP11B1) which catalyzes the last step in cortisol synthesis. A trial in the pediatric population is ongoing to assess its pharmacodynamics, pharmacokinetics and tolerability (NCT03708900) but data about its efficacy in pediatric Cushing's disease are lacking.
Case presentation
A 10-years-9months old boy was transferred to the Intensive care Unit (ICU) of our center for refractory hypokalemia and sinus bradycardia with U waves. Upon clinical examination he presented facies lunaris, acne, central obesity and striae rubrae. Laboratory tests showed ACTH 139.7ng/l,serum cortisol 118 µg/dl (2.4-15), urinary free cortisol (UFC) 45 585.2 nmol/24h (upper reference range, URR, 124) at the first 24 h urine collection and 21 877.5 on the second collection. Considering UFC, Brain MRI was performed and revealed a hypophyseal mass: diagnosis of Cushing's disease was confirmed. Surgery to remove the hypophyseal adenoma was performed but it was complicated by meningitis requiring antibiotic therapy and a further period of recovery in ICU. Despite initial reduction, both ACTH and cortisol progressively increased up to 969 ng/lfor the former and 149 µg/dl for the latter, within three weeks after surgery. After 24 hours of treatment with Metyrapone, Osilodrostat was started at a dose of 1 mg twice daily. Due to swallowing issues, the tablets had to be shredded. After two weeks of treatment with Osilodrostat, UFC was within the URR with serum cortisol 53.8 µg/dl and ACTH 134.7 ng/L. One month later, with a dose of 1 mg + 1.5 mg, serum cortisol remained at 53 µg/dl. After three months, UFC was 179.1 µg/24h, slightly above the URR (176). PET scan using gallium-DOTATATE confirmed a residual pituitary adenoma, suspected due to lack of laboratory tests after surgery. No adverse events from Osilodrostat were observed.
Discussion
We described a case of pediatric Cushing's disease with recurrence after surgery, which demonstrated a laboratory response to Osilodrostat. This outcome was achieved starting with the minimal dose approved for adults in Europe, then increased by 0.5 mg (2.5 mg/day). Treatment was effective despite the need of shredding the coated tablets. Further studies are required to confirm the efficacy of Osilodrostat in pediatric patients to widen the therapeutic spectrum of Cushing's disease in this age group.

Pituitary abscess as a rare cause of multi-hormonal pituitary insufficiency and vasopressin deficiency (AVP-D, diabetes insipidus)

Jagoda Alicja Rogowska[1,2], Izabella Czajka-Oraniec[1], Jacek Kunicki[3] & Wojciech Zgliczyński[1]
[1]Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]Doctoral School of Translational Medicine, Centre of Postgraduate Medical Education, Warsaw, Poland; [3]Department of Neurosurgery, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

We present a case of a 39-year-old immunocompetent woman who developed a purulent pituitary infection, most likely secondary to recurrent sinusitis, that led to anterior pituitary insufficiency and vasopressin deficiency (AVP-D). The first symptoms appeared nine months postpartum and included severe headaches, vomiting, secondary amenorrhea, polydipsia, and polyuria. Multi-hormonal pituitary insufficiency and AVP-D were diagnosed. Pituitary MRI revealed an enlarged pituitary gland with a well-demarcated solid-cystic lesion measuring 22×14×16 mm, causing expansion of the sella turcica. Due to the suspicion of a pituitary adenoma, the patient underwent transsphenoidal surgery. During the procedure, upon incision of the lesion's capsule, thick yellow purulent-like content was released. Histopathological examination revealed features of chronic inflammatory exacerbation with necrosis, likely originating from the abscess wall. However, the patient did not receive further treatment apart from hormone replacement, owing to no improvement in pituitary function. She was admitted to our Department a year after an initial surgery due to gradually worsening symptoms, including headaches, nasal obstruction, and olfactory disturbances. MRI revealed an extensive infiltration involving the enlarged pituitary gland and sphenoid sinus. Due to symptomatic progression a second transsphenoidal surgery was performed. Histopathological analysis again revealed an inflammatory infiltrate, and Staphylococcus aureus was cultured from the sample. Targeted antibiotic therapy was initiated. Follow-up MRI scans showed no recurrence of the focal lesion. Based on clinical presentation, MRI findings, and histopathological and microbiological results, a diagnosis of pituitary abscess, leading to permanent multi-hormonal pituitary insufficiency and AVP-D, was established.
Discussion
Pituitary inflammation is a rare disease. The most common type is lymphocytic hypophysitis, while bacterial pituitary infections are exceedingly rare. The most frequently reported symptoms include headache, vomiting, visual disturbances, and signs of anterior or posterior pituitary insufficiency. MRI imaging typically shows a symmetrically enlarged gland with homogeneous contrast enhancement. Additionally, the characteristic "bright spot" of the neurohypophysis in T1-weighted images is usually absent, and the pituitary stalk may appear thickened. In some cases, the MRI appearance may resemble a pituitary adenoma or cyst. The treatment of choice for autoimmune-related hypophysitis in patients with neurological symptoms (e.g., severe headaches, cranial nerve palsies, and visual disturbances) is high-dose glucocorticoid therapy. However, other etiologies, such as infectious causes—like in the presented patient—should also be considered, and treatment should be tailored accordingly. In bacterial pituitary infections, obtaining cultures and an antibiotic susceptibility profile is crucial for implementing targeted antibiotic therapy.

Background
Central precocious puberty (CPP) presents age-dependent diagnostic and therapeutic challenges. This study aims to analyze the clinical, laboratory, and radiological features of CPP across age clusters and evaluate their impact on treatment decisions.
Methods
A prospective multicenter study (2014-2024) analyzed 591 CPP patients from a Portuguese national database, stratified into three age clusters based on symptom onset: cluster I ($\leq$3 years), cluster II (4–6 years), and cluster III ($\geq$6.1 years). Clinical, hormonal, and treatment data were compared across clusters.
Results
CPP diagnoses increased markedly during 2020–2021, driven primarily by cluster III ($P = 0.003$), decreasing thereafter. Females were predominant in all clusters (539; 91%), although cluster III had 40 from the 52 males, there was no sex incidence significant difference among clusters. Secondary causes were more prevalent in cluster I (45%, $P < 0.001$). Weight-SDS, Height-SDS and BMI-SDS were similar among clusters. As expected, growth velocity was higher in cluster I ($P = 0.011$), while bone age advancement was significantly lower ($P < 0.001$). Basal LH and FSH levels were highest in cluster III ($P = 0.004$, $P = 0.009$), whereas stimulated FSH peaked in cluster I ($P < 0.001$) and stimulated LH peaked in all clusters. Stimulated LH/FSH ratio was lower on cluster I (p= 0.002) . IGF1 and IGF1-SDS were elevated across all clusters, with no significant age-related differences. Treatment duration was longer in cluster I (5.7$\pm$0.8 years, $P = 0.001$), however they ended treatment with younger bone age (10.8$\pm$1.9 years; $P = 0.019$). Despite these differences, age at menarche was similar across clusters and age of menarche 0.5$\pm$1.9 years earlier than their mothers.
Conclusion
Age clustering highlights critical differences in CPP presentation, influencing diagnostic and therapeutic approaches. Earlier treatment intervention, although associated with longer treatment duration, did not affect menarche timing. Future studies are needed to investigate the apparent influence of external factors, such as the COVID-19 pandemic, on CPP incidence.

Gastric neuroendocrine tumors: a case series

Ana Serban[1], Roxana Danaila[1], Oana Petre[1,2], Sorina Martin[1,2] & Simona Fica[1,2]
[1]Elias Emergency Hospital, Endocrinology, Diabetes and Nutrition, Bucharest, Romania; [2]University of Medicine and Pharmacy "Carol Davila" Bucharest, Endocrinology, Bucharest, Romania

Introduction
The aim of this work is to present our department's experience with gastric neuroendocrine tumors (gNETs). The series of cases is comprised of 12 patients diagnosed with gastric NETs over a period of 15 years, from 2010 to 2025. A female predominance was observed, with a female/male ratio of 3:1.
Methods and results
According to literature, there are three main categories of gNETs, defined by the underlying gastric pathology. In our cohort, there were 8 patients diagnosed with type 1 gastric NETs (66.7%), one patient with type 2 (8.33%) and 3 patients with sporadic type 3 gNETS (25%). Type 1 gNETs are characterized by elevated gastrin levels in the context of autoimmune atrophic gastritis. All 8 patients had positive anti-parietal cell antibodies, decreased levels of vitamin B12 and hypergastrinemia, as well as elevated levels of chromogranin A. The median age at diagnosis was 58.5 years and 5 patients (62.5%) are still undergoing regular follow-up at our clinic. The majority of our patients with type 1 gastric NETS (87.5%) had multiple infra-centimetric lesions, with indolent evolution throughout follow-up, without loco-regional lymphadenopathy or distant metastasis, which is similar with data from literature. One patient (12.5%) had a singular lesion of over 2 cm diameter, with hepatic metastases present at diagnosis and G2 grading (Ki67=8%), which responded favorably to somatostatin analogue therapy and is currently monitored at 6 months interval. Five patients (62.5%) had a G2 grading and 3 patients (37.5%) had G1 tumors. One patient was diagnosed with type 2 gastric NETs in the context of multiple endocrine neoplasia type 1 (MEN 1). The initial evaluation showed multiple infra-centimetric G2 tumors (Ki67=3%) and hypergastrinemia. The patient underwent total gastrectomy, with subsequent normalization of biochemical markers. We also included 3 patients with type 3 gastric NETs, all of whom had, at initial evaluation, large tumors of over 3 cm and metastases to the liver, lung or peritoneum. Two patients had G2 gastric NETs and one had a G3 tumor (Ki67=70%). All patients received chemotherapy.
Conclusion
Our results corresponded to data from larger studies. Gastric NETs consist of three subtypes with distinct behavior and treatment. The only type 2 case occurred in the context of MEN1 syndrome. Type 1 tumors had an indolent evolution, whereas the type three ones were sporadic, larger and aggressive.

Copeptin levels at baseline and in response to short-acting GLP-1 receptor agonists in patients with endogenous hyperinsulinaemic hypoglycaemia and healthy controls - a secondary analysis

Sarah Baumann[1,2], Svenja Leibnitz[1,2], Cihan Atila[1,2], Christina Romberg[2], Matthias Hepprich[2,3], Kwadwo Antwi[4], Emanuel Christ[1,2] & Mirjam Christ-Crain[1,2]
[1]University Hospital Basel, Department of Endocrinology, Basel, Switzerland; [2]University Hospital Basel, University of Basel, Department of Clinical Research, Basel, Switzerland; [3]Cantonal Hopsital Olten, Department of Endocrinology, Olten, Switzerland; [4]St. Claraspital, Department of Nuclear Medicine, Basel, Switzerland

Background
Acute hypoglycaemia is a recognized non-osmotic trigger for copeptin release, a surrogate marker for vasopressin. However, data on copeptin levels in individuals at risk of chronic hypoglycaemia remain scarce. Endogenous hyperinsulinaemic hypoglycaemia (EHH), characterized by inappropriate insulin secretion and intermittent chronic hypoglycaemia, provides a useful model for investigating copeptin dynamics in the context of chronic hypoglycaemia. Therefore, this study aimed at evaluating baseline copeptin levels and copeptin responses to acute hypoglycaemia induced by short-acting GLP-1 receptor agonists, comparing patients with confirmed EHH to healthy controls.
Methods
This is a secondary analysis of the previously completed, randomized, double-blind, cross-over, proof of principle FAST study (NCT04909333) in patients with confirmed EHH and age-, sex- and BMI-matched healthy controls at the University Hospital Basel. The primary objective was to investigate baseline copeptin levels and to assess the acute effect of exenatide-induced decrease in glucose on copeptin levels in both groups. Patients were randomly assigned to first receive a single dose with exenatide (10ug) or placebo (0.9% sodium chloride) intravenously, followed by the alternate treatment on a subsequent day. Healthy controls only received exenatide. Plasma copeptin levels were measured at baseline and 60 minutes after the infusion. Individuals reporting nausea were excluded from the analysis.
Results
This analysis included eight patients and eight healthy controls. The median [IQR] age was 40 [34, 45] years, 75% were male, and the BMI was 28.4 kg/m^2 [26.0, 30.4]. Baseline copeptin levels were significantly higher in patients with EHH (7.28 pmol/l[4.27, 10.05]) compared to healthy controls (3.21 pmol/l[2.69, 4.55]) ($P = 0.03$). Fifty percent of patients experienced hypoglycaemia within 30 to 45 minutes after exenatide, accompanied by a glucose nadir of 2.71 mmol/l[2.68, 2.75], resulting in a copeptin increase of +2.13 pmol/l[0.40, 3.72] in this subgroup. Compared to placebo, no hypoglycaemic episodes occurred and copeptin levels decreased by -1.42 pmol/l[-2.11, -0.71]). Healthy controls reached a glucose nadir of 3.45 mmol/l[3.17, 3.53] within 30 to 45 minutes after exenatide, resulting in no relevant copeptin increase of +0.34 pmol/l[-0.01, 0.86], and only one participant experienced hypoglycaemia.
Conclusions
Patients with risk of chronic intermittent hypoglycaemia exhibit significantly elevated baseline copeptin levels compared to healthy controls. Exenatide induced a more pronounced blood glucose decrease in patients, triggering a stronger copeptin response compared to healthy controls, without downregulation from chronic hypoglycaemic stress. These findings provide further insights into copeptin dynamics in both chronic and acute hypoglycaemic states.

Treatment-resistant gh-secreting pituitary adenoma in young patient harboring a variant somatic mutation of the gnas gene: a case report

Pakanut Pitupan[1], Prapai Dejkhamron[1] & Karn Wejaphikul[1]
[1]Chiang Mai university, Division of Endocrinology and Metabolism, Department of Pediatrics, Faculty of Medicine, Chiang Mai, Thailand

Background
Growth hormone (GH)-secreting pituitary adenomas are rare in children. Surgical removal is the first-line treatment, while persistent disease may require long-

acting somatostatin receptor ligands (SRLs), with or without dopamine agonists. This study presents a pediatric case resistant to multiple transsphenoidal surgeries, first- and second-generation SRLs, and bromocriptine therapy.
Method
Clinical data were reviewed, and whole-exome sequencing (WES) was performed on peripheral blood leukocytes and tumor tissue.
Results
A 12-year-old girl presented with tall stature since age five, along with headaches and blurred vision. She denied galactorrhea, polyuria, or polydipsia. Examination revealed a height of 172 cm (+3.43 SDS), mid-parental height of 157.5 cm, weight of 84 kg (+4.56 SDS), enlarged hands and feet, bitemporal hemianopia, and Tanner stage V for breast and pubic hair. Laboratory tests showed elevated IGF-1 (721 ng/ml), non-suppressible GH (>40 ng/ml), and prolactin 41.3 ng/ml (3-24). Other hormone levels were within normal ranges (FT4 1.06 ng/dl (0.98-1.63), TSH 1.09 μIU/ml (0.51-4.30), stimulated cortisol 20.2 μg/dl, LH 3.88 IU/l,FSH 4.46 IU/l,estradiol 38.4 pg/ml). Bone age was 15 years. Brain MRI revealed a 2.1×2.6×2.4 cm sellar and suprasellar mass encasing the internal carotid artery and extending into the cavernous sinus, consistent with a GH-producing pituitary macroadenoma. The patient underwent craniotomy, with histopathology confirming a GH-positive pituitary adenoma. WES identified a heterozygous missense c.2530C>T (p.Arg844Cys) variant in the *GNAS* gene in tumor tissue, absent in leukocytes, suggesting a somatic mutation. Three months post-surgery, GH remained elevated (nadir 30.8 ng/ml) with IGF-1 at 617 ng/ml, and a residual tumor (0.76×0.84 cm) was noted. A second transsphenoidal surgery and monthly octreotide LAR (20–60 mg) failed to achieve biochemical control, with a nadir GH of 5.42 ng/ml and IGF-1 of 602 ng/ml. Pasireotide LAR and bromocriptine were administered, but GH levels fluctuated between 1.79–7.15 ng/ml and IGF-1 remained at 555–575 ng/ml. At ages 16 and 17, the patient underwent a third and fourth surgery, but GH levels remained uncontrolled (nadir 6.86 ng/ml). Pegvisomant was considered but unavailable. She is now scheduled for proton radiation therapy.
Conclusions
We report a treatment-resistant GH-secreting pituitary adenoma in a pediatric patient harboring a somatic GNAS mutation. Managing such cases remains challenging, particularly in children. Stereotactic or proton radiotherapy should be considered when surgery and medical therapy fail to achieve biochemical control.

Assessment of NF-κB levels in acromegalic patients with hepatosteatosis

Hatice Ozisik[1], Tarik Inci[2], Adil Bahadir[3], Nazlican Seren[4], Su Ozgur[5], Erhan Canbay[4], Gaye Hamarat[6], Gökçen Ünal Kocabaş[1], Nur Selvi Gunel[6], Eser Yildirim Sozmen[4] & Banu Sarer Yurekli[1]
[1]Ege University, Endocrinology, İzmir, Türkiye; [2]Ege University, Internal Medicine, İzmir, Türkiye; [3]Ege University, Faculty of Medicine, İzmir, Türkiye; [4]Ege University, Medical Biochemistry, İzmir, Türkiye; [5]Ege University, Biostatistics and Medical Informatics, İzmir, Türkiye; [6]Ege University, Medical Biology, İzmir, Türkiye

Introduction
Acromegaly is a disorder characterized by excessive secretion of growth hormone (GH), leading to increased insulin-like growth factor-1 (IGF-1) levels. Nonalcoholic fatty liver disease (NAFLD), a significant global health concern, is considered the hepatic manifestation of metabolic syndrome and may progress to fibrosis, cirrhosis, or hepatocellular carcinoma. The noninvasive test fibrosis-4 (FIB-4) score are the commonly used and recommended hepatic fibrosis scores for screening liver fibrosis. FIB-4 upper cut-off of < 1.3 suggests better diagnostic accuracy for predicting NAFLD. Nuclear factor kappa B (NF-κB) activation may contribute to insulin resistance and metabolic syndrome-related pathologies, including hepatic steatosis in acromegalic patients. This study aims to investigate the inflammatory processes in acromegalic patients with hepatosteatosis and controls to determine NF-κB levels in both conditions.
Methods
A total of thirty participants, including sixteen acromegalic patients and fourteen controls, will be included. We obtained demographic data, hormonal and metabolic parameters, and abdomen ultrasonography (USG) reports. NF-κB levels were measured using ELISA.
Results
The median age and gender distribution of the study participants were similar across groups ($P > 0.05$). Among the clinical parameters, there were significant differences in the mean values of fasting insulin ($P = 0.002$), GH ($P = 0.049$), IGF-1 ($P < 0.001$), and FIB-4 ($P = 0.001$), with higher values observed in acromegaly patients. In univariate logistic regression analysis, fasting insulin was found to increase the risk of acromegaly (O $r = 2.76$; 95% CI [1.032-7.380]), and FIB-4 was also identified as a risk factor ($P = 0.009$). In the multivariate analysis, FIB-4 remained a significant risk factor ($P = 0.009$). ROC analysis for distinguishing between acromegaly and control group revealed that fasting insulin had an AUC of 0.833 (sensitivity=68%, specificity=92%), while FIB-4 had an AUC of 0.821 (sensitivity=76%, specificity=93%). In sensitivity analyses, the acromegaly group was evaluated as controlled and uncontrolled. When comparing the mean FIB-4 values among the three groups, a significant difference was observed ($P = 0.005$). Post-hoc comparisons revealed significant differences between the healthy and controlled acromegaly groups ($P < 0.001$) as well as between the healthy and uncontrolled acromegaly groups ($P < 0.001$). The median NFKB levels were similar between the healthy and acromegaly groups ($P = 0.339$). No significant difference was detected when comparing NFKB medians among the three groups ($P = 0.539$).
Conclusion
This study is the first study to investigate NF-κB levels in acromegalic patients with hepatosteatosis, highlighting its potential role in metabolic dysfunction and hepatic inflammation. FIB-4 was identified as a risk factor to increase the risk of acromegaly. No significant difference was detected when comparing NFKB.

JOINT1206 Assessment of liver steatosis and fibrosis in acromegaly

Tugce Apaydin[1], Haluk Tarik Kani[2], Caglayan Keklikkiran[3], Yusuf Yilmaz[3] & Dilek Gogas Yavuz[3]
[1]Marmara University School of Medicine, Alanya Training Hospital, Endocrinology and Metabolism, Istanbul, Türkiye; [2]Marmara University School of Medicine, Gastroenterology, Istanbul, Türkiye; [3]Marmara University School of Medicine, Rize Recep Tayyip Erdogan University School of Medicine, Gastroenterology, Istanbul, Türkiye

Introduction
Growth hormone (GH) has been shown to play a protective role against liver steatosis by reducing visceral adipose tissue. Liver fibrosis has been observed in cases of GH resistance and impairment of GH signaling pathways. In this study, we aimed to evaluate liver steatosis and liver fibrosis in patients with acromegaly.
Materials and Methods
This cross-sectional study included 58 patients diagnosed with acromegaly, followed up at the endocrinology outpatient clinic of Marmara University Hospital, along with 79 age-, sex-, and BMI-matched control patients. Hepatic steatosis and liver fibrosis were evaluated using controlled attenuation parameter (CAP) and liver stiffness measurements (LSM) via FibroScan, performed by a single experienced operator. Increased hepatic steatosis was defined as a CAP > 260 dB/m (>34% fat), and increased liver fibrosis was defined as an LSM ≥8 kPa (F ≥2).
Results
The acromegaly and control groups showed a similar distribution in terms of age, gender, body mass index (BMI), and the prevalence of diabetes, hypertension, and hyperlipidemia. No significant differences were observed between the groups regarding fasting blood glucose (FBG), LDL cholesterol levels, or liver function tests ($P > 0.05$). The CAP score, a marker of hepatic steatosis, was significantly lower in the acromegaly group compared to the control group (241.8 ± 50.0 dB/m vs. 289.8 ± 65.3 dB/m, $P < 0.001$). Similarly, the LSM score, used to assess hepatic fibrosis, was lower in the acromegaly group compared to controls (4.7 ± 1.4 kPa vs. 6.4 ± 4.5 kPa, $P = 0.007$). Moderate-to-severe hepatic steatosis was present in 36.2% of the acromegaly patients and 60.7% of the control group ($P = 0.005$). Fibrosis stage F2 or higher was detected in 5.1% of patients with acromegaly, compared to 17.7% of the control group ($P = 0.035$). A negative correlation was found between CAP score and GH levels (r: -0.311, $P = 0.017$), while positive correlations were identified between CAP score and FBG, BMI, and waist circumference (r: 0.298, $P = 0.020$; r: 0.447, $P < 0.001$; and r: 0.447, $P = 0.001$, respectively). Positive correlations were observed between LSM and both age and BMI (r: 0.400, $P = 0.001$; r: 0.540, $P < 0.001$).
Discussion
Hepatic steatosis and hepatic fibrosis were observed less frequently in patients with acromegaly compared to the control group. A negative correlation was identified between hepatic steatosis and GH levels. Elevated GH may have a potential protective role against fatty liver development in acromegaly patients, regardless of comorbid conditions such as diabetes and hyperlipidemia, which are major contributors to fatty liver disease.

Natural history and clinical behaviour of non-operated rathke's cleft cysts: a single-centre retrospective review

Trevor Tam[1,2], Francesca Swords[1], Ketan Dhatariya[1,2] & Rupa Ahluwalia[1]
[1]Norfolk and Norwich University Hospital, Norwich, United Kingdom; [2]University of East Anglia, Norwich, United Kingdom

Background
Rathke's cleft cysts (RCCs) are benign, sellar or suprasellar cystic lesions of the pituitary gland. While frequently incidental, they can cause symptoms due to mass effects (headaches and/or visual disturbances) or due to endocrine dysfunction. Optimal management remains debated. This review examines the natural history of non-operated RCCs (radiological and endocrine progression) in a single-centre UK cohort.
Methods
Single-centre retrospective review of non-operated RCCs that were conservatively managed between 1/1/2021 and 31/12/2024. Data collection- demographics, presenting symptoms, endocrine function, radiological findings, follow-up outcomes.
Results
45 patients identified (median age 54 years at diagnosis, IQR 32 – 67 years, range 14 – 88 years). 31/45 (68.9%) diagnosed incidentally. Most common presenting symptom amongst non-incidental cases: headache (10/14, 71.4%). At diagnosis, 42/45 (93.3%) eupituitary. 3/45 (6.7%): hypopituitary (low growth hormone levels, arginine vasopressin deficiency, panhypopituitary with raised prolactin). At diagnosis, median cyst size (maximal diameter) 6 mm (IQR 5 –9 mm). All had full visual fields to confrontation. 1st follow-up: 28/45 (25 eupituitary, 3 endocrine deficit) (62.2%) received follow-up imaging. Median interval to 1st follow-up- 12 months (IQR 7.5 – 12 months, range 6 – 48 months). 17/45 (37.8%)- waiting for 1st follow-up scan. Biochemical and visual field findings: At 1st follow-up, 25 eupituitary patients at diagnosis, none developed new endocrine deficits. In the 3 patients with endocrine deficits at diagnosis, deficits remained the same. All patients (28/28)- normal visual fields. Subsequent follow-up: Median interval to most recent follow-up- 24 months (IQR 12.75 – 58.50 months, range 7 – 126 months). Biochemical and visual field findings: At most recent follow-up, 25 eupituitary patients at diagnosis, none developed new endocrine deficits. In the 3 patients with endocrine deficits at diagnosis, deficits remained the same. 27/28 (96.4%) normal visual fields, 1/28 (3.6%)- left inferotemporal visual field defect secondary to haemorrhage at 15 months after diagnosis.
Conclusion
The majority of RCCs in our cohort remained stable or regressed, with a low risk of developing new endocrine deficits. Conservative management appears safe, with routine hormonal screening potentially unnecessary in asymptomatic patients. We propose a patient-initiated follow-up based on symptomatic presentation instead of routine screening of non-operated RCCs. Future retrospective and prospective studies with longer periods of monitoring are warranted to further refine surveillance strategies.

Table 1. Radiological findings:.

No. of patients	Outcome
24 (85.7%)	Stable

Relationship between disease severity and puberty status in pediatric systemic lupus erythematosus (SLE) patients

Harjoedi Tjahjono[1,2], Irfan Salim[1], Fadilah Mutaqin[1] & Ahmad Ta'qiuddin[1]
[1]Saiful Anwar Hospital, Brawijaya University, Pedatrics Department, Malang, East Java, Indonesia, Japan; [2]RSUD Dr. SAIFUL ANWAR PROVINSI JAWA TIMUR, Pediatrics, Pediatric Endocrinology, Malang, Indonesia

Background
Systemic lupus erythematosus (SLE) is a disease that spreads all over the world. The incidence of SLE in children is 10-20 cases per 100,000 children. Compared with SLE in adults, SLE in children tends to be more severe, requires more intensive care and a higher mortality rate. Growth failure and delayed puberty can also be an effect of SLE in children, caused by severe disease activity and long-term disease duration that can affect the whole body.
Objective
The aim is to understand the effect of systemic lupus erythematosus on pubertal growth and development so that it can help doctors to improve efforts to control systemic lupus erythematosus.
Methods
Total respondents were 23 pediatric patients diagnosed with SLE at dr Saiful Anwar Hospital. Data for each variable studied was obtained through medical records. Puberty status using the Tanner scale, the level of LES disease activity was measured by the SLEDAI Score.
Results
The results showed that the majority of respondents had very high disease activity (39.1%), high disease activity (30.4%), moderate disease activity (21.7%), and mild disease activity (8.7%). Puberty status was found (87%) of normal pubertal development of children and (13%) of delayed pubertal development of children. The results of data analysis using logistic regression showed that there was no relationship between the severity of SLE and the pubertal status ($P = 0.249$) of children at dr. Saiful Anwar Hospital.
Conclusion
The conclusion is that there is no relationship between the severity of SLE disease and the pubertal status ($P = 0.249$) of children in dr. Saiful Anwar Hospital.
Keywords
systemic lupus erythematosus, puberty, children, SLEDAI score.

Triple hormone secreting pituitary macroadenoma: a rare cas

Nora Boutatss[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]UHC Ibn Rochd, Department of Endocrinology and Metabolic Diseases Ibn Rochd University Hospital - Casablanca, Morocco Laboratory of Clinical Neurosciences and Mental Health Faculty of Medicine and Pharmacy - Hassan II University - Casablanca, Morocco

Introduction
Pituitary adenomas are classified based on their hormonal secretion, with prolactinomas, somatotropinomas, and corticotropinomas being the most common. However, pituitary adenomas secreting three hormones are extremely rare and often manifest as a complex endocrine syndrome. We report a unique case of a triple-secreting pituitary macroadenoma (GH, PRL, ACTH) in a young woman, presenting solely with isolated galactorrhea, without signs of acromegaly or Cushing's syndrome.
Case Presentation
A 25-year-old woman presented with a six-year history of bilateral galactorrhea, which later progressed to secondary amenorrhea and thyrotropic insufficiency. She had no headaches, visual disturbances, or symptoms suggestive of acromegaly or hypercortisolism. Clinical examination confirmed bilateral galactorrhea, with no facial dysmorphism, acral enlargement, centripetal obesity, or easy bruising. Laboratory tests revealed hyperprolactinemia (>250 ng/ml, normal: 5-35 ng/ml), a normal IGF-1 level, and a normal 24-hour urinary free cortisol level. Thyroid function tests confirmed central hypothyroidism, with normal gonadotropin levels. Brain MRI revealed a sellar and suprasellar pituitary macroadenoma ($25 \times 14 \times 20$ mm) with optic chiasm compression and lateral extension into the cavernous sinuses, exhibiting heterogeneous gadolinium enhancement. Histopathological analysis confirmed a pituitary adenoma with strong immunohistochemical positivity for GH, prolactin, and ACTH, with negative staining for TSH and gonadotropins.
Discussion and Conclusions
Triple-hormone-secreting pituitary adenomas are extremely rare and usually present with overt clinical signs of hormone hypersecretion. However, in this case, the patient exhibited only galactorrhea and secondary amenorrhea, despite histological evidence of GH and ACTH hypersecretion, suggesting silent or subclinical hormonal overproduction. This case highlights the importance of a comprehensive endocrine evaluation, as some patients may develop delayed manifestations. First-line treatment consists of transsphenoidal surgery, aiming to reduce tumor mass and normalize hormone secretion, followed by dopamine agonist therapy for hyperprolactinemia and levothyroxine replacement for thyrotropic insufficiency. Long-term endocrine follow-up is essential to detect potential late-onset acromegaly or Cushing's syndrome, emphasizing the need for a multidisciplinary approach involving endocrinologists, neurosurgeons, and radiologists to optimize the patient's prognosis.

Objective
This real-world study (RWS) aims to evaluate the effectiveness, safety, and treatment patterns of lanreotide autogel (LAN) in Chinese patients with acromegaly. The abstract summarizes only baseline data.
Methods
This multicenter, prospective, observational real-world study was conducted across 12 sites in China. A total of 127 patients with acromegaly were planned to enroll based on key inclusion criteria: serum insulin-like growth factor-1 (IGF-1) levels above the upper limit of normal (ULN) and fasting growth hormone (GH) levels >2.5 μg/l,untreated with LAN. Fasting GH and IGF-1 levels, and LAN administration details (dose titration and interval adjustments), were collected at baseline (last before index), 3, 6, and 12 months after LAN initiation. Adverse events (AEs) and special situations (e.g., pregnancy, overdose) were monitored throughout the study. The baseline data include demographic, clinical characteristics (time since acromegaly first diagnosis, size of pituitary tumor, symptoms, comorbidities, etc.), and prior treatments for acromegaly (treatment types, prior medications, etc.). The primary endpoint is defined as the proportion of patients achieving biochemical control (fasting GH level ≤ 2.5 μg/land IGF-1 return to normal range adjusted to age category) at 12 months.
Results
A total of 129 patients were enrolled and treated, of whom 75 (58.1%) were female. At baseline, patients had mean (SD) age of 43.3 (13.4) years, body mass index of 25.97 (4.11) kg/m^2, and fasting GH (μg/l)and IGF-1 (xULN) of 22.30 (49.15) and 2.10 (1.75), respectively. The median (95% CI) time to acromegaly first diagnosis was 1.1 (0.8, 1.7) years. Pituitary tumors were observed in 97/127 (76.4%) patients at baseline, with 50 (39.4%) macroadenomas and 29 (22.8%) microadenomas. Clinical symptoms were present in 112 (86.8%) patients (soft tissue swelling (63.6%), headache (39.5%), joint pain (29.5%), fatigue (27.1%), and excessive sweating (20.9%)). Comorbidities were observed in 81 (62.8%) patients (altered carbohydrate metabolism (27.1%), sleep apnea (26.4%), hypopituitarism (25.6%), hypertension (20.2%), and heart disease (12.4%)). 66.7% of the patients had undergone pituitary transsphenoidal surgery, 31.0% had radiotherapy, and 41.9% had prior medications (Octreotide LAR, 27.1%; Bromocriptine, 10.1%; and Cabergoline, 3.9%). At the first LAN prescription, 91.5% of patients received a 28-day dosing schedule, 48.8% were prescribed 90 mg and 51.2% for 120 mg.
Conclusions
This interim analysis shows the study mainly included postoperative patients with pituitary macroadenomas and multiple comorbidities. LAN was administered at doses of 90 mg and 120 mg half each, predominately once every 28 days in Chinese patients with acromegaly.

Misdiagnosed pituitary adenoma in a reproductive age woman

Natia Shonia[1], Nino Zavrashvili[1] & Mariam Orjonikidze[1]
[1]Tbilisi Institute of Medicine, David Tvildiani Medical University, Tbilisi, Georgia

Introduction
Acromegaly is a rare condition predominantly caused by a growth hormone (GH)-secreting pituitary adenoma driving excess secretion of insulin-like growth factor-1 (IGF-1). Multitude of manifestations have been associated with chronic GH excess, including cardiovascular, pulmonary, neoplastic, endocrine, metabolic and musculoskeletal comorbidities. The diagnosis of acromegaly is confirmed on biochemical grounds. Pituitary magnetic resonance imaging is advised in patients to identify an underlying pituitary adenoma. Transsphenoidal pituitary surgery is generally first-line therapy for patients with acromegaly. Medical therapies can be recommended to patients with persistent disease. Radiation therapy is usually a third-line option.
Case Report
We present a case of 33 y/o female first diagnosed with pituitary macroadenoma, hyperprolactinemia at the age of 20. Additional pituitary hormonal work-up was not performed at that time. Treatment with dopamine agonist (cabergoline) was initiated. 5 years after diagnosis, patient was evaluated by another endocrinologist due to increasing headaches, lightheadedness, acral and facial features of acromegaly (skin thickening, changes to facial symmetry, increased shoe size). Head MRI and additional laboratory work-up revealed growth of pituitary adenoma and increased levels of IGF-1. Patient was diagnosed with acromegaly and transsphenoidal surgery was performed which led to slightly decreased levels of IGF-1. Repeated MRI scan performed a year later, revealed residual tissue. Repeat TSS was performed in Germany a year later due to residual intrasellar disease following initial surgery. IGF-1 levels normalized after surgery and patient was being monitored. Elevated IGF-1 levels were not demonstrated until 2022. Patient was advised to initiate treatment with somatostatin analogs, which she declined, alternatively, due to modest elevations of serum IGF-1 and mild signs and symptoms of GH excess, off label use of dopamine agonist –cabergoline was offered. Most recent MRI does not show evidence of residual tissue. Patient continues DA therapy, currently her IGF-1 levels are well under control. Patient is being counseled and monitored for recurrence and associated comorbidities.
Conclusion
A high index of suspicion is needed to minimize delays in diagnosis of acromegaly. Goals of treatment include normalization of GH secretion or (at least) GH action as indicated by a normal IGF-1 level as well as by resolution of tumor-induced mass effects, acromegaly-related symptoms, and associated comorbidities, all aiming at mitigating excess mortality while preserving normal pituitary function.

Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy

Background
Pituitary metastases are a rare pathological finding. This case series aims to evaluate certain variables in patients with pituitary metastases.
Methods
We performed a retrospective analysis of pituitary metastasis patients who came to our center from 2018 to 2023. All patients underwent pituitary MRI and the diagnosis of pituitary metastasis was confirmed by histological examination.
Results
We identified 10 patients of whom 7 were female and 3 male, with a mean age of 56.7 years. The histological features of the neoplasms found were: breast carcinoma (2), neuroendocrine tumors of probable lung origin (2), adnexal carcinoma (1), gastrointestinal carcinoma (1), melanoma (1), small cell lung carcinoma (1), thyroid carcinoma (1), diffuse large cell non-Hodgkin's lymphoma (1). Visual disturbances were the most frequent onset symptom (30%). A

prolactin elevation was found in one patient. All patients underwent transsphenoidal surgery to debulk, reduce and/or resolve symptoms and restore proper hormone secretion. In 60% of the patients residual disease was found at postoperative radiological control. In the postoperative period, 70% of patients had a deficit in the secretion of pituitary hormones: anterior hypopituitarism (4 patients) and diabetes insipidus (3 patients) were the most frequent. Only 3 patients (30%) had no deficits in hormone secretion after undergoing transsphenoidal surgery. In 30% of the patients, the pituitary gland was identified as the first site of metastasis. In one patient, suffering from neuroendocrine carcinoma, the primary neoplasm was not found.
Conclusion
Pituitary metastases are characterized by great heterogeneity in clinical presentation, hormonal deficits, and origin of the primary neoplasm. Generally, this type of lesion is treated as an adenoma; only after the lesion is removed and histological examination is performed can it diagnose pituitary metastasis. An interesting finding from this series is that in 3 patients the pituitary gland was identified as the primary site of metastasis, with no evidence of metastatic disease in other districts. Surgery represents the first line of therapy. The rate of residual or recurrence of disease after surgery remains considerable.

Neurocognitive and neuropsychological assessment in the acromegalic patient: correlation with clinical, biochemical and prognostic features

Simone Antonio De Sanctis[1], Ginevra Mongelli[1], Antonella Giampietro[1], Pier Paolo Mattogno[2], Liverana Lauretti[2], Antonio Bianchi[1], Sabrina Chiloiro[1] & Alfredo Pontecorvi[1]
[1]Division of Endocrinology and Metabolism Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario A. Gemelli, IRCCS, Endocrinology and Diabetology, ROMA, Italy; [2]Neurosurgery Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario A. Gemelli, IRCCS, Neurosurgery, Roma, Italy

Acromegaly is a rare disease caused by the presence of a sporadic growth hormone (GH)-secreting pituitary/neuroendocrine adenoma. Patients with acromegaly progressively go through disfigurement of somatic features and relevant systemic manifestations, induced by chronic exposure to growth hormone. In this context of multimorbidity, it is also necessary to assess the cognitive and neuropsychological picture, which is often compromised. In order to perform a comprehensive assessment of cognitive performance and neuropsychological profile in a cohort of acromegalic patients and investigate their correlation with clinical, biochemical and prognostic features, a single-center prospective study was conducted at our Institution in 2023. The population examined consisted of 50 acromegalic patients, 27 women (54%) and 23 men (46%), being treated at the Gemelli Polyclinic Pituitary Outpatient Clinic. All of them were subjected to various neuropsychological questionnaires and tests on reported quality of life. In addition, they were administered neurocognitive tests to the 7 patients in the cohort who were over 65 years old. The most prominent complaints found were fatigue (84%), irritability (82%), emotional changes (76%), work difficulties (70%), increased sensitivity to stress (68%), frustration (62%), physical pain (56%), decreased libido (56%), memory problems (52%) and sadness (50%). The results of the study showed that cognitive and neuropsychological disorders are present to a greater extent in patients with acromegaly than those found in the general population. These alterations were also correlated with independent factors such as age, gender, and the results of the AcroQoL questionnaire, thus allowing the identification of the categories of acromegalic patients at higher risk for neuropsychological disorders. In conclusion, it is essential, in taking care of the patient with acromegaly, to undertake a multidisciplinary diagnostic-therapeutic pathway that is able to take into account the peculiarities of the patient's neurocognitive and neuropsychological profile, with a view to best practice.

Objective
Bone metastases (BMs) are rare and late event in patients with neuroendocrine tumors (NETs). The aim of our study was to investigate determinants, clinical presentation and outcome of BMs in a large cohort of patients with NETs.
Methods
A retrospective, longitudinal case-control study was performed at two referral centers of Northern Italy (IRCCS Humanitas Research Hospital in Milan and S. Maria della Misericordia University Hospital in Udine). Three-hundred-fifty-two consecutive patients with either gastroenteropancreatic neuroendocrine tumors (GEP-NETs) or non-GEP-NETs were included: 52 patients with synchronous or metachronous BMs (case group) and 300 patients with metastatic disease without BMs (control group).
Results
Patients with BMs showed a higher prevalence of smoking habit (41.2% vs 21.8%, $P = 0.013$) and carcinoid syndrome (28.8% vs 5.7%, $P = 0.001$), as compared to controls. Cases had also higher levels of chromogranin A ($P=0.001$) , urinary 5-hydroxyindoleacetic acid ($P = 0.001$), parathyroid hormone ($P=0.023$) and alkaline phosphatase ($P = 0.018$) as compared to control group. Patients with BMs had more frequently lung NETs (19.2% vs 0.7%, p-value 0.001) and grade G2 and G3 tumors ($P = 0.012$ and $P = 0.01$, respectively), as compared to controls. During follow-up (median 4.33 years), a higher mortality rate was registered in the case group as compared to the controls (42.3% vs 4.0%, p-value 0.001).
Conclusions
BMs were more common in patients with lung NETs, G2-G3 grade and in those with carcinoid syndrome. BMs affected patients' prognosis, highlighting the importance of investigating and managing this condition in patients with NETs.

Endoscopic endonasal treatment in patients with crooke's cell adenomas

Barbara Buchalska[1], Jacek Kunicki[1] & Maria Maksymowicz[2]
[1]Maria Skłodowska-Curie National Research Institute of Oncology, Department of Neurosurgery, Warsaw, Poland; [2]Maria Skłodowska-Curie National Research Institute of Oncology, Department of Pathology, Warsaw, Poland

Introduction
Crooke's cell adenoma (CCA) is a rare subtype of pituitary adenoma (<1%). CCAs are usually invasive, may exhibit aggressive behavior, and often recur. Thus, the treatment of CCAs is difficult and might not result in a complete remission. The aim of this study was to assess characteristics of a group of patients with CCAs treated with endoscopic endonasal resections.
Material and Methods
The study is a retrospective analysis of a series of 18 patients (6 women and 12 men) treated from the 2015 to 2024 by the endoscopic transsphenoidal surgeries for CCAs. The mean age of the patients was 48.3 years (18-77 years), and the mean follow-up period was 5.3 years (0-11 years).
Results
Preoperatively 8 patients had visual function deterioration (44.4%), 8 patients had Cushing's disease (44.4%), 6 patients had hypopituitarism (33.3%), 4 patients had headaches (22.2%). Gross total resections were achieved in 6 out of 8 patients with Cushing's disease (75%), and in 7 out of 10 patients with silent adenomas (70%). Most patients (88.9%) had macroadenomas. Five patients (27.8%) had an intra-operative cerebrospinal fluid leak, and a reconstruction of the sella with a fat tissue graft. Postoperatively 75% of the patients showed varying improvement in visual field defects and visual acuity. The only complication was transient diabetes insipidus (DI) observed in 3 patients (16.7%). One patient progressed to pituitary carcinoma, had four subsequent resections, and eventually died. The remission of Cushing's disease was achieved in 6 patients after surgery (75%).

Conclusions
Endoscopic transsphenoidal treatment of patients with CCAs is safe and associated with a low complication rate. The patients are younger and have more resections than in usual pituitary adenomas.

AIP variants among adult patients with acromegaly

Anna Bogusławska[1], Maria Aleksandra Komisarz-Calik[1], Karol Ciszek[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland

Introduction
AIP variants are found in up to 40% of familial cases of acromegaly and gigantism, as well as in some sporadic cases, particularly those with early-onset disease. Patients with *AIP* variants often present with higher growth hormone (GH) levels. AIP variants are found in up to 40% of familial cases of acromegaly and gigantism, as well as in some sporadic cases, particularly those with early-onset disease. Patients with *AIP* variants often present with higher growth hormone (GH) levels with no difference in insulin growth factor 1 (IGF-1) level.
Objectives
We studied the prevalence of *AIP* variants in a cohort of unselected, consecutive adult patients with acromegaly from 2019 to 2024.
Materials and methods
A total of 134 patients (79 females, 55 males, age range 16-75 years) with somatotroph pituitary neuroendocrine tumor who were studied at the Jagiellonian University (Krakow), a tertiary referral center, were enrolled in this study. Genetic testing (Sanger Sequencing) was performed in all patients with acromegaly.
Results
Germline *AIP* variants were identified in eight patients including five missense variants, one three-nucleotide deletion. The specific variants observed were c.47G>A (p.Arg16His) in three patients, c.911G>A (p.Arg304Gln) in one female patient, c.235A>C (p.Thr79Pro) in one male patient, c.941G>C (p.Arg314Pro) in one male patient, c.811C>T (p.Arg271Trp) in one male patient, and c.742_744del (p.Tyr248del) in one female patient. The clinical significance of .47G>A and c.911G>A remains uncertain and is currently under discussion. The median age of symptom onset was 34 years (range: 14–71 years), while the median age at diagnosis was 39 years (range: 16–72 years). Most cases (7 out of 8) presented with macroadenomas, and six patients were not cured following surgery. Three patients harbored mix tumour (prolactin co-secretion). Additionally, 50% of *AIP* variant carriers met the criteria for familial isolated pituitary adenoma (FIPA).
Conclusions
This study show the prevalence of *AIP* variants among adult patients with acromegaly in Poland. Genetic testing in acromegaly should be considered to personalize and optimize the treatment of patients.

Granular cell tumor of the pituitary gland – an exceedingly rare diagnosis

Tânia Carvalho[1], Margarida Sobral[1], Sofia Lopes[1], Alice Monsanto[1], Gustavo Rodrigues[1], Joana Saraiva[1], Pedro Fonseca[1], Guerreiro Costa[1] & Leonor Gomes[1]
[1]Unidade Local de Saúde De Coimbra, Coimbra, Portugal

Introduction
Granular Cell Tumors (GCTs) are exceptionally rare neoplasms arising in the posterior lobe of the pituitary gland (or neurohypophysis). Typically benign and slow growing, these tumors may present with symptoms related to mass effect or hypopituitarism. Due to their nonspecific radiological features, they are often indistinguishable from other sellar lesions, with definitive diagnosis requiring histopathological confirmation. Here, we present a case of GCT with a four-year follow-up, contributing to the limited literature on this entity.
Case Report
A 78-year-old woman presented with insidious visual disturbances. Initial evaluation by ophthalmology revealed a diagnosis of cataracts, but there was no improvement after phacoemulsification surgery. Further assessment revealed bitemporal hemianopsia and cranial MRI identified a 17x15x12mm tumor with suprasellar extension compressing the optic chiasm and contacting with the internal carotid arteries. The lesion exhibited isointensity on T1-weighted imaging and diffuse contrast enhancement. Hormone evaluation revealed hypogonadotropic hypogonadism (FSH 5.1mUI/ml [RR>34], LH 1.2mUI/ml [RR>25]), low TSH (TSH 0.31uUI/ml [RR 0.40-4.00], FT4 1.0ng/dl [RR 0.7-1.5], under levothyroxine treatment), secondary adrenal insufficiency (cortisol 4.2ug/dl [RR 5-25], ACTH<5.0pg/ml [RR 9-52]) and a slight prolactin elevation (45.5ng/ml [RR 5.2-26.5]); IGF1 was normal (161ng/ml [RR 81-225]). Hydrocortisone replacement therapy was initiated. The patient underwent decompressive transsphenoidal surgery, achieving only partial resection of the lesion due to its proximity to critical structures and hypervascularity. Post-operatively, pituitary dysfunction worsened (FSH <1.0mUI/ml, LH <1.0mUI/ml, prolactin 2.4ng/ml, TSH <0.004uUI/ml, FT4 0.70ng/dl, cortisol 1.0ug/dl, ACTH<5.0pg/ml, GH <1.0mg/l,IGF1 39ng/ml). Histopathological examination documented a grade I CGT of the sellar region, with a Ki-67 index of 3%. Immunohistochemistry showed TTF-1 positivity and other pituitary hormone markers were negative. Postoperative imaging revealed a residual sellar and suprasellar lesion measuring 12x13mm, causing obliteration of the suprasellar cistern and inferior molding the optic chiasm. Neuro-ophthalmological assessment confirmed persistence of bitemporal hemianopsia. Four years after surgery, the lesion remains stable, and the patient reports no new symptoms.
Conclusions
GCTs are extremely rare, with just over 100 cases reported in the literature. Consistent with previous reports, this case was associated with hypopituitarism, and surgical excision was challenged by the tumor's vascularized adherent nature and proximity to critical structures. Despite partial resection, the residual lesion remained stable over four years, highlighting the indolent behavior of these tumors. This report adds valuable insights to the limited knowledge of GCTs and underscores the importance of further studies to guide future clinical practice.

Outcomes and challenges in the treatment of prolactinomas in young adults: a retrospective study of clinical and genetic factors

Bogdan Radu Ditescu[1], Andra Caragheorgheopol[2], Elena Emanuela Braha[3] & Cătălina Poiană[1,4]
[1]C. I. Parhon National Institute of Endocrinology, Department of Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]C. I. Parhon National Institute of Endocrinology, Research Laboratory, Bucharest, Romania; [3]C. I. Parhon National Institute of Endocrinology, Department of Genetics, Bucharest, Romania; [4]Carol Davila University of Medicine and Pharmacy, Department of Endocrinology, Bucharest, Romania

Introduction
Prolactinomas are the most common secretory tumors of the pituitary gland, although their prevalence in individuals under 35 years old is relatively rare. The onset of prolactinomas at a young age, particularly in male patients, may be associated with more aggressive tumor behavior. The objective of this study was to evaluate the clinical characteristics of prolactinomas and assess their response to treatment.
Methods
We retrospectively analyzed all patients under 35 years old diagnosed with prolactinoma from January 2015 to May 2024 and extracted clinical, imaging and biochemical parameters. All patients received DA (dopamine agonist) therapy as the first line of treatment. DA resistance is defined as persistent hyperprolactinemia despite high-dose cabergoline treatment.
Results
The study included 63 patients diagnosed with prolactinoma, with a mean age of 25.54 ±5.89 years at diagnosis; 57.1% were female patients. Among all, 25 patients had microprolactinomas, and 38 had macroprolactinomas. Males had a higher prevalence of macroprolactinomas (68.4%) compared to microprolactinomas (12%). All 9 patients diagnosed with giant prolactinomas, with tumor sizes exceeding 40 mm, were male. Of the patients with microprolactinomas, 12% (all female) exhibited resistance to DA therapy and required doses higher than 2.0 mg of cabergoline per week. In contrast, 55% of patients with macroprolactinomas (84.6% of whom were male) required dose escalation. Additional therapeutic approaches, such as transsphenoidal surgery combined with cabergoline (3 cases), radiotherapy (2 cases), and chemotherapy (Temozolomide) (1 case), were implemented for DA-resistant macroprolactinomas. In two cases, multimodal treatment strategies involving surgery, cabergoline, and/or chemotherapy and radiotherapy were necessary. Genetic testing for mutations in the AIP and MEN1 genes was conducted in 7 patients with high clinical suspicion (e.g., age at diagnosis < 20 years, giant

and/or invasive tumor, symptomatic hypercalcemia, and/or adrenocortical tumors). One patient was diagnosed with MEN1 syndrome through genetic testing.
Conclusions
Dopamine agonist treatment as first-line therapy, particularly for macroprolactinomas in young male patients, had limited efficacy in controlling the disease, resulting in a greater need for dose adjustments and additional treatment strategies. Genetic testing, particularly for AIP and MEN1 mutations, is recommended for young patients diagnosed with aggressive prolactinomas, but it should be reserved for those with a high clinical suspicion of underlying genetic syndromes.

Pituitary adenomas and differentiated thyroid cancer. keys to good management: a case series

Ioana Maria Posea[1], Bratu Gratiela[1], Andrei Goldstein[1], Simona Georgeta Jercalau[1], Monica Livia Gheorghiu[1,2] & Corin Badiu[1,2]
[1]"C.I. Parhon" National Institute of Endocrinology, Endocrinology 4, Bucharest, Romania; [2]"C Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Association between pituitary adenomas (PA) and differentiated thyroid cancer (DTC) requires an individualized approach. On one hand, pituitary neurosurgery and radiotherapy, as well as some drugs might impact the TSH secretion due to post-procedural hypopituitarism. On the other hand, classic treatment of DTC includes total thyroidectomy (TT), radioactive iodine therapy, and follow-up monitoring using stimulated thyroglobulin (sTgl). Herewith we describe four cases of patients with DTC and associated thyrotropic insufficiency due to simultaneous PA, underlying the importance of recombinant human TSH (rhTSH) stimulation for optimal management.

- A 45-year old acromegalic male is presenting with papillary thyroid carcinoma (PTC), who underwent a TT, and an associated thyrotropic insufficiency on account of a GH-secreting pituitary adenoma treated with transsphenoidal surgery (TSS) and additional SMSa. In the need of a RAIU for the PTC follow-up, his replacement therapy was withdraw 4 weeks, but the TSH remained low (12.85 mUI/L), under the optimal value required (>30mU/L). After rhTSH raised TSH to 72.66 mUI/l,allowed RAIU and stimulated Tgl< 0.2 ng/ml, certifying the cure of DTC.
- A 56-year old female presented with PTC and a history of macroprolactinoma irradiated twice (1985) and then treated with dopaminergic agonists, which resulted in panhypopituitarism. After performing TT for PTC, followed by one month LT4 withdraw in order to do radioiodine ablation, her TSH was only 3.94 mUI/L. After rhTSH injection, her TSH increased to 85.36 mUI/lallowing I^{131} treatment and sTgl=3.47 ng/ml.
- A 63-year old male with history of macroprolactinoma with pituitary apoplexy, treated with TSS and subsequent gonadotrophic and thyrotropic insufficiency, underwent TT for PTC. Four weeks off-treatment, TSH=13.44 mUI/L. After rhTSH, TSH=49.1 mU/l,RAIU excluded any remnant thyroid tissue and Tgl = 0.2 ng/ml, certifying the cure of DTC.
- A 65-year old female with a non-functioning pituitary adenoma and simultaneous PTC, underwent firstly TT (03.2023) and 4 months later the TSS for PA resulting in a thyrotropic deficiency. This time she underwent I^{131} therapy (10.2023) with an off-treatment (TSH=1.72 mU/l,fT4=0.3 ng/ml), without rhTSH, with a very low efficiency resulting in the need of a second radioactive iodine treatment.

Conclusion
TSH deficiency in hypopituitarism associated with DTC makes the radioactive iodine treatment or the RAIU/Tgl for the management of thyroid cancer less effective, unless rhTSH is used.

JOINT2476

Resistant prolactinomas: a retrospective insights into clinical, imaging, and demographic characteristics in the largest patient cohort

Aurika Asanova[1], Alexandra Shutova[1], Ludmila Astafyeva[2], Ekaterina Pigarova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Burdenko National Medical Research Center for Neurosurgery, Moscow, Russian Federation

Objective
To assess the characteristics of patients with resistant prolactinomas and adjuvant treatment modalities in practice.
Materials and methods
A total of 33 patients (20 men, 13 women) with resistant prolactinomas were studied, focusing on age at diagnosis, prolactin (PRL) levels and adenoma size and characteristics.
Results
The median age at diagnosis was 30 years for men and 25 years for women, with no significant difference ($\rho = 0.543$). Men had significantly higher PRL levels (median: 12,375 mU/l)compared to women (median: 2,175 mU/L), $P < 0.001$. Microadenomas were more frequent in women (38% vs 10% in men, $P = 0.051$), while macroadenomas were more common in men (85% vs 54%, $P = 0.05$). A significant positive correlation was found between the initial PRL level and the three adenoma dimensions: vertical ($\rho=0.616$, $P < 0.001$), horizontal ($\rho = 0.581$, $P = 0.002$) and anteroposterior ($\rho = 0.761$, $P < 0.001$), with correlation strength increasing from the first to the third size. In patients with microadenomas, the median PRL level was 1,500 mU/l,eight times lower than in macroadenomas (median: 12,000 mU/l,$P < 0.05$). Tumor growth was intracellar in 75.8%, suprasellar in 60.6%, parasellar in 45.5%, and infrasellar in 30.3%. Hypogonadism was found in 15 men and 10 women, with no significant gender differences ($P > 0.05$). Adrenal insufficiency (2/17) and secondary hypothyroidism (1/11) were rare, with no growth hormone deficiency. Cabergoline therapy significantly decreased PRL levels in the overall patient sample ($P = 0.003$) and in men ($P < 0.001$), but had no significant effect in women ($P = 0.866$). It notably reduced the vertical size of adenomas ($P = 0.011$), but had no effect on horizontal or anteroposterior sizes ($P = 0.410$ and $P = 0.779$). Adjuvant therapy was used in 10 patients, including tamoxifen (4), tamoxifen with bromocriptine (2), tamoxifen with cabergoline (3), and temozolomide with cabergoline (1).
Conclusions
Resistance to dopamine agonists is more common in younger patients, with men having higher PRL levels due to macroadenomas. PRL levels strongly correlate with the anteroposterior size of the adenoma. Cabergoline significantly lowers PRL levels in men, with no significant changes in women, possibly due to lower baseline levels or gender-related treatment differences. It reduces the vertical adenoma size without affecting the horizontal or anteroposterior dimensions, suggesting selective action on tumor volume. Adjuvant treatment options in real clinical practice remain highly limited. Further research into resistance mechanisms and personalized treatment is needed.

The assessment of relationship between acromegaly and hedonic hunger

Tuba Ates Kacmaz[1], Gokcen Unal Kocabas[1], Aysel Mammadyarzada[1], Ezgi Ulas[1], Mehmet Yigit[1], Melih Bektas[1], Su Ozgur[1] & Banu Sarer Yurekli[1]
[1]Ege University, Izmir, Türkiye

Objective
The aim is to evaluate the hedonic hunger and its effects on eating behaviors in patients with acromegaly characterized by excess growth hormone, compared to individuals with non-functional pituitary adenoma and those without pituitary disease.
Materials and Methods
The study included 55 patients with acromegaly, 39 patients with non-functional pituitary adenoma, and 34 healthy volunteers followed at the Endocrinology and Metabolism Diseases Pituitary Clinic of Ege University Medical Faculty Hospital. Sociodemographic characteristics, chronic diseases, fasting plasma glucose, and HbA1c values were obtained from participants. Body Mass Index (BMI) was calculated by dividing the weight in kilograms by the square of the height in meters. The Hedonic Hunger Scale (HHS) was used, and eating behaviors were assessed through face-to-face interviews using the Dutch Eating Behavior Questionnaire and the Three-Factor Eating Questionnaire. The Hospital Anxiety and Depression Scale was also applied through face-to-face interviews to identify potential psychiatric conditions.
Results
Median age of acromegaly and non-functional pituitray adennoma patients was 53 and 54 years old, respectively. Control group was age matched as 53 years old. Twenty out of 53 acromegaly patients were active according to IGF-1 levels. The rest of them were in remission. The average total score of the Hedonic Hunger Scale was found to be significantly higher in the control group compared to the acromegaly group ($P <0.05$). In the Dutch Eating Behavior Questionnaire, the average total score and median values of emotional eating and external eating were significantly higher in the control group compared to the acromegaly group ($P <0.05$). In the Hospital Anxiety and Depression Questionnaire, the depression subscale was found to be higher in the acromegaly group compared to the non-

functional adenoma group, and this difference was statistically significant ($P < 0.05$).
Conclusion
Eating behavior is regulated by a complex structure governed by homeostatic and hedonic systems, influenced by numerous central and peripheral signals. To the best of our knowledge, this is the first study assessing hedonic hunger in acromegaly. The status of education, income and the relatioship between growth hormone and ghrelin may affect hedonic hunger. It should be needed to evaluate treatment naive and post treatment acromegaly patients to explain the effect of growth hormone on hedonic hunger.

JOINT2607
The challenges of managing AVP deficiency in pregnancy with hyperemesis gravidarum
Furhana Hussein[1], Ahmed Al-ghrairi[1], Dalya Sadulah[1], Lina Eltayieb[1], Chineze Otigbah[1], Bashir Mahamud[1] & Gideon Mlawa[1]
[1]Barking, Havering, and Redbridge University Hospitals NHS Trust, Romford, United Kingdom, London, United Kingdom

Introduction
Managing AVP deficiency in pregnancy can be challenging due to the physiological changes associated with pregnancy. These changes can impact both the mother and the unborn baby. Vasopressinase, an enzyme released by the placenta, acts as a degrader of vasopressin. In a healthy female, this enzyme has an insignificant effect. However, in women with incomplete AVP deficiency, the presence of vasopressinase can exacerbate the condition during pregnancy, leading to worsening polyuria and polydipsia. These women may require higher doses of Desmopressin to manage their symptoms effectively.
Case Presentation
A 35-year-old lady presented with headaches and hyperemesis gravidarum in the antenatal clinic and maternity triage unit. Her past medical history included a diagnosis of AVP deficiency following a previous miscarriage at 16 weeks. During subsequent pregnancy, she developed frank AVP deficiency. She had polyuria and polydipsia (drinking up to 20 litres per day). The neurology team assessed and reviewed her. She had an MRI pituitary with normal findings. She was treated for gestational diabetes with metformin and she was on desmopressin for her established AVP deficiency. Blood tests since January 2017 showed sodium level ranging between 133 – 144 mmol/lwith noticeably a decline in sodium level to 130 mmol/lin January 2024. Serum osmolality was found to be within the range of 275-295 mmol/kg and urine osmolality was intermediate (between 500-600 mmol/kg). The desmopressin dose was adjusted accordingly with close monitoring.
Conclusion
Pregnancy is associated with increased blood volume and glomerular distraction rate. The risk of Gestation AVP deficiency in patients with already established AVP deficiency cannot be ignored, and the dehydration is significant especially if the patient developed hyperemesis gravidarum. In summary, managing AVP deficiency in pregnancy can be challenging and warrants close monitoring of fluids and electrolytes. The treatment should be individualized, and an MDT approach is necessary to ensure the desired outcome.

JOINT2258
Treatment with aromatase inhibitor in a patient with a leydig cell tumor: case report
Ana Casiello[1], Lorena Hidalgo Coronado[1], Gabriela Rampi[1] & Oscar Brunetto[1]
[1]Hospital General de Niños Pedro de Elizalde, Buenos Aires, Argentina

Introduction
Advanced bone age (BA) is frequently observed in patients with Leydig cell tumors (LCTs) due to increased testosterone secretion, leading to an adult height (AH) below the average for the normal population. Estrogen is the principal regulator of epiphyseal fusion in both males and females, accelerating growth plate closure. Aromatase inhibitors (AIs) have been used to enhance linear growth in boys with advanced BA and poor height potential. We present a patient with an LCT treated with an AI.
Case Report
An 11.5-year-old boy, previously healthy, was referred following an orchiectomy for an LCT in the left testicle. His height was 150.5 cm (0.71 SDS), with a mid-parental height of 171.75 cm (-0.2 SDS). His BA was 14 years (2.25 years advanced), with a predicted adult height (PAH) of 163 cm (-1.44 SDS). Tanner stage was 4 (G4, PH4), and right testicular volume was 15 mL. Laboratory results: LH: 3.7 IU/l,FSH: 12.4 IU/l,E2: 43 pg/ml, Testosterone: 4.24 ng/ml. Treatment with anastrozole, 1 mg/day, was initiated to optimize his final height. At the last visit, after 18 months of treatment (at 13.58 years old), his height was 162 cm (0.7 SDS), his BA was 15.5 years (2 years advanced), and his PAH was 167 cm (-0.8 SDS). Treatment was discontinued at this time.
Conclusions
Treatment with aromatase inhibitors decelerates epiphyseal fusion, prolonging the growth period and consequently improving adult height. In this case, treatment with an AI for 18 months resulted in an improvement in PAH. Long-term follow-up is required to evaluate whether the final height corresponds to the predicted height.

JOINT1694
Prostatic enucleation causing pituitary apoplexy in a patient with a pre-existing non-functional macroadenoma
Ibtissem Oueslati[1], Nezha Hafsi[1], Helena Mosbah[1], Florence Torremocha[1] & Xavier Piguel[1]
[1]University Hospital of Poitiers, Department of Endocrinology, Poitiers, France

Introduction
Pituitary apoplexy is a rare life threatening condition. It corresponds to an acute ischemic infarction or hemorrhage of the pituitary gland. Several factors may predispose to pituitary apoplexy or contribute to its onset. These factors include endocrine stimulation tests, treatment with dopamine agonists, gonadotropin-releasing hormone therapy, pregnancy, and anticoagulation. Herein, we report the case of a patient with a pre-existing non-functional macroadenoma presenting pituitary apoplexy as a complication of prostatic enucleation.
Observation
A 78-year old man was referred to the Department of Endocrinology for a pituitary apoplexy. His past medical history included type 2 diabetes, chronic renal failure, cardiac arythmia, and chronic obstructive pulmonary disease. In 2018, the patient presented with cognitive disorders. A brain magnetic resonance imaging was performed showing an invasive pituitary macroadenoma measuring 30 × 20 mm. The diagnosis of non-functional macroadenoma with corticotropin, thyrotropin, and gonadotropin deficiencies was established. The patient was treated with hydrocortisone, levothyroxine, and enanthate of testosterone with a regular follow-up. In October 2024, the patient had a laser enucleation of the prostate in the context of benign prostatic hypertrophy. Immediately after surgery, he presented with a sudden acute headaches associated with visual disorders. Brain MRI showed pituitary apoplexy with large and necrotico-hemorrhagic intrasellar mass, invading the cavernous sinus and compressing the optic chiasm. The ophthalmological examination revealed a bilateral decreased visual acuity, normal visual field, and total ophthalmoplegia. The patient was treated with high dose of corticosteroids. The outcome was marked by the disappearance of the headaches, the improvement of the visual disorders, and the onset of polyuria secondary to antidiuretic hormone deficiency.
Discussion
To the best of our knowledge, we report the first case of pituitary apoplexy as a complication of prostatic enucleation. Few cases of pituitary apoplexy during laparoscopic surgery were reported. In these cases, pneumoperitoneum results in the elevation in intra-abdominal pressure and in the decrease in venous return. This phenomenon subsequently leads to an increase in intracranial venous pressure, which elevates capillary pressure within the pituitary tumor and predisposes it to hemorrhage. Furthermore, some anesthetic agent may precipitate infarction in pituitary adenomas.

The incidence abnormal finding in MRI scans in children with a diagnosis of isolated GHD
Heungsik Kim [1]
[1]Wellkium Pediatric Endocrinology Clinic, Daegu, South Korea

Background
Patients with isolated growth hormone deficiency (GHD) will routinely have an MRI scan of the pituitary and brain to assess pituitary size and presence of any intracranial lesions. The result may change the threshold for monitoring for further hormone deficiencies. However the test may also detect unexpected or unrelated abnormalities.
Aim
To review the incidence abnormal finding in MRI scans in children with a diagnosis of isolated GHD.
Methods
The biochemistry and MRI reports of children with isolated GHD (peak growth hormone (GH) <7mg/l)born in a tertiary centre between 1997 from 2017 were reviewed. All children with multiple pituitary hormone deficiencies, septo-optic-dysplasia spectrum, and those children with known malignancies were excluded. Extra-cranial abnormalities such as sinusitis and mucosal thickening were excluded.
Results
81 children were diagnosed with isolated GHD. 71 children had MRI results available (4 pending). Of these, 38 (54%) were reported as normal and 33 (46%) abnormal. The median age of diagnosis was 5.99 years (range: 0.62 to 18.69), with a median height SDS of -3.45 (-0.33 to -8.41) at diagnosis. The median GH level was 3.25mg/l. The rate of MRI abnormalities was similar in the group above and below the median GH level. Of those with MRI abnormalities: 12 showed a small or hypoplastic pituitary gland, 2 had a microadenoma and 1 a cyst. 9 had an abnormal infundibulum and in 6 the posterior pituitary gland was not visible. A total of 15 MRI scans showed additional cranial anomalies (Chiari malformation (CM)($n = 4$), arachnoid cysts ($n = 3$), enlarged ventricles ($n = 1$), small optic nerves ($n = 1$), other ($n = 6$)). 3 of the children with pituitary hypoplasia had a CM.
Conclusions
Nearly half the children with isolated GHD had an abnormal MRI scan. The most frequent abnormality is pituitary hypoplasia, followed by infundibulum and then posterior pituitary abnormalities. One fifth had additional cranial anomalies; with 4 (5.6%) having a CM. CM in GHD is an uncommon but recognised association, and patients with this condition may need additional monitoring if given growth hormone treatment.

JOINT2877

Comparison between testosterone and gonadotropin treatment in adolescent males with hypogonadotropic hypogonadism

Jieun Yoo[1]
[1]Severance Children's Hospital, Yonsei University College of Medicine, Department of Pediatrics, Seoul, South Korea

Purpose
Hypogonadotropic hypogonadism refers to patients with damage to the hypothalamus or pituitary gland, resulting in low levels of FSH, LH, and testosterone, as well as prepubertal levels observed on the GnRH stimulation test. This study aimed to compare the efficacy of gonadotropin therapy and testosterone replacement therapy (TRT) in young males with hypogonadotropic hypogonadism (HH).
Methods
A retrospective analysis was conducted on 70 male HH patients under 18 years old, treated between November 2005 and December 2023. Patients were diagnosed based on clinical symptoms, underlying diseases, genetic confirmation, or prepubertal hormone levels on GnRH stimulation test. Clinical parameters and laboratory data were assessed every 6 months for up to 3 years.
Results
The etiology was congenital in 25.7% (mainly Kallmann syndrome) and acquired in 74.3% (primarily brain tumors). Of the 70 patients, 56 received gonadotropin therapy and 14 received TRT. No statistically significant differences were found between the two treatment groups in testosterone levels, growth parameters, or laboratory data. Both treatments significantly increased testicular volume and stretched penile length, but the difference between treatments was not statistically significant. Sperm analysis revealed that sperm was detected in 17 individuals (70.8%) in the gonadotropin treatment group and in 2 individuals (66.6%) in the testosterone treatment group.
Conclusions
Both gonadotropin and testosterone replacement therapies were effective in inducing puberty in adolescent males with HH. The study suggests that treatment choice should be individualized based on patient characteristics and regularly monitored for efficacy.

Clinical case of central pontine and extrapontine myelinolysis development due to severe hyponatremia

Hava Fargieva[1], Laura Ebanoidze[1], Mariia Berlovich[1], Ekaterina Pigarova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Osmotic demyelination syndrome (ODS) is a critical condition resulting from water-electrolyte disturbances, most commonly due to the rapid correction of hyponatremia. ODS comprises two forms: central pontine myelinolysis (CPM) and extrapontine myelinolysis (EPM), characterized by demyelination in the pons and the white matter of the cerebral hemispheres, respectively. Clinical manifestations range from mild tremors and dysarthria to severe complications such as dysphagia, altered consciousness, and respiratory failure requiring resuscitation.
Clinical Case
In 2018, an 18-year-old female was diagnosed with panhypopituitarism following the removal of a stalk craniopharyngioma. She was started on hormone replacement therapy, achieving medical compensation for central diabetes insipidus, secondary hypocortisolism, hypothyroidism, and hypogonadism. In December 2020, while on 0.1 mg of desmopressin twice daily, she developed dyspeptic symptoms (vomiting and diarrhea), leading to a sodium level drop to 105 mmol/l(reference range: 136–145). She was urgently hospitalized in a coma and admitted to the intensive care unit, where rapid correction of chronic severe hyponatremia resulted in complications, including CPM, EPM, bilateral supranuclear paresis of the facial, masticatory, bulbar muscles, and tetraplegia. Due to declining vital functions, a tracheostomy and gastrostomy were performed, both of which were later removed following the restoration of consciousness. MRI findings were consistent with osmotic demyelination syndrome, showing pathological signals from the basal ganglia and brainstem. During her hospitalization at the Endocrinology Research Centre in 2022, she was diagnosed with severe depressive disorder, characterized by asthenic symptoms and impaired speech expressiveness, for which neuroleptics were prescribed. A follow-up MRI in 2023 showed improvement, with a reduction in the myelinolysis focus. Notably, there were no signs of central diabetes insipidus despite the absence of vasopressin analog therapy, with a sodium level of 142.3 mmol/l(136–145) and a urine specific gravity range of 1008–1020 g/L. Currently, the patient is undergoing psychosocial rehabilitation, showing partial recovery of mnemonic and speech functions.
Results
This case highlights the severe consequences of rapid hyponatremia correction, leading to life-threatening complications such as CPM and EPM. It also underscores the broad spectrum of neurological deficits associated with ODS, which can mimic acute cerebrovascular events.
Conclusions
Increasing awareness among physicians across specialties is crucial to preventing ODS through cautious correction of hyponatremia. Furthermore, vigilant monitoring and a comprehensive multidisciplinary neurorehabilitation approach can improve survival outcomes and reduce long-term disability in patients recovering from severe hyponatremia.

Rare association of lentigo and normosmic congenital isolated hypogonadotropic hypogonadism, diagnosed in mini-puberty: clinical case report

Kristina Kokoreva[1,2], Zinaida Zyuzikova[1], Elena Pisareva[1] & Nataliya Volevodz[1,2]
[1]National Medical Research Center for Endocrinology, Moscow, Russian Federation; [2]Moscow Regional Clinical Research Institute named after M.F. Vladimirsky (MONIKI), Moscow, Russian Federation

Background
Congenital isolated hypogonadotropic hypogonadism (CIHH) is a disorder characterized by an impaired function gonadotropin-releasing hormone (GnRH). CIHH is associated with defects in 60 genes. CIHH prevalence varies from 1:4,000 to 1:10,000 newborns. "Red flags" include micropenis, cryptorchidism, deafness, anosmia, renal, skeletal, cardiac malformations, cleft lip and palate and etc.
Case report
The boy was born by a spontaneous delivery at 40 weeks of gestation. It was his mother's first pregnancy which was complicated by chronic hypoxia. Neonatal weight was 3000 g. Neonatal length was 51 cm. His Apgar score were 8 and 9.

Marriage was no closely related. At birth the patient was diagnosed with micropenis. The boy firstly was admitted at the age of 7 months complaining of micropenis. His length was 68.2 cm (-0.5 SDS), weight was 7.6 kg (-0.65 SDS). Psychomotor development was normal. Basal LH, FSH, testosterone were low. Triptorelin stimulated LH was 1.3 IU/l. hCG treatment (250 IU twice a week) was prescribed to increase penile length. At his second evaluation at the age of 13.7 years his height was 147.6 cm (-1.8 SD), his weight was 37.7 kg (-0.8 SD). The boy had severe scoliosis and multiple lentigines - dark brown and black skin spots up to 3 cm on the face, torso and hands. He was able to distinguish smells. His corpora cavernosa were 4 cm. The testicles were in the scrotum. The volume of the right testicle was 0.4 ml, the left one was 0.3 ml by ultrasound. Basal LH was 0.2 IU/l. Basal FSH was 0.7 IU/l. Total testosterone was 0.6 nmol/l. Patient had no multiple pituitary hormone deficiency.
Results
Triptorelin stimulated LH was 1.6 IU/l. CIHH was confirmed. Genetic tests revealed heterozygous previously reported pathogenic missense variant c.1016A>G: p.Tyr339Cys in 8 exon of gene *FGFR1* (NM 023110.3, HG38, chr8: 38421862T>C, rs2150755221) associated with CIHH. Injections of testosterone 75 mg im/month were prescribed to initiate puberty.
Conclusion
This clinical case demonstrates extremely rare association of lentigo and normosmic congenital isolated hypogonadotropic hypogonadism. It's the first Russian patient diagnosed with CIHH and lentigo. Due to micropenis the disease was diagnosed during mini-puberty via triptorelin test. Early diagnosis helped to effectively lengthen penis via hCG treatment at the first years of life. and to provide supportive counseling to family.

Advanced malignant insulinoma: when everything else fails, treatment with 177Lu-DOTATATE comes to the rescue

Ismene Bilbao Garay[1], Maite Perez de Ciriza[2], Sara Larrabeiti[2], Nerea Egaña[2], Joana Cillero[3], Beatriz Sanchez[4], Aitiziber Gil Negrete[3] & Estela Elias[5]
[1]Hospital Universitario Donostia, Endocrinologia y Nutricion, San Sebastian, Spain; [2]Hospital Universitario Donostia, Servicio de Endocrinologia y Nutricion, San Sebastian, Spain; [3]Hospital Universitario Donostia, servicio de Medicina Nuclear, San Sebastian, Spain; [4]Hospital Universitario Donostia, Servicio de Oncologia Medica, San Sebastian, Spain; [5]Hospital del Bidasoa, Irun, Spain

Malignant insulinoma is a rare pancreatic neuroendocrine tumor that accounts for up to 10% of all cases of insulinoma and it is characterized by the presence of severe hyperinsulinemic hypoglycaemic syndrome which encompasses a short life expectancy and great morbidity. Therapeutic management is challenging due to the need to control both hypoglycemic syndrome and tumor growth. Curative surgery is rarely applicable due to widespread metastases. We report a clinical case with metastatic malignant insulinoma accompanied by a life-threatening, and refractory hypoglycemia that was early and adequately controlled with 177Lu-DOTATATE treatment. A 51-year-old man was referred to endocrinology for hypoglucemic episodes that evolve to severe and repeated with neuroglycopenic symptoms. 7 months prior to the referral, he had been diagnosed with a grade G1, stage IV pancreatic (PNET) gastrinoma and started on PPIs, lanreotide 120mg every 28 days and everolimus achieving stabilization of the pancreatic and hepatic lesions after 6 months of treatment. We suspected a switch in functioning syndrome so we proceeded to initiate treatment with diazoxide after we confirmed hyperinsulinemic hypoglycaemia. Despite everolimus diazoxide, lanreotide 120mg/28 days, Dexamethasone, continuous enteral nutrition and parenteral infusion of glucose iv drip therapy, the episodes did not subsided. After a multidisciplinary discussion, in which other treatment options as Pasiretiode were discussed, first dose of lutetium (Lu-177)-DOTA-Tyr3-octreotate (177Lu-DOTATATE) was administered. After 7 days, the number and severity of the hypoglucemic episodes decreased, and the need for glucose iv drip, enteral nutrition and Dexamethasone, and diazoxide progressively lessen and after the second dose the episodes subsided without the need of any additional treatment. In total he was treated with 4 doses of 177Lu-DOTATATE. Eleven months after the first dose of 177Lu-DOTATATE the patient continued without hypoglycemia and with normal serum proinsulin and insulin concentrations. A somatostain receptors scan with TC 99 after the fourth dose showed radiological stability of the lesions. The patient regained the sense of well-being and transitioned to working full-time. In our experience, the use of 177Lu-DOTATATE in the symptomatic disease it should be considered, to obtain a fast control of the functionality of the disease, improving the quality of life and apparent tumor growth stabilization.

Abnormal uterine bleeding due to von willebrand disease (experience of a specialized pediatric endocrinology consultation)

Nihad Selim[1], Yahia Chebini[1], Hasna Sehab[1], Ahmed Boustil[1] & Nadira Bouchair[1]
[1]Saint Therese Clinic, University Hospital of Annaba, Pediatrics, Annaba, Algeria

Introduction
Abnormal Uterine Bleeding (AUB) is a frequent cause of visits to the emergency department and a major reason for concern among adolescents and their families. The most common cause of AUB, in otherwise healthy adolescents, is anovulatory cycles, owing to immature hypothalamic-pituitary-ovarian axis, although 5–36% of adolescents who present with heavy menstrual bleeding, have an underlying bleeding disorder (BD). The most common form of BDs is von Willebrand Disease, reflecting 13% of adolescents with AUB. Von Willebrand disease affects 1% of the general population, it is a hereditary hemorrhagic disease with autosomal dominant transmission (except type 3). The clinical signs vary depending on the severity of the form, it can be (mucocutaneous hemorrhage, bruising, epistaxis, gingival bleeding, AUB, etc.), type 3 is only affected by hematomas and hemarthroses. The diagnosis is made based on the dosage of the circulating vWF/F VIII complex.
Materials and Methods
In our specialized pediatric endocrinology consultation we collected 5 patients whose reason for consultation was AUB during their menarche and which recurred during subsequent cycles. We analyzed the biological and progressive clinical characteristics of the patients.
Results
The age of our patients was between 12 and 13 and a half years old. In the antecedents we identify the notion of benign epistaxis, small bleedings during dental extractions, 2 patients whose mothers had presented a delivery hemorrhage, notions of epistaxis in siblings, one patient had no pathological history. The exploration shows a normal primary hemostasis assessment, the diagnosis was confirmed by the measurement of the vWF/F Vlll complex. We hospitalized 3 of the 5 patients for blood transfusions; only one required an infusion of Von Willebrand factor (vWF), symptomatic treatment with a hemostatic aim was also used (anti-fibrinolytic type Tranexamic acid), as well as iron treatment and estrogen-progestogen treatment for most patients.
Conclusion
Von Willebrand disease is a common etiology of hemostasis disorders which can result in AUB in young adolescents; establishing a diagnosis as well as the management of these adolescents must involve an entire multidisciplinary team (pediatrician, hematologist and gynecologist, the etiological treatment (vWF) is to be discussed depending on the severity of the form and it is only systematic in severe forms, particularly type 3.

[1]Hospital de Pediatria J. *P* =Garrahan, Endocrinology, Ciudad Autonoma de Buenos Aires, Argentina

Introduction
Positron Emission Tomography (PET-CT) is commonly used for staging primary tumors. Incidental uptake in the pituitary region on PET-CT is a rare finding. The differential diagnosis includes metastasis from the primary tumor, pituitary adenoma, hypophysitis, Langerhans cell histiocytosis, or physiological uptake. While metastasis and pituitary adenomas often differ in clinical presentation and imaging characteristics, both can present with hyperprolactinemia.
Case Report
A 15.5-year-old male patient was referred to the endocrinology service after an incidental finding of increased metabolic activity in the pituitary region on PET-CT. The patient had an initial diagnosis of left proximal humerus osteosarcoma with multiple metastases (pulmonary and bone). He was undergoing chemotherapy as per the GLATO 2006 protocol, which included cisplatin, doxorubicin, and methotrexate. As part of his staging, a FDG-F18 PET-CT scan was performed, which revealed increased metabolic activity (SUV 4.8) at the left proximal humerus, consistent with osteosarcoma (primary tumor). Additionally, the scan

showed increased metabolic activity (SUV 7.2) at the sella turcica, suggestive of involvement of the pituitary gland. Hormonal laboratory tests were ordered to assess pituitary function, and a brain MRI with gadolinium contrast was performed, focusing on the pituitary region. The laboratory results revealed hyperprolactinemia with a prolactin level of 686.4 ng/dl, while other pituitary hormones remained within normal limits. Given the potential role of metoclopramide (an antiemetic) as a contributing factor, the medication was discontinued for three weeks. However, hyperprolactinemia persisted, with a subsequent prolactin level of 724 ng/dl. MRI findings showed an enlarged pituitary gland (14 × 17 mm) with focal cystic areas, hypovascularity, and no involvement of the cavernous sinuses. The pituitary stalk was displaced to the left, maintaining its caliber, and the neurohypophysis was intact. The optic chiasm was preserved. These findings were consistent with a pituitary adenoma with cystic changes (Knosp classification 0). Notably, the patient had no clinical signs of hyperprolactinemia, and neuro-ophthalmological examination was normal. Based on these imaging and biochemical findings, the diagnosis of a macroprolactinoma was assumed. Treatment with cabergoline (0.5 mg weekly) was initiated, with good tolerance. A new laboratory test and follow-up MRI under treatment are pending.

Conclusion

To date, there is no established association between osteosarcoma and prolactinoma in the literature. Although PET-CT SUV values can assist in differentiating between physiological and pathological pituitary uptake, it is crucial to complete evaluation with hormonal testing, pituitary-focused MRI, and ophthalmological assessment for proper diagnosis, follow-up, and treatment.

Hyperprolactinaemia: clinical presentation and dopamine agonist side effects

Frederik Klit[1,2], Sara Jensen[2], Anna-Sofie Barrett[2], Christian Rosendal[2,3], Amar Nikontovic[1], Jesper Karmisholt[2,3] & Jakob Dal[2,3]

[1]Aalborg University Hospital, Steno Diabetes Center North Denmark, Gistrup, Denmark; [2]Aalborg University, Department of Clinical Medicine, Gistrup, Denmark; [3]Aalborg University Hospital, Department of Endocrinology, Aalborg, Denmark

Introduction

Pituitary diseases are diagnosed with increased frequency and with changes in the clinical presentation. Thus, we aimed to investigate the changes in clinical presentation of prolactin secreting pituitary neuroendocrine tumours (PRL-PitNET) and idiopathic hyperprolactinemia (IDH) including side effects of dopamine agonist (DA) treatment.

Methods

Patients with a PRL-PitNET or IDH were identified via ICD-coding in the period 2017-2022 in the North Denmark Region, Denmark. Data were collected from electronic patient records. Multiple imputation by chained equations were used for side effect association analyses.

Results

We identified 244 patients with a PRL-PitNET or IDH corresponding to a prevalence of 41.3 (95%CI: 39.2-43.5) per 100,000 pr year and an incidence rate of 2.8 [95%CI: 2.3-3.4] per 100,000 person years. Median age at diagnosis was 30 [IQI: 24;41] years. 77% were women. The prolactin level was 3.1 [IQI: 1.8;12.0] times upper reference limit. Median tumour diameter at diagnosis was 9 [IQI: 6;16] mm, and stabile over time. Macroadenomas constituted 46%. Women <53 years presented with menstrual disorders (90% *without hormonal contraceptives) and galactorrhoea (56%). Men presented with decreased libido (40%) and erectile dysfunction (34%), whereas galactorrhoea was uncommon (6% (n = 3)). 216 persons were or had been treated with DA. Normalisation of prolactin was achieved in 83% of patients on DA and <3% underwent surgery due to treatment resistance. However, 46% experienced concomitant side effects to DA. 19% (of 216) had specifically persistent side effects on DA and despite many attempted different DAs. 7% of all treated with DA underwent surgery or were followed without DA due to DA side effects. Side effects were not associated with age, sex, prolactin level or time to prolactin normalisation.

Conclusion

The prevalence of PRL-PitNET and IDH seem stabile. However, patients were younger and with lower prolactin levels despite a large proportion of macroadenomas. DA is effective. However, side effects were a more severe clinical problem than previously reported.

JOINT2122

Longitudinal assessment of growth velocity, IGF-I and fasting insulin in relation to pubertal timing in healthy boys

Kaspar Sørensen[1], Casper Hagen[2], Lise Aksglaede[2], Rikke Jensen[3] & Anders Juul[4]

[1]Copenhagen University Hospital, Copenhagen, Denmark; [2]Copenhagen University Hospital, Dept. of Growth and Reproduction, Copenhagen, Denmark; [3]Herlev University Hospital, Herlev, Denmark; [4]Copenhagen University Hospital, Copenhagen, Denmark

Context

Age at puberty has declined concomitant with a tendency to become taller. This paradox – becoming taller despite diminished total growth period – may rely on faster linear growth during childhood and puberty in boys, which has previously been shown for girls.

Objective

Growth velocity, skinfold thickness (SFT), IGF-I and fasting insulin levels in relation to pubertal timing; A) early: below median age for testicular volume enlargement (TV) >3 ml and B) late pubertal onset (above the median age) in healthy boys.

Design and setting

Longitudinal study with biannual assessment of TV, SFT, growth velocity, IGF-I and fasting insulin levels. Peak height velocity (PHV) was determined by a statistical model.

Participants

105 boys (947 examinations) at a median of 9.0 years at first examination. Age at pubertal onset was available in 62 boys.

Results

Early maturing boys had significantly higher growth velocity (mean δ 0.45 (0.17 – 0.72) cm/yr; $P < 0.001$) compared with late maturing boys evaluated over the peri-pubertal period (-/+ 3 years before/after pubertal onset). However, the late maturing boys were taller than the early maturing boys (mean δ 6.4 (1.0 – 11.8) cm; $P = 0.023$) 3 years after pubertal onset. IGF-I and fasting insulin levels were similar between early and late maturing boys when evaluated in relation to age at pubertal onset. Independent of puberty, the changes in IGF-I were associated with the changes in height ($P < 0.001$) evaluated over the first 2 years after pubertal onset.

Conclusion

Early maturation was associated with increased growth velocity and PHV. However, it was not sufficient to compensate for the shorter total growth period, as seen for girls. Changes in IGF-I were related to growth but were independent of pubertal timing.

Arginine vasopressin deficiency in a baby with variant of uncertain significance found in the PCSK1 gene

Suki Suk Yan Chan[1], Ka Yee Chan[1] & Kent Ho-chung Yau[1]

[1]Prince of Wales Hospital, The Chinese University of Hong Kong, Sha Tin, Hong Kong

A premature baby born at 30 weeks and 6 days with a birth weight of 0.9kilograms presented on day 20 of life with diuresis symptoms. The urine output was 4-6ml/kg/hour and associated hypernatraemia with sodium of over 150mmol/l[RR 137-144], serum osmolality 320mOsmkg [RR 275-295], urine osmolality 160mOsmkg. The diuresis was responsive to intravenous desmopressin initially (0.04micrograms/kg/dose as required). The initial working diagnosis was Arginine vasopressin deficiency. Magnetic resonance imaging pituitary performed on day 37 showed an unremarkable anterior pituitary gland and bright spot of the posterior pituitary gland not well delineated. No destructive pituitary lesion or suprasellar mass. The desmopressin was later changed to sublingual (Nocdurna 6.25micrograms daily equivalent to 4micrograms/kg/dose). At one month of life, a spot copeptin showed a level of 31.5pmol/l[RR ≥21.4 diagnostic of AVP resistance]. This became a bit of a diagnostic dilemma therefore further work up was performed. At 2 months of age a DDAVP test was performed which showed a mixed picture of Arginine vasopressin deficiency and resistance. It was noted after regular sublingual desmopressin was given up to 2-3 times a day there was still diuresis noted. Diuresis was noted with single therapy of desmopressin. A trial of hydrochlorothiazide (1mg/kg/day) and restricted renal solute load (<14mosmo/kgH2O/kg) was unsuccessful due to hypontraemia of sodium 128mmol/l[RR 137-144]. After some titration, the diuresis was well controlled with sublingual desmopressin 6.25micrograms three times a day

equivalent to 2 micrograms/kg/dose. Regarding the other pituitary axis, this baby's cord thyroid stimulating hormone was normal and on day 21, noted to have increased thyroid stimulating hormone 15.3 mIU/l[RR 0.72-11] with low free thyroxine 9.8 pmol/l[RR 11.5-28.3] and thyroxine supplement was started. There was a history of low cortisol level at 1 week life. A short synacthen test was performed on 1 month which showed a peak cortisol level of 217nmol/l[RR $\geq$380 nmol/L] ACTH $<$1.6 pmol/l[RR $<$10.2]. Hydrocortisone replacement was started at 10mg/m^2/day. A whole exome sequence result at 2 months of age showed 2 compound heterozygous variant of uncertain significance in PCSK1 gene. Maternal variant inherited showed Heterozygous NM_000439.5(PCSK1):c.844C$>$T p.(Arg282Trp). Paternal variant inherited showed Heterozygous NM_000439.5(PCSK1):c.493G$>$A p.(Val165Ile). This baby did not show other phenotypic features of the PCSK1 gene including neonatal diarrhoea and proinsulin was normal. We will need to observe further for possibility of future obesity and hypogonadotrophic hypogonadism.

A case of multiple neuroendocrine tumors in MEN1: cushing's disease, prolactinoma, and multiple pancreatic NETS including insulinoma

Beatriz Tavares da Silva[1], Diogo Neves[1], Maria Teresa Pereira[1], Carolina Noronha[1], Elsa Castro Silva[1] & Cláudia Amaral[1]
[1]Unidade Local de Saúde de Santo António, Porto, Portugal

Introduction
Multiple Endocrine Neoplasia type 1 (MEN-1) is a rare hereditary syndrome characterized by the development of multiple NETs that significantly disrupt endocrine function. Both Cushing's Disease (CD) and prolactinoma is uncommon, with less than 1% presenting with multiple pituitary neuroendocrine tumors (PitNET). Similarly, insulinoma represents an infrequent finding in MEN1. This case highlights the intricate diagnostic and therapeutic challenges posed by MEN1.
Case Presentation
A 28-year-old male presented with rapid weight gain and abdominal striae. Physical examination showed cushingoid and hypogonadal facies, acanthosis nigricans, BMI 40.4 kg/m^2, BP 142/73 mmHg, and violaceous striae. Elevated nighttime salivary cortisol 0.478 µg/dl (0-0.208) and 24-hour urinary free cortisol 187.0 µg/24h (4.3-176.0) confirmed hypercortisolism. Elevated ACTH 40.8 pg/ml (1.5-12.4), a 7 mm PitNET at MRI, and petrosal sinus sampling confirmed CD diagnosis. Complete laboratory tests: prolactin 65.6 ng/ml (4.04-15.2), testosterone 0.80 ng/ml (2.8-8.0), PTH 229.0 pg/ml (15-65), hypercalcemia 3.16 mmol/l(2.15-2.50). Abdominal imaging identified 6 pancreatic lesions consistent with pNETs (major at head: 21x14mm). DEXA Z score: femoral neck-1.5, distal wrist -1.8. Genetic testing for MEN-1: positive (c.825-1G$>$A mutation). Hypercalcemia was temporarily controlled with zoledronic acid, deferring parathyroidectomy. Initial management focused on CD treatment due to detected complications: hypogonadotropic hypogonadism, secondary hypothyroidism, class 3 obesity, hypertension, osteopenia. Post-transsphenoidal surgery, morning plasma cortisol was 18.5 µg/dl; histopathology revealed only a prolactin-secreting PitNET. During hospitalization, additional functional studies of pNETs were performed, confirming endogenous hyperinsulinemia (glucose: 47 mg/dl, C-peptide: 7.28 ng/ml, insulin: 33.0 µU/ml), with normal levels of VIP, gastrin, somatostatin, and glucagon. 68-Ga-NOTA-PET revealed multiple pNETs, with biospy guided by ecoendoscopy identifying a well-differentiated G1 pNET. Due to persistent CD and confirmed insulinoma without localization, cabergoline, lanreotide, and continuous glucose monitoring were initiated. Metyrapone started 1 month after improved cortisol levels (24-hour urinary free cortisol: 61.6 µg/24h) , with documented symptomatic hypoglycemia post-metyrapone despite prior initiation of lanreotide. The patient is awaiting a 68-Ga-NOTA-exendin-4 PET scan in Switzerland to localize the insulinoma and guide for possible minimal invasive treatment options, along with the potential consideration of reoperation for CD and parathyroidectomy.
Discussion
This case underscores the complexity of managing MEN1 in a young patient with CD, prolactinoma, primary hyperparathyroidism, and multiple pNETs, including an insulinoma. Management of MEN1 requires careful prioritization, as not all conditions can be addressed simultaneously. Localizing the insulinoma is crucial to minimize the risks associated with invasive pancreatic surgery, while timely treatment of CD is essential due to its associated complications.

The role of IGF-1 in monitoring prolactinoma patients: paradox or additional diagnosis?

Patricia-Maria Anton[1], Nicoleta Baculescu[1,2], Iulia Florentina Burcea[1,2], Ramona Dobre[1,2], Roxana Dusceac[1,2], Găloiu Simona Andreea[1,2], Dan Alexandru Niculescu[1,2], Serban Radian[1,2], Raluca Trifanescu[1,2], Cristina Capatina[1,2] & Catalina Poiana[1,2]
[1]"CI Parhon" National Institute of Endocrinology, Pituitaru Disorders, Bucharest, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction
Pituitary adenomas secreting prolactin primarily consist of lactotroph cells; however, co-secretion of growth hormone (GH) may also occur at diagnosis or during follow-up. Levels of IGF-1 may paradoxically increase during Dopamine Agonist (DA) treatment.
Objective
To assess IGF-1 levels in patients with prolactinoma at baseline and during DA treatment and determine the frequency of silent acromegaly diagnosed during follow-up.
Methods
We retrospectively analysed 53 patients with prolactinoma who were followed up in our department, with IGF-1 levels measured at baseline and during DA treatment without intervening surgery. The median follow-up was 32.1 months (IQR: 14.9-68).
Results
67.9% of cases were male, and the median age was 40 years (IQR: 32–56). Median baseline IGF-1 level was 174.2 ng/ml (IQR: 118.5–200.2), with 9.4% exceeding the upper limit of normal (ULN) (1-1.15 $\times$ ULN). The median prolactin level was 707 ng/ml (IQR: 164.5–3404.8). Macroadenomas were identified in 79.3% of cases, with a median tumour diameter of 20 mm (IQR: 10.6–35 mm). During DA treatment, the median IGF-1 level increased significantly to 211.6 ng/ml (IQR: 153.5–260.4, $P = 0.001$). The proportion exceeding ULN rose from 9.4% to 22.6% ($P = 0.07$) (1-2.13 $\times$ ULN). During follow-up, only one patient was diagnosed with silent acromegaly 22 months after the diagnosis of prolactinoma (1.89%). Among those exceeding the ULN (12 cases), eight underwent OGTT with normal GH suppression (mostly during DA treatment). Of the others, one was lost to follow-up, and three experienced IGF-1 normalisation after 2-2.5 years. IGF-1 peaked within the first two years, followed by a significant decline after 24 months ($P = 0.001$), suggesting transient elevations.
Conclusion
IGF-1 increased significantly during DA treatment, with most elevations occurring in the first two years, followed by a decreasing trend. Silent acromegaly was rare (1.89%). When IGF-1 exceeds ULN, GH assessment during OGTT and IGF-1 reassessment after DA discontinuation are advised. Periodic IGF-1 monitoring should be considered for patients with prolactinoma.

Outcome of two closely spaced postcesarean pregnancies in a patient with prolactinoma: a case report

Yasmin El-Taravi[1], Svetlana Vorotnikova[1], Ketevan Akhvlediani[2] & Fatima Burumkulova[2]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Moscow Regional Research Institute of Obstetrics and Gynecology, Moscow, Russian Federation

Background
Prolactin-secreting adenomas necessitate careful prenatal management due to their potential for growth during pregnancy. This report presents a challenging case of a 28-year-old woman with a prolactinoma who experienced two closely spaced pregnancies, both of which resulted in cesarean deliveries.
Case Report
A 28-year-old woman first presented to our hospital at the age of 26 years, at 35-36 weeks of gestation, with a 5-year history of a prolactin-secreting adenoma. A pituitary MRI scan in 2018 revealed a microadenoma (6 $\times$ 4 mm), which was associated with headaches, elevated prolactin levels, and oligomenorrhea. From 2019, she was initially treated with cabergoline, which resulted in a reduction of prolactin levels (21 ng/ml), tumor regression, and the resumption of normal menstruation. In 2021, conflicting prolactin levels and MRI results were obtained. In March 2021, tumor growth (1.1 $\times$ 0.5 $\times$ 0.8 mm) and an increased prolactin

level (52.5 ng/ml) were observed. However, subsequent testing showed that her prolactin level decreased to 21.7 ng/ml. In September 2023, during her first pregnancy at 35-36 weeks of gestation, she presented with right-sided homonymous hemianopsia on visual field testing. Due to these findings, a cesarean delivery was recommended. A follow-up pituitary MRI scan was scheduled for 6-8 weeks postpartum. However, the patient conceived again just two months after the first cesarean delivery. With informed consent, a pituitary MRI scan without contrast was performed during the second trimester in February 2024, revealing a tumor mass of 7 × 10 mm. She subsequently delivered her second child via cesarean section at 38.5 weeks of gestation. Four weeks postpartum, a pituitary MRI scan with contrast showed tumor regression (3.5 × 3 mm).

Discussion

Pregnancy can induce high mitotic activity of lactotrophic cells in the pituitary, potentially leading to tumor growth in patients with prolactinomas. Enlarged tumor masses can compress surrounding structures, sometimes necessitating cesarean section for delivery. Pregnancy may limit the use of contrast during pituitary MRI scans; therefore, such scans might be required postpartum. Moreover, patients should be advised to wait at least 18-24 months between delivery and subsequent pregnancy to mitigate obstetric risks. Comprehensive prenatal, natal, and postnatal care is crucial for patients with prolactinomas.

JOINT2243

Assessing pubertal suppression with 3.75 mg monthly vs. 11.25 mg three-monthly leuprolide acetate in girls with central precocious puberty

Fatih Kilci[1], Emre Sarıkaya[1] & Nurhan Özcan Murat[1]
[1]Kocaeli City Hospital, Child and Adolescent Psychiatry, Kocaeli, Türkiye

Introduction

Gonadotropin-releasing hormone (GnRH) analogs, such as Leuprolide acetate (LA), are the standard treatment for central precocious puberty (CPP). The 1-month formulation of LA is widely used; however, comparative data on the effectiveness of the 11.25 mg three-monthly formulation remain limited. This study aimed to evaluate the efficacy of 3.75 mg monthly and 11.25 mg three-monthly LA in achieving pubertal suppression in girls with CPP.

Methods

A total of 136 girls with CPP were included in the study. Eighty-six patients were treated with LA 3.75 mg monthly, and fifty patients received LA 11.25 mg every three months for one year. Anthropometric, laboratory, and radiological measurements were compared at the beginning and the end of the treatment period. Pubertal suppression was defined as a luteinizing hormone (LH) level below 4 IU/lat 90 minutes after GnRH analog administration.

Results

Baseline demographic and clinical characteristics did not differ between the groups. The mean age of all patients at baseline was 8.3 ± 0.7 years. The mean age was 8.4 ± 0.8 years in the 3.75 mg group and 8.2 ± 1 years in the 11.25 mg group, with no significant difference between the groups (p: 0.210). After 12 months of treatment, there were no significant differences between the two groups in terms of bone age- chronological age difference, height standard deviation score (SDS), body mass index SDS, or uterine volume. Pubertal suppression was achieved in 72.1% of patients in the 3.75 mg group and 78% in the 11.25 mg group ($P = 0.291$). Post-treatment LH levels were comparable between the two groups (3.75 mg: 2.2 ± 2 IU/l,11.25 mg: 2.3 ± 1.6 IU/l,$P = 0.894$).

Conclusions

The 11.25 mg three-month depot of LA demonstrated comparable efficacy to the 3.75 mg monthly depot in terms of pubertal suppression, and hormonal control. Both regimes showed effective suppression of puberty. However, the 11.25 mg three-month formulation may offer improved patient compliance due to the less frequent dosing schedule, making it a more convenient treatment option while maintaining similar safety and efficacy in managing CPP.

Diagnosis of cushing's disease by desmopressin stimulated bilateral inferior petrosal sinus sampling: a case report

Tamer Özsarı[1], Beray Selver Eklioğlu[1], Mehmet Emre Atabek[1] & Bekir Turgut[2]
[1]Necmettin Erbakan University Faculty of Medicine, Department of Pediatric Endocrinology, Konya, Türkiye; [2]Necmettin Erbakan University Faculty of Medicine, Department of Radiology, Konya, Türkiye

Introduction

The most common cause of ACTH-dependent Cushing's syndrome is Cushing's disease (CD) due to an ACTH-producing tumor in the pituitary gland Bilateral petrosal sinus sampling (BPSS) is the gold standard for determining the source of hypercortisolism. There is limited information about desmopressin use in the literature. In this case, BPSS protocol performed because there was a lesion that could not be clearly distinguished in imaging, despite evaluating the clinical and laboratory findings.

Case

A 12-year-old girl presented to our clinic with complaints of weight gain over the past year, absence of height increase, and hair growth on her face, back, and genital area. Her height was 145 cm (-1.0 SDS), weight was 55 kg (+1.3 SDS), and body mass index was 26.9 kg/m^2 (2.12 SDS). Physical examination revealed a moon-shaped face, plethoric appearance, abdominal striae, acanthosis nigricans in the axilla, and buffalo hump. A high basal cortisol level (29 µg/dl), ACTH level (91 pg/ml) was detected. Diurnal rhythm was disrupted. Cortisol levels were not suppressed in the dexamethasone suppression test (single dose, 1 mg, orally) (12,8 µg/dl) and the low-dose dexamethasone test (7,82 µg/dl). The decrease in cortisol levels after the low-dose dexamethasone suppression test was less than 50%. Twenty-four-hour urinary cortisol level (374 µg/day) was high. The adrenal glands appeared normal on ultrasound. No significant pathology was detected on the pituitary MRI. In intravenous desmopressin-stimulated BPSS, samples taken from the right pituitary showed significantly elevated ACTH levels (Table-1), leading to a diagnosis of Cushing's disease. Surgery was planned.

Conclusion

In cases of hypercortisolism related to ACTH where imaging results are inconclusive, a BPSS should be performed. When CRH is not available for BPSS, the use of desmopressin appears to be safe.

Table 1. Bilateral petrosal sinus sampling (BPSS) results.

	ACTH(pg/ml)						CORTI-SOL (µg/dl)

Unveiling hypothalamic syndrome, beyond obesity: diagnostic challenges and management strategies in pediatric patients - a report of 2 cases

Marianne taub [1], Juan Pablo Fernandez[2], Cecilia Okuma[2], Samuel Valenzuela[2], Osvaldo Koller[2], Gabriel Campos[2], Juan Jose Marengo[2] & María Isabel Hernandez[1,2]
[1]Institute of Maternal and Child Research. Faculty of Medicine. Universidad de Chile, Santiago, Chile; [2]Department of Neurological Science. Faculty of Medicine. Universidad de Chile. Asenjo Institute of Neurosurgery. Santiago. Chile., santiago, Chile

Introduction

Hypothalamic syndrome (HS) in childhood is rare and typically is strongly associated with severe obesity. Its incidence ranges from 0.05 to 10 per 100,000 persons per year and may result from genetic or acquired causes that damage the hypothalamic nucleus, such as suprasellar brain tumors or their treatments. Beyond severe obesity, HS may present additional manifestations, including pituitary dysfunction, sleep disturbances, temperature dysregulation, loss of thirst, and behavioral problems. These symptoms are often not promptly recognized, leading to delayed management and a deterioration in quality of life.

Objectives

Present two cases of HS to highlight the complexity of diagnosis and management. **Case 1:** A 5-year-old male was diagnosed with craniopharyngioma (CP) at age 4 and underwent gross total resection. He developed multiple pituitary hormone deficiencies (MPHD), requiring treatment with levothyroxine,

hydrocortisone, desmopressin (DDAVP), and growth hormone (GH). He experienced hyperphagia, resulting in obesity with a BMI of +4 SD in a short time. Hypodipsia necessitated supervision to meet daily water intake, and hyperthermia, with a basal temperature of 38°C that spiked to 40°C on warm days, was managed with cold baths.
Case 2: A 12-year-old male was diagnosed with CP at age 2. He underwent multiple surgeries and proton beam therapy, subsequently developing MPHD and requiring treatment with cortisol, levothyroxine, DDAVP, and GH. He also developed adipsia, resulting in recurrent hospitalizations for dehydration and hypernatremia. During his most recent admission, he was clinically dehydrated, tachycardic, and had low-normal arterial pressures. He scored 0 on the thirst scale and had a serum sodium level of 162 mEq/L. Treatment included desmopressin adjustment to 0.375 mg/day and supervised scheduled water intake. Serum sodium normalized by the third day, and he was discharged with a sodium level of 147.3 mEq/land a daily water intake of 1500–2000 mL.
Conclusion
HS is a rare and challenging condition to diagnose, requiring a high index of suspicion in cases involving hypothalamic tumors. Adipsia complicates management, making close clinical and laboratory follow-up essential to optimize outcomes. Hyperthermia is common and should be distinguished from infection-related fever to avoid unnecessary high-dose glucocorticoid treatments.

A single-center experience of the effect of triptorelin on final height in girls with precocious or early puberty

Georgia Sotiriou[1,2], Anastasios Serbis[3], Assimina Galli-Tsinopoulou[2,4] & Athanasios Christoforidis[1]
[1]First Department of Pediatrics, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Hippokratio General Hospital, Thessaloniki, Greece; [2]Program of Postgraduate Studies "Adolescent Medicine and Adolescent Health Care", School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece; [3]Department of Pediatrics, School of Medicine, University of Ioannina, 45110 Ioannina, Greece, Ioannina, Greece; [4]Second Department of Pediatrics, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, AHEPA General Hospital, Thessaloniki, Greece

Aim
To evaluate the effect of triptorelin on the final height of girls with precocious or early puberty, compared to the untreated group, and to investigate factors that contribute to the maximum effectiveness of treatment in terms of final height.
Methods
We retrospectively collected data from medical records and organized follow-up phone calls to all girls evaluated in our Pediatric Endocrinology Outpatient Clinic for precocious or early puberty during the last two decades. One hundred and seventy-eight girls (85 with precocious and 93 with early puberty), of whom 85 received treatment with triptorelin and 93 did not, were included in the final analysis. The patients' anthropometric characteristics, bone age and midparental height, as recorded at their visits, were collected. Final heights, measured and documented by health professionals, and the exact date of the first menstruation (menarche) were collected after telephone communication. Logistic regression analysis was performed to assess the effect of various parameters on the response to triptorelin treatment.
Results
The difference in mean standard deviation (ΔSDS) of final and midparental height did not show significant difference between treated and untreated girls (Δ Height SDS (Final – Midparental): -0.20 ± 0.89 vs -0.28 ± 0.83, $P = 0.243$). The results were similar when we compared the early (-0.22 ± 0.71, vs. -0.17 ± 0.83, $P = 0.778$) and precocious puberty (-0,19 ± 1,04, vs -0,39 ± 0,83, $P =$ 0,315) subgroups separately. As excepted, menarche occurred earlier in the precocious puberty group compared with the early puberty group (10.68 ± 1.22 vs 11.12 ± 0.90 years, $P = 0.005$) and in the untreated compared with the treated group (10.31 ± 0.91 vs. 11.57 ± 0.06 years, $P < 0.001$ for early puberty, and 11.53 ± 0.90 vs. 9.86 ± 0.86 years, $P < 0.001$ for precocious puberty). Predictors of final height were height at diagnosis (positively correlated), midparental height, and bone age at diagnosis (negatively correlated).
Conclusions
There was no significant difference in final height between treated and untreated girls, and triptorelin was effective in delaying the onset of menarche. Factors contributing to a better final height in the treated group were higher height at baseline, lower midparental height, and younger bone age.

The impact of turner syndrome and hypogonadism on brain and hypothalamic-pituitary structure: effects of treatment with sex steroids and growth hormone

Aml Sabt[1], Nada Alaaraj[2], Fawzia Alyafei[2], Noor Hamed[2], Shayma Ahmed[2], Ahmed Elawwa[2] & Ashraf Soliman[2]
[1]Sidra medicine, Doha, Qatar; [2]Hamad Medical Corporation, Doha, Qatar

Background
Turner Syndrome (TS) is a chromosomal disorder characterized by the partial or complete loss of one X chromosome, affecting 1 in 2,500 females. TS often leads to hypogonadism, short stature, and cognitive deficits, particularly in visuospatial, memory, and executive functioning. These manifestations correlate with structural anomalies in the brain and hypothalamic-pituitary axis. Treatments with growth hormone (GH) and sex steroids aim to mitigate these effects, yet their impact on neuroanatomy and function requires further exploration.
Objectives
To evaluate the influence of Turner Syndrome and hypogonadism on brain and hypothalamic-pituitary structure and investigate the effects of GH and sex steroid therapies on mitigating these changes.
Methods
This structured review integrates data from studies conducted between 1990 and 2024. Analyses included magnetic resonance imaging (MRI) findings, hormonal profiling, and neuropsychological assessments. Sample sizes ranged from single case studies to large cohorts. Metrics included brain volume, pituitary structure, and cognitive outcomes, stratified by treatment regimens.
Detailed Results
1. Structural Changes in TS: TS is associated with smaller parieto-occipital gray matter, reduced hippocampal volume, and alterations in basal ganglia and cerebellar regions (O'Donoghue *et al*., 2020).
2. Effects of Treatment:.
• GH therapy improves body composition, increases lean mass, and enhances metabolic profiles but has mixed effects on brain structure (Wang *et al*., 2020).
• Estrogen replacement therapy significantly improves white matter development and hypothalamic-pituitary axis normalization (Viuff *et al*., 2022).
3. Cognitive Outcomes: Working memory shows improvement with combined GH and oxandrolone therapy but no significant change with GH alone (Soliman *et al*., 2024).
Discussion
TS and hypogonadism profoundly impact neuroanatomy and the hypothalamic-pituitary axis. GH and sex steroid therapies offer substantial benefits, particularly when initiated early and tailored to individual needs. However, the risk of cardiovascular and metabolic complications necessitates careful monitoring.
Conclusion
GH and sex steroid therapies are pivotal in addressing the neurodevelopmental and hypothalamic-pituitary deficits in TS. Early and comprehensive treatment strategies significantly enhance structural and functional outcomes, underscoring the importance of individualized approaches.

Comparative models of acromegaly: a north american cohort of 4620 cats with presumed feline hypersomatotropism (acromegaly)

Rebecca Egbert[1], Stijn Niessen[2], Rob Fowkes[3] & Brian Petroff[1]
[1]Michigan State University College of Veterinary Medicine, Pathobiology & Diagnostic Investigation, Lansing, United States; [2]Royal Veterinary College, Clinical Sciences & Services, Hatfield, United Kingdom; [3]Michigan State University College of Veterinary Medicine, Small Animal Clinical Sciences, East Lansing, United States

Comparative models of spontaneous endocrinopathies are powerful tools to understand disease etiology. The study of endocrine diseases in companion animals is particularly useful, as these animals share their environment with humans, and typically display clinical signs that phenocopy human symptoms. One such disease in domestic cats, hypersomatotropism (HST, feline acromegaly), is a disorder of excessive growth hormone and increased IGF-1 (Insulin like Growth Factor 1). Feline acromegaly is usually caused by hyperplasia or neuroendocrine tumors of the pars distalis of the pituitary gland. In this retrospective study, we used serum IGF-1 results to investigate population characteristics for domestic cats with HST in the United States and Canada. Laboratory records from 1Jan06 to 31Dec22 were reviewed and animals with a circulating IGF-1 hormone concentration of 190 nmol/l(1,450 ng/ml) or greater

were presumed to have acromegaly. This review identified 4,620 such cats with a mean age (n = 4,351) of 11.2 years (median: 11.2, range: .5-20.3yr) and mean weight (n = 2,086) of 6.03 Kg (median: 5.91, range: 2.27-15.0 Kg). Males outnumbered females in the database, which included 3,048 males and 1,181 females. Domestic Short/Medium/Longhair cats were the most prevalent breed (n= 3,563; 77%), followed by Maine Coon cats (n = 120; 2.6%) and Siamese cats (n = 111, 2.4%). Just under half of the animals (n = 2,037, 44%) had a history of diabetes mellitus on the submission form. Most submissions were from the US (n = 4,347, 94%) with the largest number of affected cats being submitted from California (n = 841, 18.2%), New York (n = 604, 13.1%), Massachusetts (n = 402, 8.7%), Colorado (225, 4.9%), and Texas (200, 4.3%). The mean serum IGF-1 concentration of these animals was 358 nmol/ml (median: 345, range 190-761 nmol/ml). For comparison, an age and sex matched control group of 95 animals with residual samples previously submitted for unrelated testing was selected. The mean IGF-1 concentration for the control group was 97 nmol/ml (median: 85, range 0-311 nmol/ml). Therse data suggest that feline acromegaly is diagnosed most frequently in older male cats in North America, residing in areas that are likely to be more urbanized and subject to environmental pollutant exposure. Furthermore, some breed disposition is evident, suggesting a genetic component to the disease etiology in cats. Given that the prevalence of this disease in cats is potentially 10 times that seen in humans, we suggest that feline HST represents an excellent comparative model of acromegaly that warrants further investigation.

Concomitant development of central diabetes insipidus and cerebral salt-wasting syndrome in a child with subarachnoid hemorrhage

Irina Halvadzhiyan[1], Stanimira Elkina[1] & Chayka Petrova[1]
[1]Department of Pediatrics, Medical University of Pleven, Bulgaria, Pleven, Bulgaria

Introduction
Diabetes insipidus, syndrome of inappropriate antidiuretic hormone secretion (SIADH), and cerebral salt-wasting syndrome (CSWS) are observed in children with central nervous system (CNS) injuries (e.g., intracranial surgery in the hypothalamic-pituitary region, brain trauma, intracranial hemorrhage, neuroinfections, etc.). Central diabetes insipidus (DI) leads to elevated serum sodium levels and polyuria, whereas SIADH and CSWS are well-known causes of hyponatremia and polyuria in neurological patients. However, the simultaneous occurrence of DI and CSWS in pediatric patients is rarely described and often results in unfavorable outcomes.
Case Presentation
We present the case of a 15-year-old boy who suffered a traumatic brain injury in a car accident. He underwent surgical treatment for a subarachnoid hemorrhage, after which central diabetes insipidus initially developed. Treatment with Desmopressin was initiated. Later on, during follow-up, despite adequate replacement therapy with Desmopressin, persistent polyuria and symptomatic hyponatremia with natriuresis were observed. This led to the consideration of the concomitant presence of DI and CSWS. After initiating treatment with Fludrocortisone, diuresis and serum sodium levels normalized. The combined treatment was gradually discontinued, and the child was discharged in good health within 30 days.
Conclusion
The combination of central diabetes insipidus and cerebral salt-wasting syndrome is a rare phenomenon and represents a diagnostic challenge. Delayed diagnosis and inadequate management of such cases may result in poor neurological outcomes with a high mortality rate.

Long-term follow-up is needed in primary-like hypophysitis: a late diagnosis of Langerhans cell histiocytosis case report

Miquel Léa[1], Nicolas Sahakian[2], Testud Benoit[3], Frederic Castinetti[2] & Schleinitz Nicolas[4]
[1]Service de médecine interne et immunologie clinique, Hôpital de La Conception, Assistance Publique Hôpitaux de Marseille (AP-HM), 13, Marseille, France; [2]Aix Marseille Université, MMG, INSERM U125, Marmara Institute, Assistance Publique Hôpitaux de Marseille (AP-HM), Hôpital de la Conception, CRMR HYPO, 13, Marseille, France; [3]Aix Marseille Université, Service de radiologie, Hôpital de la Conception, Assistance Publique Hôpitaux de Marseille (AP-HM), 13, Marseille, France; [4]Aix marseille université, Service de médecine interne, Hôpital de la Timone, Assistance Publique Hôpitaux de Marseille (AP-HM), 13, marseille, France

Introduction
Hypophysitis is a rare disease that affects mainly young adults. The main symptoms are headaches, pituitary insufficiency or vasopressin deficiency (AVP-D). Hypophysitis may be primary, secondary to systemic disease (sarcoidosis, L-group histiocytosis) or iatrogenic (mainly lead by checkpoint inhibitors). While hypophysitis may be part of a systemic disease at the onset, it may also precede it by several years.
Case report
A 38-year-old woman presented with a progressive onset of polyuria-polydipsia up to 9 litres per day. Diagnosis of AVP-D was quickly done after fluid restriction test, and desmopressin therapy was initiated leading to clinical improvement. She didn't have pituitary insufficiency and didn't exhibited any other symptoms such as headache or visual impairment. Pituitary MRI revealed thickening of the pituitary stalk associated with the loss of spontaneous T1 hypersignal of the posterior pituitary without symmetrical pituitary enlargement or **extra-pituitary abnormality. A large clinical, biological and radiological workup didn't identified any clues for systemic disease. More than two years after initial presentation, the patient noticed a clinically appearance of right parietal bone mass. Radiological assessment revealed a** right frontal paramedial osseolytic osseomeningeal tissue process, presenting a great uptake in 18F-FDG PET CT. Bone biopsy highlighted a BRAF V600E positive Langerhans cell histiocytosis, leading to a Langerhans cell histiocytosis with pituitary and bone manifestation.
Discussion
This illustrate that the discovery of hypophysitis should prompt a search for systemic disease, at onset and during time, since hypophysitis may precede by several years a systemic disease. Particularly, Langerhans histiocytosis should be investigated in the presence of AVP-D, thickened stalk and absence of headache.

Dealing with pituitary invaders: a corticotroph macroadenoma case

Nada Ait Kassi[1], Nouhaila Essafir[1], Sara Hairchi[1], Habbadi Zineb[2], Fatima Toulali[1], Ghizlane Sabbar[1], Kaoutar Rifai[1], Hinde Iraqi[1] & Mohamed El Hassan Gharbi[1]
[1]Ibn Sina Hospital Mohamed V University, Rabat, Morocco; [2]Ibn Sina Hospital Mohamed V University, Endocrinology, Rabat, Morocco

Introduction
Corticotroph pituitary tumors, particularly invasive macroadenomas, are rare and therapeutically challenging due to their compressive effects and systemic complications. They represent a significant cause of endogenous hypercortisolism in Cushing's syndrome. This case discusses a complex presentation of an invasive corticotroph macroadenoma in a middle-aged woman, underlining the value of tailored multidisciplinary management to achieve biochemical and clinical control.
Case Presentation
A 46-year-old woman with a history of hypertension and type 2 diabetes was diagnosed with an invasive corticotroph macroadenoma, confirmed by histopathology after transsphenoidal surgery. Imaging revealed a sellar and suprasellar mass with bone erosion and optic chiasm compression. Post-operative complications included hypogonadism and hypothyroidism, requiring hormone replacement therapy. Medical management included ketoconazole, cabergoline, and the planned introduction of Pasireotide to address tumor control and residual hypercortisolism.
Discussion
This case highlights the aggressive nature of corticotroph macroadenomas, characterized by local invasion and systemic effects such as Cushingoid features. Surgical resection remains the first-line treatment; however, complete remission is not always achievable, necessitating adjunctive therapies. Novel pharmacological approaches expand therapeutic options, such as somatostatin analogs and ACTH secretion inhibitors. Furthermore, long-term monitoring is critical due to the potential for recurrence or progression, especially in invasive forms.
Conclusion
Invasive corticotroph macroadenomas require an integrative approach, combining surgery, medical treatment, and close follow-up. Advanced therapies, like Pasireotide, offer promising outcomes in managing persistent disease. This case

underscores the importance of individualized care in achieving optimal results for complex pituitary tumors.

JOINT2370

A rare case of pituitary adenoma co-secreting ACTH and GH

Nada El Idrissi Dafali[1], Sana Rafi[1], Sara Ijdda[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]

[1]University Centre Mohamed VI. Marrakech, Department of Endocrinology; Diabetology and Metabolic Diseases, Marrakech, Morocco

Introduction

Multi-secretory pituitary adenomas have been reported in the literature. However, tumors with dual corticosomatotropic secretion are very rare. Our observation illustrates This particular entity.

Observation

A 34-year-old patient complaining of decreased libido and right unilateral temporofrontal headaches was referred to us with suspicion of Cushing's syndrome. Clinically, there were signs of hypercortisolism (cushingoid facies, faciotruncular obesity; abdominal purple stretch marks; filling of the supraclavicular fossae; and skin fragility with bruising on the legs). There were no signs of hypersomatotropism. The hormone profile was consistent with ACTH-dependent Cushing's syndrome, with a slight hyperprolactinemia of disconnection, corticotropic and thyrotropic insufficiency, and a growth hormone level of 1.5*normal. MRI revealed a left laterosellar lesion measuring 14*22*10.5 mm. After trans-sphenoidal surgery, histological examination combined with IHC revealed a pituitary adenoma with positive immunostaining for GH and ACTH. The evolution over 1 year was marked by tumour recurrence with visual repercussions requiring recourse to surgery.

Discussion

Pituitary adenomas can express and secrete different hormones. The expression of pituitary hormones in non-neoplastic pituitary cells is regulated by various transcription factors. The most important of these are PIT1 and GATA 2. It is well known that some cases of pituitary adenoma producing growth hormone (GH) may be accompanied by hypersecretion of other anterior pituitary hormones such as prolactin (PRL) or thyroid-stimulating hormone (TSH). From an immunohistochemical point of view, other hormone-producing cells of the anterior pituitary can be detected among the GH-producing cells. However, a case of GH-secreting adenoma accompanied by ACTH secretion is extremely rare. the extreme rarity of the combination of GH and ACTH could be attributed to the suppressive effect of hypercorticism on GH secretion. Multiple hormone secretion may result either from neoplastic transformation of 2 cell lines or from differentiation of one cell into a cell secreting another hormone. Surgery is often required as a matter of urgency, somatostatin analogue treatment is indicated in these patients, and monitoring is imperative.

Conclusion

We report a new observation of a rare case of pituitary adenoma co-secreting ACTH and GH responsible for hypercorticism but without notable clinical signs of acromegaly. More meticulous endocrinological and immunohistochemical examination of cases of GH-secreting adenomas could reveal the true incidence of this combination.

Familial isolated pituitary adenomas (FIPA): screening for mutations in the aryl hydrocarbon receptor interacting protein (AIP) gene

Calin Cristiana[1,2], Iulia Florentina Burcea[1,2,3], Ramona Dobre[1,2] & Catalina Poiana[1,2]

[1]CI Parhon National Institute of Endocrinology, Bucharest, Romania, Pituitary and Neuroendocrine Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]"Carol Davila" Faculty of Medicine, Endocrinology, Pituitary and Neuroendocrine Pathology, Bucure?ti, Romania

Introduction

Familial Isolated Pituitary Adenomas (FIPA) are a rare hereditary condition, accounting for 1.9–3.8% of all Pituitary Neuroendocrine Tumors (PitNET) cases. The first identified gene underlying FIPA is AIP, which accounts for 10% to 20% of FIPA kindreds. FIPA occurs in the absence of other syndromic conditions (MEN1, Carney complex) and frequently presents at a younger age with larger and locally invasive GH-secreting adenomas that are less likely to respond to first-generation somatostatin analogues (SSA).

Results

In this study, we retrospectively analyzed 1,068 PitNET patients, who presented in our institute between 2019-2024, identifying a FIPA prevalence of 1.02%. We detected 11 families with FIPA, of which 3 were homogeneous and the remaining heterogeneous. The average number of affected members per family was 2.72 ($\pm$ 0.96). The mean age at diagnosis was 47.2 years ($\pm$ 15.72). Acromegaly was the most common PitNET type in the index cases, occurring in 10 out of 11 cases (90.9%), while one index case had a non-functioning pituitary adenoma (NFPA). Among the family members of the index cases, 7 were diagnosed with NFPA, 3 with acromegaly, and 1 with prolactinoma. Regarding the index cases, the mean diameter at diagnosis of the pituitary adenomas was 18.8 mm ($\pm$ 8.79), with 8 out of 11 adenomas being invasive, as indicated by a Knosp grading. The mean number of required transsphenoidal surgeries was 1.27 ($\pm$ 0.74). Among the index cases with GH-secreting pituitary adenomas, 6 out of 10 patients currently have active disease. Genetic screening for AIP mutations was performed in 6 out of 11 cases, yielding 4 negative results and 2 results pending.

Conclusion

In conclusion, the study highlights the low prevalence of FIPA, as well as the fact that none of the tested families had a positive result for AIP mutations. Ongoing research into novel genetic and epigenetic mechanisms of pituitary tumorigenesis, alongside the storage of DNA for future genetic testing, will enhance our understanding and management of this condition.

JOINT3356

Clinical management and therapeutic options for pancreatic insulinomas – a case series

Tiberiu Manole[1], Ionela Baciu[1,2], Anda Dumitrascu[3] & Catalina Poiana[1,2]

[1]C I Parhon National Institute of Endocrinology, Clinical Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]C I Parhon National Institute of Endocrinology, Radiology, Bucharest, Romania

Introduction

A functioning Neuroendocrine Tumour (NET) syndrome is defined by the presence of a clinical syndrome combined with biochemical evidence of inappropriately elevated hormonal levels, with positive hormonal expression in NET cells on immunohistochemical staining. [1, 2] Insulinomas are the most frequent type of functioning NETs – they are the most common cause of hypoglycaemia related to endogenous hyperinsulinism. [3].

Objectives and Methods

This paper presents, from a clinical and therapeutic point of view, a case series of 3 insulinoma patients, treated in a tertiary centre.

Results

We analysed data from 3 patients, 1 woman and 2 men (median age at diagnosis - 51.6 years old) which were referred due to clinical suspicion of insulinoma – Whipple's triad with no history of diabetes mellitus or glucose-lowering treatment. We performed the fasting test for the female – hypoglycaemia ($<$45 mg/dl) with inadequate normal insulin and C peptide levels. The other 2 patients came with spontaneous glycemia of 30-40 mg/dl with a long history of frequent crises (1 every 3-4 hours) – therefore, the clinical and biochemical diagnoses were positive. The CT exam revealed a pancreatic lesion in the tail of the pancreas in all 3 patients and also adrenal adenomas with a high lipid content – probably incidentalomas. The youngest patient, aged 40, was also diagnosed with a renal tumour of 7 cm and a pituitary microadenoma. The woman has a first-degree cousin with acromegaly, but no other positive familial or personal history suggestive of MEN1 syndrome for all 3 patients – the hormonal screening for MEN1 or other functional NETs also came back negative. The 2 older patients were referred to a general surgery clinic – one had a partial pancreatectomy (the pathology report was positive for insulinoma), with no residual disease post-surgery, but he developed secondary diabetes mellitus and is currently treated with insulin. The woman recently underwent partial pancreatectomy with no complications and complete remission, while the youngest patient was referred for a nephrectomy first, an octreotide scan to confirm the localisation and is currently treated with Diazoxid until the pancreatectomy can be performed. All 3 will be followed-up yearly and genetic testing and counselling are in progress.

Conclusions

Insulinomas are rare functioning NETs, with life-threatening symptoms, isolated or part of a syndromic disease, requiring multidisciplinary teams and expert tumour boards for correct diagnosis and management, the surgical curative

excision being the only treatment to ensure a successful outcome and improve quality of life.

A case of aggressive corticotropinoma in a patient after combined treatment

Daria Lisina[1], Mariia Berlovich[1], Ekaterina Pigarova[1], Larisa Dzeranova[1], Vilen Azizyan[1], Andrey Griroriev[1] & Liliya Urusova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Treatment of aggressive corticotropinomas is a challenge due to the frequent invasive growth of the tumor which complicates radical surgery and can increase the risk of recurrence, thus together with tumor resistance to radiotherapy leads to persistence of the disease.
Clinical case
In August 2023 a Cushing disease was diagnosed in a woman of 48 years of age and according to MRI in the cavity of the sella turcica, in the suprasellar cistern, in the left cavernous sinus (Knosp IV), in the sphenoid sinuses and in the cells of the ethmoid labyrinth on the left was determined tumor tissue measuring 28x25x39 mm. Transsphenoidal adenomectomy was performed (morphology: pituitary tumor of solid structure composed of cells with amphophilic cytoplasm, 1 pathological mitosis; immunohistochemistry: expression of synaptophysin, CAM 5.2 and ACTH, Ki-67-13.4%, no expression of somatostatin receptors subtype 5). Due to clinical manifestation of adrenal insufficiency in the postoperative period was initiated hydrocortisone therapy, which was cancelled in February 2024 due to the persistence of endogenous hypercortisolism and MRI noted tumor tissue in the right part of the adenohypophysis measuring 14.5x13x12 mm and in the left cavernous sinus measuring 17x16x33 mm. In March 2024 patient was treated by repeated transsphenoidal adenomectomy. A month later due to manifestation of neuro-ophthalmologic symptoms and the spread of tumor tissue measuring 26x31x41 mm into the orbit according to MRI, another transnasal transsphenoidal adenomectomy was performed (morphology: fibrous tissue with deformed tumor cells with hyperchromic nuclei; immunohistochemistry: ACTH expression in 100% of cells, CAM 5.2 in 80% of cells, Ki-67-10%, high reaction with VEGF and PD-L1 expression in 5% of cells, no expression of LH, FSH, prolactin and somatostatin receptors subtypes 2A and 5). In June-August 2024 the patient underwent stereotactic radiation therapy (TrueBeam, 55.8 Grey). In September 2024 was confirmed persistence of the disease and MRI described tumor tissue in the left cavernous sinus measuring 10x14x14 mm, endo-suprasellar on the right measuring 16x14x14 mm and along the upper, right and lower contours of the left optic nerve. The patient was consulted by a neurosurgeon, dynamic observation was recommended.
Conclusion
The clinical case demonstrates the problems in treatment of aggressive corticotropinomas. Anti-VEGF therapy and immune checkpoint inhibitors immunotherapy in some studies has shown effectiveness in the treatment of aggressive corticotropinomas. Thus, the expression of VEGF and PD-L1 in tumor cells detected during the immunohistochemistry in this patient may provide alternative treatment options for achieving remission.

Giant prolactin-secreting pituitary adenoma: a case report

Mouna Elleuch[1], Yassmine Abdelkafi[1], Zaineb Fourati[1], Mohamed Khairi Arous[1], Nadia Charfi[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Giant prolactinomas, defined as prolactin-secreting adenomas larger than 4 cm, are rare and often present with significant compressive symptoms due to their invasive nature. They pose major diagnostic and therapeutic challenges, particularly in male patients, where late presentation is common. This case illustrates the aggressive evolution and management difficulties associated with giant prolactinomas.
Observation
We report the case of a 31-year-old male with no prior medical history, admitted for the management of a large pituitary adenoma. His symptoms began two months before hospitalization, with progressive headaches and bilateral visual impairment leading to complete blindness. Initial brain imaging (CT and MRI) revealed an invasive sellar and suprasellar mass (50 mm), extending into the cavernous sinuses, sphenoid, ethmoid, and nasal cavities, with compression of the optic pathways. The prolactin level was 138.5 ng/ml. On clinical examination, the patient was overweight (BMI = 26.53 kg/m^2) with normal blood pressure (110/80 mmHg). Neurological assessment revealed bilateral areflexic mydriasis due to oculomotor nerve (CN III) involvement, along with bilateral optic atrophy confirmed by ophthalmologic evaluation. Visual field testing showed light perception in the right eye and complete blindness in the left. There were no motor or sensory deficits. Endocrine evaluation revealed signs of thyrotropic insufficiency (fatigue, psychomotor slowing, constipation) and corticotropic insufficiency (asthenia, anorexia). The patient was initially treated with cabergoline (0.5 mg/week for three months); however, no clinical or radiological improvement was observed. He subsequently underwent transsphenoidal endoscopic surgery, with histopathology confirming an invasive prolactin-secreting adenoma. The Ki-67 proliferation index was 2%. Despite surgical intervention, his condition worsened, with a rapid increase in tumor size (80 × 70 × 60 mm) and extensive skull base destruction noted on follow-up MRI. Biochemical evaluation confirmed corticotropic and thyrotropic insufficiencies, requiring hormonal replacement therapy. Cabergoline was continued with dose escalation up to 2 mg/week, but prolactin levels continued to rise, reaching 850.8 ng/ml at 12 months. Radiotherapy was indicated but could not be initiated due to the patient's deterioration. Unfortunately, he passed away 18 months after diagnosis.
Discussion
Giant prolactinomas in men often exhibit an aggressive course with significant resistance to dopamine agonists, particularly in invasive forms. This case highlights the challenges of managing such tumors, including the need for multimodal therapy involving high-dose dopamine agonists, surgery, and potentially radiotherapy. Delayed diagnosis contributes to poor prognosis, emphasizing the need for early detection and long-term follow-up.

Autoimmune hypophysitis induced by Anti-PDL1 therapy

Yesmine Elloumi[1], Wissal Abbes[1], Dhoha Ben Salah[1], Omaima Dimassi[1], Kouloud Boujelben[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Background
New Cancer Immunotherapies such as Immune checkpoint inhibitors enhance the immune system's ability to combat tumors. However, they can trigger various autoimmune manifestations, particularly endocrine disorders, including hypophysitis. While the incidence of hypophysitis is higher with anti-CTLA-4 agents, we report a case of autoimmune hypophysitis induced by anti-PDL1 therapy.
Case Report
A 52-year-old female patient, with no family history of autoimmune diseases, was diagnosed with infiltrating triple-negative breast carcinoma. Immunohistochemical analysis for the anti-PDL1 antibody revealed that more than 75% of tumor cells were positive for this marker. The patient underwent neoadjuvant chemotherapy (paclitaxel and carboplatin) and neoadjuvant immunotherapy (pembrolizumab) before surgery. After six months, she presented with asthenia and pallor, without nausea or abdominal pain. Laboratory tests revealed normal electrolyte levels, but morning cortisol was low at 1.87 ng/ml, with ACTH <1.5 pg/ml. Thyroid function tests showed FT4 at 10.2 pmol/l(normal range: 12–22) and TSH at 2.46 mIU/l,with normal prolactin levels. Autoimmune markers, including ANA, anti-smooth muscle antibodies, and anti-TPO antibodies, were negative. Hypothalamic-pituitary MRI showed no abnormalities in the pituitary stalk or gland. The patient was started on hormone replacement therapy for corticotropic and thyrotropic deficiencies.
Conclusion
Understanding the endocrine side effects of immunotherapies is crucial and must be promptly diagnosed, as they can significantly impact the patient's prognosis and, in some cases, may be life-threatening.

Acute total visual loss complicating macroprolactinoma apoplexy

Khadija Had[1], Bilel Ben Amor[1], Ines Bayar[1], Sana Abid[1], Ekram Hajji[1], Héla Marmouch[1], Hanene Sayadi[1] & Inès Khochteli[1]
[1]Fattouma Bourguiba University Hospital, Endocrinology Department, Monastir, Tunisia

Introduction
Prolactin-secreting adenomas are benign tumors caused by the proliferation of lactotroph cells in the pituitary gland. They account for 60% of pituitary adenomas. Pituitary apoplexy is a rare serious event defined as bleeding or infarction occurring within a pituitary adenoma. Here, we present the case of acute visual loss due to sudden prolactinoma apoplexy.
Case report
A 48-year-old patient with no notable medical history was admitted for retro-orbital headaches, asthenia, and weight loss. On physical examination, no oculomotor dysfunction or visual acuity loss was found. An MRI of the hypothalamic-pituitary region was performed revealing a sellar and suprasellar expansive process measuring 41.6 × 35.9 × 34.6 mm, enlarging the sella turcica and compressing the optic chiasm, bulging inferiorly into the sphenoidal sinus and extending laterally into the cavernous sinuses, encompassing both carotid arteries. Suddenly, the patient's condition worsened, with increasing headaches, vomiting, acute total visual loss, right ptosis, and complete right ophthalmoplegia. A brain CT scan was urgently performed, revealing an 18 mm thick right temporal extradural collection and intra-lesional hemorrhage. The patient underwent emergency trans-sphenoidal surgery. The histopathological examination revealed a partially necrotic and hemorrhagic pituitary adenoma with immunohistochemical expression of prolactin. The patient has retained bilateral blindness with corticotropic, gonadotropic, and thyrotropic insufficiency.
Discussion
Pituitary apoplexy is defined as the occurrence of massive necrotic-hemorrhagic changes within a pituitary adenoma. Considered a medical emergency, its frequency remains rare (0.6% to 5% of patients undergoing surgery for pituitary pathology). Most often, pituitary apoplexy is the initial manifestation of an undiagnosed adenoma, but it can also complicate a known adenoma, as in the case of our patient. The clinical presentation of pituitary apoplexy is characterized by the sudden onset of oculomotor paralysis or visual disturbances, sometimes leading to blindness, accompanied by headaches and, occasionally, altered consciousness. Predisposing factors include pregnancy, treatment with dopamine agonists, and stimulation tests. However, no predisposing factors were identified in our patient. Urgent hormone replacement therapy and transsphenoidal tumor resection usually lead to favorable outcomes, which was not the case for our patient.
Conclusion
Pituitary apoplexy is a rare complication, often revealing a macroadenoma, that threatens both life and functional prognosis, requiring emergency management.

Endocrinological evaluation and natural course of symptomatic paediatric patients with rathke cleft cysts

Ayse Nurcan Cebeci[1], Michaela Marx[1], Regina Trollmann[1], Michael Buchfelder[1], Helmuth-Guenther Doerr[1] & Joachim Woelfle[1]
[1]Friedrich Alexander University, University Hospital, Department of Paediatrics and Adolescent Medicine, Erlangen, Germany

Background and Aim
Rathke cleft cysts (RCC) are usually asymptomatic in childhood and are often diagnosed incidentally on cranial imaging. We aimed to analyse the presenting symptoms, endocrine evaluation, and natural course of our symptomatic patients with RCC.
Methods
We identified 14 patients (8 male, 6 female) with RCC via the university hospital's database and extracted the clinical data from the medical files. The retrospective study covered a period from 2005 to 2023.
Results (median, min-max)
The diagnosis of RCC was made by magnetic resonance imaging at 11.0 (1.8 - 17.6) years. The presenting symptoms were headaches [alone (n = 1) or in combination with nausea/fatigue (n = 2), polydipsia (n = 2) or dizziness (n = 3)] followed by short stature/growth retardation [alone (n = 4) or with polydipsia (n = 1)]. One patient had a syncope with a papilledema. The endocrinological evaluation revealed pituitary insufficiency in 10 children. Growth hormone (GH) deficiency was diagnosed in five patients [isolated (n = 1) or in combination with arginine vasopressin (AVP) deficiency (n = 1) or with central hypothyroidism/-hypocortisolism (n = 3)]. AVP deficiency was found in 5 patients [isolated (n=1), or in combination with central hypothyroidism (n = 2), or hypocortisolism (n = 2)]. Three patients had hyperprolactinemia. Nine patients were treated conservatively (n = 4: no medication; n = 4: hGH, alone or in combination with L-T4 and hydrocortisone, n = 1: desmopressin). Five underwent surgery (transcranial 1; transsphenoidal 4). In the conservatively treated patients, cyst size remained unchanged in 7 and decreased in 2. Of the five patients treated surgically, the cyst size increased in 4; three required a second operation. At the last presentation, after a follow-up period of 6.4 (0.33-14.8) years, the hormone status of conservatively treated patients was normal in 6 and pathological in 3. Five patients (4 m, 1 f) developed hypogonadotropic hypogonadism, including two children who were only treated conservatively.
Conclusions
In our cohort, neurological disorders were the most common reason for the initial presentation. Endocrine evaluation revealed pituitary insufficiency in 10/14 children, with GH- and AVP deficiencies being the most common findings. Regular imaging and endocrine follow-ups are necessary due to the potential for changes in cyst size and hormonal findings.

Real-world characteristics and treatment patterns of adults receiving long-acting growth hormone: insights from the INSIGHTS-GHT registry

Ilonka Kreitschmann-Andermahr[1], Christian J. Strasburger[2], Joachim Woelfle[3], David Pittrow[4], Christine Pausch[4], Heide Sommer[5], Günter Stalla[6], Wolfram Karges[7], Christine Streetz van-der-Werf[7] & Dirk Schnabel[8]

Introduction
Long-acting growth hormone (LaGH) has been developed to improve treatment adherence and patient convenience compared to daily GH injections. In adults with growth hormone deficiency (GHD), LaGH therapy aims to restore physiological GH levels, supporting metabolic health, body composition, and overall well-being. While clinical trials have demonstrated the efficacy and safety of LaGH, real-world data on its use in adult patients remain limited.
Methods
The Investigating Significant Health Trends in Growth Hormone Treatments (INSIGHTS-GHT) registry is an ongoing, German multicenter, observational study designed to collect real-world evidence on the characteristics, treatment patterns, effectiveness, and safety of GH therapy in patients with GHD. Here, we provide an overview of adult patients receiving LaGH within the registry at an interim analysis, dated January 10th, 2025, with a focus on baseline characteristics and initial treatment patterns.
Results
A total of 25 adult patients with GHD receiving LaGH therapy were included. The mean age at GHD diagnosis was 23.2 years (SD: 19.1; range: 0.8–60.8), while the mean age at LaGH initiation was 39.4 years (SD: 16.0; range: 18.3–73.9). Half of the patients (n = 12, 50.0%) had childhood-onset GHD. Regarding sex distribution, 9 patients (36.0%) were male, and 16 (64.0%) were female. The majority had organic GHD (n = 21, 84.0%), while 4 patients (16.0%) had idiopathic GHD. Most patients (n = 24, 96.0%) transitioned from prior daily GH therapy, with a mean duration of previous treatment of 12.8 years (SD: 8.0). The initial LaGH dose was below the recommended level in 6 patients (31.6%), at the recommended level in 11 patients (57.9%), and above the recommended level in 2 patients (10.5%).
Conclusion
This analysis from the INSIGHTS-GHT registry provides first real-world insights into the characteristics and treatment patterns of adults receiving LaGH. The data show that most patients had organic GHD, with a significant proportion transitioning from prior daily GH therapy. While the majority initiated LaGH

at the recommended dose, some started at lower or higher doses, highlighting variability in treatment approaches. The number of patients in the INSIGHTS registry with LAGH therapy can be seen as an indication of its acceptance by patients and prescribers. Since the analyses are continuously updated, INSIGHTS-GHT offers an excellent research platform for investigating these and other aspects of somatotropin therapy.

Introduction

Pituitary neuroendocrine tumours (PitNETs) are relatively common intracranial neoplasms that typically exhibit indolent behaviour. However, some tumours can be clinically aggressive, as indicated by early and frequent recurrences and resistance to standard treatments.

Aim

This study aims to characterise the clinicopathological data of patients with aggressive pituitary tumours (APTs) at a tertiary referral centre and to analyse the effectiveness of different treatment modalities.

Methods

This retrospective study included patients who met the following criteria: radiological evidence of invasive tumour growth (signs of infrasellar extension or parasellar growth classified with a Knosp grade of $\geq$ 3); a histopathological diagnosis of pituitary adenoma with increased proliferative activity defined by a Ki-67 index of $\geq$ 3%; (and, if available, a mitotic count $\geq$ 2 per high-power field); rapid tumour growth; and resistance to standard medical and surgical therapies. We analyzed demographic data and results from hormonal and radiological examinations, data presented as mean $\pm$ SD.

Results

From a total of 1,595 patients who underwent pituitary surgery between 2008 and 2023, we identified 20 patients (8 females and 12 males) with aggressive pituitary tumours based on the inclusion criteria defined above. The mean follow-up duration for these patients was 94.1 $\pm$ 71.8 months. The average age at diagnosis was 44.0 $\pm$ 13.78 years. Among these cases, five patients were later reclassified as having pituitary carcinoma due to the detection of metastasis. All patients had macroadenomas, with the largest tumour diameter measuring 33 $\pm$ 12 mm. Of these patients, fifteen had hormonally active tumours, presenting as follows: Cushing's disease ($n = 6$), hyperprolactinaemia ($n = 5$), acromegaly ($n = 3$), and hyperthyroidism ($n = 1$). The total number of surgical interventions performed on these patients was 53. The median Ki-67 index was 7% (range: 3-40) and mitotic count was 4 per high-power field (range: 2-20), respectively. Fifteen patients (75%) received pituitary irradiation. The number of pituitary surgeries per patient per year was significantly lower after radiotherapy (0.39 $\pm$ 0.10 vs. 0.13 $\pm$ 0.05; $P = 0.001$). At least on short term, temozolomide treatment resulted in partial tumour remission in 3 out of 4 patients. Three metastatic and three non-metastatic patients died due to pituitary disease progression.

Conclusion

In our endocrine centre 1.3% of patients in the surgical pituitary tumour series have aggressive tumours. The study found that fewer surgical interventions were required after radiotherapy for these aggressive tumours. This finding reinforces current guidelines recommending earlier radiotherapy for pituitary adenomas when aggressive features are present.

Central precocious puberty in a female child with a giant hypothalamic hamartoma: diagnosis and treatment

Maria Francesca Messina[1], Francesca Granata[2], Tiziana Abbate[1], Sergio Vinci[2] & Malgorzata Wasniewska[3]

[1]University of Messina, Unit of Pediatrics, Department of Human Pathology, Messina, Italy; [2]University of Messina, Unit of Neuroradiology, Department of Biomorfology, Messina, Italy; [3]University of Messina, Unit of Pediatrics, Department oh Human Pathology, Messina, Italy

Hypothalamic hamartoma (HH) is a rare, congenital, and benign lesion often arising from the floor of the hypothalamus involving either tuber cinereum or mammillary bodies and its prevalence varies between 1/50,000 and 1/200,000 persons. The classical signs are: central precocious puberty (CPP), gelastic seizure, and developmental delay. It is usually diagnosed by brain magnetic resonance imaging (MRI) scans and is seen as non-enhancing, isointense, or hyperintense lesions on T2-weighted images. HH is one of the most common organic causes of CPP that tends to occur significantly earlier than idiopathic CPP but it is well managed by gonadotropin releasing hormone (GnRH) agonist. We present the case of a female child who was referred to our Unit of Pediatric Endocrinology for premature thelarche. She was 3 years-old, and on physical examination showed: height 106.7 cm (+ 3.0 SDS), mid-parental height 163.0 cm (0.1 SDS), weight 24.5 kg (+ 3.7 SDS), Tanner stage B2-3, P1, no dysmorphic features. Diagnostic work-up showed: bone age 7.9 yrs (Greulich-Pyle), basal FSH 14.2 mIU/ml, basal LH 8.2 mIU/ml, estradiol 29.7 pg/ml, LH peak of GnRH-stimulation test 29.1 mIU/ml, IGF-1 262 ng/ml, beta-HCG and alfa-fetoprotein negative, pelvic ultrasound (peripubertal uterus with longitudinal diameter 36.9 mm and large ovaries $>$ 3 cc with follicles). Brain MRI scans evidenced a neoformation of oval morphology and dimensions of approximately 9 $\times$ 12 $\times$ 10 mm, inseparable from the middle third of the hypothalamic infundibulum, with a median location, and projecting into the context of the suprasellar cisterns; the finding was compatible with hamartoma of the tuber cinereum. The adenohypophysis had maximum dimensions of approximately 15x4x4 mm. There were no appreciable signal alterations of the gland in both conditions baseline and after gadolinium administration. Pituitary peduncle was aligned. Since the child had never presented seizures and no indication were for surgical intervention we prescribed medical treatment with Leuprorelin (3.75 mg every 28 days intramuscularly). Six months after starting therapy the child had never experienced any side effects and thelarche had regressed. Our case confirms that children with very early presenting CPP deserve a brain MRI because the risk of an organic lesion is very high. We believe that tall stature should be considered a clue element to differentiate isolated premature thelarche and precocious puberty and when bone age is significantly accelerated, it is mandatory to carry out all the appropriate investigations for the correct diagnosis.

Rathke's cleft cyst presenting with isolated arginine vasopressin deficiency

Joanna Sobolewska[1], Wioleta Respondek[2], Grzegorz Turek[3], Lukasz Dzialach[4] & Przemysław Witek[4]

[1]Medical University of Warsaw, Department of Internal Medicine, Endocrinology and Diabetes, Warsaw, Poland; [2]Mazovian Brodnowski Hospital, Department of Internal Medicine, Endocrinology and Diabetes, Warsaw, Poland; [3]Postgraduate Medical Centre, Mazovian Brodnowski Hospital, Department of Neurosurgery, Warsaw, Poland; [1]Medical University of Warsaw, Department of Internal Medicine, Endocrinology and Diabetes, Warsaw, Poland

Introduction

Rathke's cleft cyst (RCC) is a benign, non-neoplastic lesion located in the sellar and suprasellar region of the brain, with a prevalence of 12-33% of cases. It constitutes a remnant of Rathke's pouch - an embryonic precursor of the pituitary gland. While most RCCs appear asymptomatic, headaches, visual disturbances, mass effect-related hypopituitarism, and hyperprolactinemia due to the "stalk effect" phenomenon may occur. Arginine vasopressin deficiency (AVP-D), characterized by impaired hypothalamus/posterior pituitary vasopressinergic neurons, resulting in dysfunction in AVP synthesis, typically does not represent the clinical picture of an RCC patient.

Case report

A 25-year-old female with a history of severe headaches (NRS 5-9 points) was referred to the Department of Endocrinology for hormonal evaluation of a sellar

lesion visualized in an outpatient head magnetic resonance imaging (MRI). She had a history of polyuria, polydipsia, and unintentional weight gain (10kg in 2-3 months). On physical examination, the patient was in general good condition, without features of endocrine stigmatization. Hormonal evaluation revealed normal prolactin levels (triplicate determinations), including after dilution, and preserved appropriate function of the pituitary tropic axes. Additional testing indicated decreased urine specific gravity (USG) and osmolality, increased plasma osmolality, which, along with polydipsia and polyuria (7700 mL/day), led to the suspicious of AVP-D. Other clinical causes and the drug effect have been excluded. Desmopressin (DDAVP) treatment was initiated, the dosage was set individually according to symptoms and plasma osmolality. A follow-up head MRI identified significant progression of the sellar mass dimensions - 14 (CC) × 12 (AP) × 17 (DB) mm, high-intensity in T1 and T2-weighted images, adhesion to the medial cavernous sinuses' walls and modeling of the optic chiasm. On ophthalmological evaluation, the patient had no significant visual field abnormalities. She was consulted neurosurgically and, upon informed consent, qualified for surgery. In hydrocortisone protection, transsphenoidal endoscopic resection of the pituitary lesion was performed. The procedure was uncomplicated. A normal postoperative image with complete resection was confirmed in head computer tomography and MRI. Clinically, the patient did not develop cerebrospinal fluid leakage. Histopathological verification revealed RCC. In the postoperative evaluation (performed without DDAVP usage), the patient presented adequate urine output, with normal USG and plasma osmolality.

Conclusions

Given the concerns about determining the appropriate management of mildly symptomatic RCC, it seems crucial to consider AVP-D as a clinical manifestation.

Osilodrostat effectiveness in the treatment of cushing's disease (CD) and ectopic cushing's syndrome (ECS)- a single-center real-life experience

Aleksandra Gamrat-Żmuda[1,2], Martyna Więcławek[3], Mari Minasyan[1], Ewelina Rzepka[1], Anna Bogusławska[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]

[1]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Doctoral School of Medical and Health Sciences, Jagiellonian University Medical College, Krakow, Poland; [3]Students Scientific Group of Endocrinology, Jagiellonian University Medical College, Krakow, Poland.

Introduction

Osilodrostat, approved in 2020, is a second-line therapy for Cushing's syndrome (CS) when surgery is ineffective, contraindicated, or as bridging therapy before surgery. While urinary free cortisol (UFC) is the standard for assessing treatment efficacy, prolonged processing time can limit its utility.

Objectives

Retrospective assessment of the efficacy of osilodrostat therapy in CS patients from a single reference endocrinology center by assessing the reduction of serum cortisol levels and the impact on CS complications.

Materials and Methods

We analyzed medical records of 25 CS patients treated with osilodrostat (2020-2025). Due to UFC processing delays (>7 days), response was assessed based on morning serum cortisol and clinical parameters. We evaluated time to reduce:.

- serum cortisol concentration(CR)- time to 50% cortisol reduction or achieve level <15 μg/dl.
- potassium supplementation(PS) - any reduction.
-antihypertensive(aHT) and antidiabetic therapy(aDT) - any reduction.

Results

Of 23 analyzable patients (13 CD, 10 ECS), mean diagnosis age was 57.8 years; 61% were women. Seven (30.4%) died. Mean morning serum cortisol at diagnosis: 42.7 μg/dl; ACTH: 180.3 pg/ml. Osilodrostat was first-line in 11, second-line in 10 (after metyrapone, ketoconazole, or pasireotide), and third/fourth-line in 2. Treatment was changed to osilodrostat in 7/12 cases due to incomplete clinical/biochemical remission, in 1/12 due to intolerance, and in 4/12 after short-term use of another drug as a bridge before osilodrostat. Four patients received a "block and replace" regimen, including two with cyclic CS. At osilodrostat initiation: 17 required potassium supplementation (9 needed spironolactone), 19 had diabetes (9 on insulin), 21 had hypertension. Mean treatment duration: 221.5 days (CD), 156 days (ECS). CR was achieved in 22/23 patients at a mean dose of 7.2 mg/day (5.8 mg in CD; 9.5 mg in ECS).

Key outcomes

	Time to reduce(TtR)in days (number of patients with the effect)	
	CD $n = 13$	ECS $n = 10$
-TtR serum cortisol concentration(CR)	28.8(13/13)	9.2(9/10)
-TtR potassium supplementation	54.9(8/8)	8.9(10/10)
-TtR hypertension therapy	55.1(10/11)	21.7(9/10)
-TtR diabetes therapy	28.8(6/11)	28(3/8)

Dose of osilodrostat was negatively moderately correlated with time to reduction of aHT and aDT ($r = -0.65$ ($P = 0.003$) and -0.7 ($P = 0.05$)). One CD patient developed an adrenal crisis, leading to transient treatment discontinuation.

Discussion

Morning serum cortisol combined with clinical assessment is effective for monitoring osilodrostat treatment. In ECS, the most rapid improvement was seen in potassium supplementation reduction. Higher doses of osilodrostat were associated with faster improvements in blood pressure and glycemic control. There is the necessity of further research to optimize and personalize osilodrostat therapy.

GH secretion inhibition test in children - should we use different standards for obese children vs. normal weight children?

Paula Smalczewska[1], Renata Stawerska[1,2], Marzena Kolasa-Kicińska[1], Krzysztof Jeziorny[1,2], Anna Łupińska[1,2], Joanna Krasińska[1], Angelika Pakuła[1], Sylwia Rajewska[1], Maciej Hilczer[1] & Arkadiusz Zygmunt[1,3]

[1]Polish Mother's Memorial Hospital - Research Institute of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [2]Medical University of Lodz, Department of Paediatric Endocrinology, Lodz, Poland; [3]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland.

Hyperglycemia causes strong inhibition of growth hormone (GH) secretion. This phenomenon is used in the diagnosis of suspected GH excess during the GH suppression test after oral glucose administration (OGTT). In our previous work, we determined that the discriminant value for normal GH suppression during this test is < 1.1 ng/ml, and this nadir occurred at each of the assessed time points. Recently, there has been discussion about the influence of obesity on the interpretation of GH secretion in stimulation tests and the need to use different (lower) norms for people with obesity. The aim of this work was to present the results of GH concentration during the suppression test performed in children with obesity (in whom OGTT was performed for other reasons, and gigantism was excluded.

Material and Methods

A group of 171 children aged 4 to 17.2 years with various endocrine disorders was divided into 2 subgroups based on the SDS BMI index. The group of children with normal body weight (SDS BMI in the range of -2.0 to 2.0) included 57 people (40 girls and 17 boys). The group of children with excessive body weight (SDS BMI > 2.0) included 114 patients (66 girls and 48 boys). In each child, OGTT was performed after the administration of glucose at a dose of 1.75 g/kg (max. 75 g) with the assessment of glucose and GH concentration at time points 0, 30, 60, 90 and 120 minutes. In children, gigantism was excluded - based on the normal IGF-1 concentration or higher IGF-1 with exclusion of the presence of pituitary adenoma in MRI examination with contrast.

Results

In the subgroup of children with normal body weight, the minimum GH concentration during the test (from 0 to 120 minutes) ranged from 0.07 to 1.05 ng/ml, and the maximum - from 0.05 to 13.74 ng/ml. In the subgroup of children with obesity, the minimum GH concentration during the test ranged from 0.02 to 1.07 ng/ml, and the maximum from 0.11 to 17.29 ng/ml. In both groups, there were no statistically significant differences between the lowest GH concentrations (nadir).

Conclusion

If it is necessary to perform a suppression test in a child with obesity, it seems that the same cut-off point should be used to exclude gigantism; i.e. GH level < 1.1 ng/ml occurring in at least one of the 5 time points of the suppression test after oral glucose administration.

Prolonged adrenal insufficiency following osilodrostat discontinuation

Sonia Kaniuka-Jakubowska[1], Michał Kunc[2], Maria Maksymowicz[3], Mariusz Łapiński[4], Anna Kowalczyk[5], Przemysław Kłosowski[1], Michał Szulc[1], John Wass[6] & Renata Świątkowska-Stodulska[1]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Diseases, Gdańsk, Poland; [2]Medical University of Gdansk, Department of Pathomorphology, Faculty of Medicine, Gdansk, Poland; [3]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Cancer Pathomorphology, Warsaw, Poland; [4]University Clinical Centre in Gdansk, Department of Thoracic Surgery, Gdansk, Poland; [5]Medical University of Gdansk, Department of Oncology and Radiotherapy, Faculty of Medicine, Gdansk, Poland; [6]Oxford University Hospitals NHS Foundation Trust, Department of Endocrinology at the Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom

Osilodrostat is an oral steroidogenesis inhibitor used to treat hypercortisolism by inhibiting 11-beta-hydroxylase. It can cause adrenal insufficiency (AI) in about 40% of patients, which is typically considered a natural consequence of therapy. However, along with a few early reports, suggest that AI can persist even after discontinuation of osilodrostat.[1, 3, 5] We present the case of a 74-year-old female patient with ectopic ACTH-dependent Cushing's syndrome who developed prolonged AI despite the withdrawal of osilodrostat. The patient underwent radiotherapy for a primary lesion located in the anterior mediastinum. During treatment, osilodrostat was introduced (2-4 mg/d), and adrenal insufficiency developed within four weeks. She required hydrocortisone replacement therapy, and over time, undetectable morning cortisol levels were observed. After reducing morning serum cortisol levels, osilodrostat dose was decreased and withdrawn 15 months into therapy. Despite 31 weeks off the drug, morning cortisol remained undetectable, with no response to a high-dose ACTH test, and the patient required ongoing hydrocortisone substitution. Discussion of prolonged AI after osilodrostat discontinuation should mention a study presenting reduced adrenal size (despite stable ACTH levels), suggesting a potential adrenolytic effect of the drug.[4] Another case report decscirbe decrease in 11-deoxycortisol in prolonged AI after osilodrostat treatment.[1] Given the drug's mechanism, 11-deoxycortisol levels should increase due to inhibited conversion to cortisol. However, also in the LINC 3 study, after an initial rise, despite remaining above reference ranges, the levels declined during follow-up.[2] Another aspect is the observed increase in AI from week 48 to week 72 during osilodrostat treatment in a clinical trial which may suggest the link to the mechanism seen in our and previous cases.[2] The mechanism of prolonged AI after osilodrostat discontinuation is not yet understood. Case reports are needed to raise awareness, potentially prompting further research to clarify these effects and explore broader therapeutic applications.

Body composition analysis in children treated with recombinant GH

Ioana Maria Vlasa[1], Raluca Pop[1] & Maria Ionela Pascanu[1]
[1]George Emil Palade University of Medicine, Pharmacy, Sciences and Technology of Targu Mures, Targu Mures, Romania.

Background

Growth hormone effect on body composition is well recognized and treatment with recombinant growth hormone (rGH) has a positive impact.

Aim

The aim of this study was to analyze changes in body composition parameters under rGH treatment in children diagnosed with short stature and to investigate potential influencing factors.

Material and Methods

A secondary data analysis was conducted in the Endocrinology Compartment of the Mures County Hospital, Romania, approved by the local Ethics Committee. All children diagnosed with short stature and receiving rGH treatment were eligible for inclusion if they had four body composition analyses at least 6 months apart. The variables analyzed included age, gender, environment, ethnicity, age at treatment start, mean rGH dose, treatment duration before first analysis, the interval between analysis, height and body mass index (BMI) SDS, body composition parameters assessed by bioimpedance (body fat, truncal fat, muscle mass, skeletal muscle mass percentages, angle phase, and sarcopenic index) and family related variables (BMI, educational level, family income). Statistical analysis was performed using SPSS v.25 with a level of significance $\alpha = 0.05$.

Results

Thirty children were included with a mean age of 7.75 ± 3 years and a gender ratio close to one (1,14:1). There was no statistically significant trend in body composition parameters taken during serial measurements, except for the sarcopenic index and height ($P < 0.001$). Environment, ethnicity, age at treatment start, and family-related variables had no significant influence on body composition changes. Gender differences in body composition revealed that the change in muscle mass ($P = 0.009$) and skeletal muscle mass ($P = 0.013$) was statistically significantly higher for boys, and body fat ($P = 0.013$) for girls. Sarcopenic index changes correlated with height gain ($r = 0.483$, $P = 0.007$) and BMI changes ($r = 0.491$, $P = 0.006$), while angle phase correlated with changes in muscle mass ($r = 0.488$, $P = 0.006$), skeletal muscle mass ($r = 0.474$, $P = 0.008$) and mean rGH dose ($r = -0.390$, $P = 0.033$). In linear regression analysis with body composition parameters as dependent variables, puberty progression, age, age at treatment start, and duration of treatment were significant predictors for sarcopenic index change, with the model explaining 32,3% of the variation, albeit non-significant. There was no difference in body composition changes regardless of the indication for treatment.

Conclusions

Gender and pubertal status play a significant role in body composition changes while rGH seems to play a less significant role, regardless of the indication for treatment.

Keywords

short stature, bioimpedance, gender, pubertal status, rGH treatment.

Impact of early menarche on adolescent health

Semra Bahar Akın[1], Ilker Tolga Özgen[2] & Yasar Cesur[3]
[1]Derince Training And Research Hospital, Department of Pediatrics, Division of Pediatric Endocrinology, Kocaeli, Türkiye; [2]Biruni University, Faculty of Medicine Department of Pediatrics, Division of Pediatric Endocrinology, Istanbul, Türkiye; [3]Bezmialem Vakif University, Department of Pediatrics, Division of Pediatric Endocrinology, Faculty of Medicine, Istanbul, Türkiye.

Aim

Patients who begin menarche between the ages of 9.5 and 11 do not initiate treatment. It is acknowledged that early menarche may adversely impact height. The onset of menarche at an early age affects the menstrual cycle, induces psychological repercussions in individuals, and leads to menstrual irregularities. Our study investigated the adverse impacts of early menarche on the menstrual cycle, psychological health, and final height.

Methods

This retrospective analysis involved children aged 9.5 to 11 years who consulted the pediatric endocrinology outpatient clinic for menarche from January 2012 to January 2018. The target height (TH) was determined from the patients' outpatient clinic assessment files, utilizing medical records at the beginning of treatment. The final height (FH) and weight of the patients were documented via a questionnaire. The TH and FAH of girls were compared across groups. We performed a paired t-test to assess the difference between TH and FAH. The study examined menstrual patterns, menstrual cycles, dysmenorrhea, duration of menstrual regularity, and a history of psychiatric disorders required pharmacological treatment.

Results

The patients' TH was 159.27 ± 4.52cm, FAH was 157.71 ± 5.19cm, target height SDS was 0.64 ± 0.76, and final height SDS was 0.81 ± 0.91. It was observed that 6 of the 11 patients who gained more than -1 SDS compared to the target height were accompanied by chronic disease, and those who gained more than $+1$ SDS compared to the target height were not accompanied by chronic disease($P = 0.014$). Ten patients (17.2%) used medication due to asthma, and 9 patients (15.5%)used medication due to menstrual irregularity. Painful menarche was found in 50% of the patients ($n = 26$). Early menarche was present in the families of 24.1% of the patients ($n = 14$). Psychiatric disorders were observed in 22.4% ($n = 13$) of early menarche cases. 15.5% ($n = 9$) of the patients were receiving

medication for psychiatric illness. The average duration of menstruation was 6.13 ± 2.11 days, the need for pads was 3.74 ± 0.82 pieces/day, and the time to regularization was 9.18 ± 9.95 months.
Conclusion
Though some studies assert that early menarche negatively impacts height, our research revealed no detrimental influence of early menarche on final height. The concurrent chronic disease negatively affected growth, leading to a -1 SDS deviation from the target height. The correlation between asthma and early menarche was significant. The requirement for psychiatric treatment increased far above population averages. We claim that the existence of a comorbid condition adversely impacts growth, regardless of whether early menarche has a definitive influence.

Case report of ependymal pituicytoma

Mehmet Yigit[1], Hatice Ozisik[1], Gökçen Ünal Kocabaş[1], Ezgi Ulas[1], Melih Bektas[1], Aysel Mammadyarzade[1], Yesim Ertan[1,2], Erkin Ozgiray[1] & Banu Sarer Yurekli[1]
[1]Ege University, Endocrinology, İzmir, Türkiye; [2]Ege University, Pathology, İzmir, Türkiye.

Background
Pituitary pituicytoma is a rare, low-grade primary tumor originating from pituicytes in the neurohypophysis or infundibulum. Clinically, it presents with symptoms similar to other sellar region tumors, such as visual impairment, headache, and/or pituitary hormone deficiencies, depending on tumor size. Immunohistochemical examinations are crucial for diagnosis.
Case Presentation
A 63-year-old male patient with a history of basal cell carcinoma and squamous cell carcinoma, previously treated at another center, presented to our clinic due to visual disturbances. Pituitary MRI revealed a well-defined, lobulated, solid mass measuring 17 × 15 × 10 mm in the sella, extending to the optic chiasm and involving the infundibulum, consistent with a pituitary macroadenoma. Physical examination showed bitemporal hemianopsia without motor deficits or pathological reflexes. Preoperative laboratory tests, including liver, kidney, and thyroid function tests, as well as a complete blood count, were within normal limits. The patient had no history of regular medication use, Anterior pituitary hormone levels were appropriate for his age. The patient underwent surgery at our neurosurgery department, and histopathological examination demonstrated a diagnosis of WHO grade 1 pituicytoma, specifically an ependymal pituicytoma. Immunohistochemical staining showed positive TTF-1, Ki-67 of 1%, and negative staining for S-100, synaptophysin, GFAP, and anterior pituitary hormones. Postoperatively, the patient's visual symptoms improved, and follow-up evaluations displayed normal anterior pituitary hormone levels with no need for additional treatment.
Conclusion
According to the World Health Organization (WHO) classification, pituicytoma is a benign grade 1 tumor of the pituitary gland. It is challenging to diagnose due to its clinical and radiological similarities to other sellar region masses. The presence of a posterior pituitary lesion on MRI may suggest pituicytoma; however, immunohistochemical analysis is essential for a definitive diagnosis. To prevent recurrence, total surgical resection of the tumor is critical.

Not just the skin rash: a case of coexistence of macroprolactinoma and metastatic neuroendocrine tumour

Thinn Thinn Yu[1] & Rebecca Gorrigan[2]
[1]Specialist Registrar in Endocrinology and Diabetes, St Bartholomew's Hospital, Barts Health NHS Trust, London, United Kingdom; [2]Consultant in Endocrinology and Diabetes, St Bartholomew's Hospital, Barts Health NHS Trust, London, United Kingdom.

Introduction
Hyperprolactinemia is a common finding in patients on antipsychotic medications. Markedly elevated prolactin levels warrant further investigation.
Case Presentation
A 57-year-old woman with schizophrenia on risperidone was referred to the endocrinology clinic after routine testing revealed asymptomatic hyperprolactinemia. She had no headaches, or visual disturbance and was 2-years post-menopause. Her main concern was a 3-year history of progressive large volume, watery diarrhoea associated with 12kg weight loss and a hyperpigmented rash. She denied flushing, wheezing, or symptoms of hypoglycaemia. She had been previously investigated with a normal colonoscopy and been diagnosed with irritable bowel syndrome. She had type 2 diabetes and had no family history of endocrinopathy. On examination, she had no clinical endocrinopathy. Skin examination revealed well-demarcated, hyperpigmented macules over her gluteal, inner thigh, feet and inframammary regions. The remainder of her clinical examination was normal, including normal visual acuity, eye movements and visual fields to confrontation with a red pin. Laboratory investigations showed a significantly elevated prolactin of 39,393 mU/l(normal range < 496 mU/l)with suppressed gonadotropins. The remainder of her anterior pituitary function and calcium were normal. The prolactin level was too high to be attributed to antipsychotic therapy. Pituitary MRI confirmed a 22 mm macroadenoma with right cavernous sinus invasion but no optic chiasm compression. After psychiatric consultation, risperidone was switched to aripiprazole, leading to an improvement in prolactin levels (9,315 mU/L). Further workup for her diarrhoea and rash revealed elevated 24-hour urinary 5-hydroxyindoleacetic acid (5-HIAA) and chromogranins A and B, with normal fasting gut peptides and glucagon. Imaging, including 68Ga-DOTATATE PET-CT and triple-phase CT, identified a primary ileal neuro-endocrine tumour (NET) with mesenteric, liver, and lung metastases. Echocardiography showed no evidence of carcinoid heart disease and genetic testing for multiple endocrine neoplasia type 1 (MEN1) was negative. Histology confirmed a Grade 1 NET (Ki67 < 3%). She was initiated on 4 weekly Lanreotide injections and vitamin B complex, resulting in a significant reduction in diarrhoea and resolution of her rash, with normalisation of 24-hour urine 5HIAA.
Learning Points
1. While drug-induced hyperprolactinemia is common, significantly elevated prolactin levels necessitate further evaluation to exclude pituitary adenomas.
2. Aripiprazole is an atypical antipsychotic, which is effective at reducing serum prolactin and pituitary adenoma size when dopamine agonist therapy is contra-indicated. This is an off-license use.
3. The combination of diarrhoea and a rash should alert the physician to the possibility of an underlying neuro-endocrine tumour.

JOINT2559

A rare coexistence of acromegaly with metastatic adrenocortical carcinoma

Manoj Dodiya[1], Pratibha Natesh[1], Amjad Shad[1], Ian Brown[1], Hiten Mehta[1], Martin O. Weickert[1] & Harpal Randeva[1]
[1]University Hospital Coventry and Warwickshire, Department of Endocrine and Diabetes, Coventry, United Kingdom.

Background
Adrenocortical carcinoma (ACC) is a rare endocrine malignancy often with an unfavourable prognosis. The coexistence of acromegaly and ACC is quite rare. Here we describe a case of metastatic ACC in a patient who had Acromegaly treated with surgery, radiotherapy, and medical management.
Case
A male in his late 30s was referred to the endocrine department in 2018 to investigate for change in facial appearance. He was biochemically confirmed to have acromegaly, a 33 mm pituitary macroadenoma with bilateral cavernous invasion. He underwent transsphenoidal adenectomy and histology revealed somatotroph adenoma of partially granulated type with Ki-67 index of 3-5 %. Post-operatively, he had a biochemical recurrence of acromegaly along with panhypopituitarism and residual tumour in the left cavernous sinus. Hence, he was commenced on lanreotide 120 mg monthly injections. His IGF-1 failed to control on lanreotide and was then offered 25 sessions of pituitary radiotherapy in 2019. Subsequently, he was started on pegvisomant injections in 2021 due to suboptimal IGF-1 control following which IGF-1 levels were controlled. In 2023, while being continued on pegvisomant, he was noted to have progressive lower limb swelling, weight gain and deranged liver function tests. Therefore pegvisomant, lanreotide and hydrocortisone were discontinued. Detailed evaluation revealed non-suppressed plasma cortisol (1593 nmol/L), significantly raised urine cortisol (> 5000 nmol/l)and suppressed ACTH. Abdominal imaging revealed a right adrenocortical mass with metastasis, inferior vena cava thrombus, bilateral pleural effusion and ascites. He was initially planned for surgical excision followed by aggressive chemotherapy. However, a repeat CT scan of the adrenal showed rapid tumour progression, and his general condition deteriorated. He was initiated on Mitotane and Metyrapone with hydrocortisone. A multi-disciplinary team concluded that he was not for surgery and palliative care was

the best option. He was initiated on enoxaparin for IVC thrombus, unfortunately, the tumour bled resulting in further deterioration and death. Extensive evaluation for genetic studies revealed negative results for AIP, MEN1, CDC73, CDKN1B, PRKAR1A, RET, VHL genes.
Conclusion
Acromegaly is associated with greater morbidity and a high incidence of tumours, possibly due to the permissive role of elevated GH and IGF-I levels. Adrenal lesions seem more frequent in acromegaly than in the general population, however, no single factor (GH/IGF-I levels or disease duration) predicts them. Certain genetically inherited conditions are associated with aggressive pituitary tumours and ACC. Negative results of frequently mutated gene profiles open a path for more research on novel genetic associations.

A diagnosis not to be missed

Jahard M. Aliaga-Arias[1], Sinan Barazi[1], Simon Aylwin[2], Omar Al-Salihi[3], Safa Al-Sarraj[4] & Eleni Maratos[1]
[1]King's College Hospital NHS Foundation Trust, Neurosurgery Department, London, United Kingdom; [2]King's College Hospital NHS Foundation Trust, Endocrinology Department, London, United Kingdom; [3]Guy's and St Thomas' NHS Foundation Trust, Oncology Department, London, United Kingdom; [4]King's College Hospital NHS Foundation Trust, Neuropathology Department, London, United Kingdom.

New developments in targeted oncological treatment of craniopharyngioma provide innovative perspectives in the management of this challenging pathology. We report a clinical case demonstrating the fundamental role of pathological confirmation and molecular analyses for an optimal up to date treatment of craniopharyngioma. A 53-year-old male presented in August 2024vwith seven months history of visual failure and eventual visual deterioration. The ophthalmology assessment detected reduced visual acuity in both eyes, with OCT and visual field patterns in keeping with chiasmatic lesion. An MRI head demonstrated a suprasellar lesion involving the optic chiasm and the hypothalamus, and extending into the third ventricle, with features suggestive for an optic pathway/hypothalamic glioma. Hormonal testing demonstrated normal pituitary function with no diabetes insipidus. Initial steroid treatment with dexamethasone provided partial improvement of vision and interruption of deterioration. The case was reviewed by a Skull Base MDT and accordingly, the patient underwent a right sided pterional craniotomy in September 2024 and partial resection of suprasellar lesion with intraoperative neuro-monitoring including visual evoked potentials. The microsurgical procedure was recorded with a high-definition images, demonstrating the tumour appearances of a mixed density lesion and multiple fragments were collected for pathological analysis. The early postoperative visual function was overall stable compared to the vision prior to surgery. The integrated histopathology and molecular analyses confirmed a papillary craniopharyngioma WHO grade 1, B-RAF p.V600E mutated. The patient was initiated on a targeted monoclonal treatment combining vemurafenib and cobimetinib, BRAF/MEK inhibitors. The patient had an improvement in vision and the repeat MRI head from January 2025 demonstrated early response to treatment. In conclusion, the case presented demonstrate the relevance of the recent changes in the clinical management of suprasellar lesions, for which currently a pathological molecular confirmation is a cardinal step to guarantee the best oncological and functional outcomes.

Peripheral precocious puberty leading to central precocious puberty due to ovarian sex cord stromal tumor with annular tubules (SCTAT)

Jose Bernardo Quintos[1], Victor Ramirez[1], Bradley DeNardo[1], Elena Puscasiu[2], Dragos Luca[2] & Monica Serrano Gonzalez[1]
[1]Hasbro Children's Brown University Health, Pediatrics/Division of Pediatric Endocrinology, Providence, Rhode Island, United States; [2]Rhode Island Brown University Health, Pathology, Providence, United States.

Objective
Sex cord tumor with annular tubules (SCTAT) is a rare type of sex cord stromal ovarian tumor. We report an 8-year-old female who presented with peripheral precocious puberty (PPP) evolving to central precocious puberty (CPP) after excision of right ovarian tumor due to SCTAT.
Method
Single case report.
Results
She was seen in the endocrine clinic at 6 years and 8 months. She developed thelarche at 5 years and 2 months, pubic hair at 6 years, and vaginal bleeding at 6 years and 7 months. Mid parental target height is 152.3 cm. Pertinent physical examination showed height 134.2 cm (99%), weight 32.7 kgs (98%), Skin: small 0.5 cm irregular café au lait macule on the right buttock, and GU: Tanner IV breast development, Tanner 3 pubic hair. Endocrine evaluation showed LH <0.005 mIU/ml, FSH $<$ 0.3 mIU/ml, estradiol level 121.7 pg/ml, DHEA-S sulfate 37 mg/dl, Anti-Mullerian Hormone 34.3 ng/ml (normal 0.256-6.34), β-HCG $<$ 2 Miu/ml, TSH 0.63 uU/ml, Free T4 1.16 ng/dl, inhibin B 1,250 pg/ml (normal $<$182 pg/ml). Bone age X-ray of the left hand was 10 years. Pelvic ultrasonography showed uterus 6.8 $\times$ 2.7 $\times$ 4 cm and endometrium 12 mm in thickness. The right ovary measured 6.2 $\times$ 3.3 $\times$ 3.5 cm with a 2 $\times$ 4.3 $\times$ 6 cm right ovarian cyst. The left ovary measured 2.6 $\times$ 1.4 $\times$ 1.7 cm. Bone scan was negative for fibrous dysplasia. CT of the abdomen and pelvis showed right ovarian complex cystic mass. CT of the chest was negative for metastasis. She underwent right oophorectomy at 6 years 11 months. Pathology was consistent with right ovarian SCTAT with focal areas with Sertoli cells and juvenile granulosa- like appearance with classification of FIGO 1A without need for adjuvant therapy. Repeat tumor markers were normal. At follow up at 7 1/2 years, she was Tanner 5 breasts and 4 pubic hair. She had CPP with serum LH 1.4 mIU/ml, FSH 6.5 mIU/ml, and estradiol level 12.7 pg/ml. Bone age X-ray of the left hand was 11 years. She was treated with a GnRH agonist.
Conclusion
Most children with SCTAT present with PPP. Our patient progressed to CPP after right oophorectomy necessitating treatment with a GnRH agonist. Close monitoring of pubertal status and hormonal evaluation after surgery is important to detect evolution of potential CPP and manage this appropriately.

BMI impacts on quality of life and endocrine complications in patients with non-functioning pituitary adenomas – A prospective study in patients before and after transsphenoidal surgery

Victor Hantelius[1,2], Gudmundur Johannsson[1,2], Sofie Jakobsson[3,4], Tobias Hallen[3,6], Thomas Skoglund[5,6] & Oskar Ragnarsson[1,2]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]University of Gothenburg Centre for Person-Centred Care (GPCC), Gothenburg, Sweden; [4]Institute of Health and Care Sciences, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [5]Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Department of Clinical Neuroscience, Gothenburg, Sweden; [6]Sahlgrenska University Hospital, Department of Neurosurgery, Gothenburg, Sweden.

Background
Whether Body mass index (BMI) impacts on surgical outcomes and complications in patients with non-functioning pituitary adenomas (NFPA) who undergo transsphenoidal surgery (TSS) has not been explored.
Objective
To assess the influence of BMI on quality of life (QoL) and surgical complications in patients with NFPA.
Methods
Before and 12 months after TSS, BMI, endocrine function, QoL (EQ-5D visual analogue scale (EQ-VAS)), peri- and postoperative complications were assessed in 122 consecutive patients with NFPA. A 5% body weight change was considered significant.
Results
The mean preoperative BMI was 27.9 $\pm$ 4.9, 42 (34%) patients had BMI <25, and 37 (30%) had BMI >30 kg/m^2. Preoperative hypogonadotropic hypogonadism (HH) was more common in patients with BMI >30 compared to those with BMI <25, 57% vs 33%; $P = 0.044$. High BMI was not associated with any perioperative complications. At 12 months after TSS the mean BMI was unchanged (27.9$\pm$5.3, $P = 0.53$), but 19 patients (16%) had lost weight and 17 (14%) had gained weight. A larger portion of patients with BMI >30 had growth hormone (GH) deficiency and HH compared to patients with BMI <25, 70% vs 45%; $P = 0.036$, and 57% vs 26%; $P = 0.01$, respectively. A larger portion of patients who gained weight had central hypothyroidism and adrenal insufficiency compared with those who had lost weight, 71% vs 26%; $P = 0.018$ and 53% vs 11%; $P = 0.010$, respectively. The median EQ-VAS score increased in patients

with BMI <25 from 70.0 (Interquartile range (IQR) 53-80) to 80 (65-93); $P = 0.008$, and in patients who lost weight, from 70 (40-80) to 85 (65-94); $P = 0.007$. In patients with BMI >30, EQ-VAS did not improve (70 [40-85] to 80 [63-90]; $P = 0.426$), nor in patients who gained weight (75 [60-90] to 80 [58-90], $P = 0.460$).
Conclusions
High BMI is common in patients with NFPA and is associated with preoperative HH and postoperative HH and GH deficiency. Adrenal insufficiency and central hypothyroidism occur more frequently in patients who gain weight after TSS. High BMI and increased body weight are associated with less improvement of QoL.

Recurrent primary pituitary abscesses in a young girl: a rare clinical challenge

Amy Ng[1], Ved Bhushan Arya[1], Pankaj Agrawal[1], Sinan Barazi[1], Cristina Bleil[1], Andrew King[1], Ayisha Al-Busaidi[1], Bassel Zebian[1], Simon Aylwin[1] & Ritika R Kapoor[1]
[1]King's College Hospital, London, United Kingdom.

Recurrent primary pituitary abscesses are exceptionally rare in paediatric populations. They pose significant diagnostic and therapeutic challenges, often requiring a multidisciplinary approach for effective management. We report the case of a 14-year-old female who presented with vomiting and a year-long history of progressively severe headaches. This was associated with polyuria, polydipsia, and a five-month history of secondary amenorrhea. Neurological examination was unremarkable with no abnormalities in visual acuity, colour vision, or visual fields. There was a past medical history of autoimmune hypothyroidism, associated with raised TPO antibodies. Magnetic resonance imaging (MRI) of the head demonstrated a suprasellar lesion impinging on the optic chiasm with restricted diffusion. Investigations revealed normal prolactin (472 mIU/L), IGF-1 (23.7 nmol/L), cortisol (415 nmol/l)and gonadotrophins with undetectable oestradiol. She underwent transsphenoidal decompression, during which caseous yellow purulent material was encountered. Histopathology revealed non-neoplastic anterior pituitary tissue with acute inflammatory exudate, consistent with a pituitary abscess, and no evidence of adenoma. Postoperatively, she received a two-week course of intravenous antibiotics and six weeks of oral antibiotics. Further investigations excluded sarcoidosis and tuberculosis. Post-operatively, she developed diabetes insipidus (serum osmolality 296 mOsm/kg, urine osmolality 93 mOsm/kg), managed with sublingual desmopressin. Hydrocortisone was initially started but stopped after confirming normal adrenal axis on a short synacthen test (SST). Menstrual cycles resumed within a month. Three months postoperatively, she developed recurrent headaches. MRI showed a cystic sellar lesion with slight stalk deviation, suggesting recurrence. A second transsphenoidal surgery six months later revealed chronic inflammation consistent with a ruptured Rathke cleft cyst. No antibiotics were given postoperatively, and cortisol response to SST was satisfactory (peak cortisol of 618 nmol/L). Seven months later, severe headaches recurred. MRI demonstrated an enlarging sellar cystic lesion, necessitating a third surgery. Histology revealed a mixed inflammatory process. The lesion was treated as a pyogenic abscess with six weeks of intravenous Ceftriaxone and Meropenem. Recovery was favourable, with no further recurrences. Postoperative endocrine evaluations were satisfactory with normal cortisol on SST. She remains on levothyroxine for autoimmune hypothyroidism and desmopressin for diabetes insipidus. A nine-month follow-up MRI showed abscess regression, and she remains asymptomatic 13 months post-surgery. This case underscores the complexities of diagnosing and managing recurrent pituitary abscesses in adolescents. The literature suggests that infectious pituitary abscess usually requires prolonged broad-spectrum intravenous antibiotics. Early recognition, prolonged intravenous antibiotics and vigilant follow-up are essential to prevent recurrences and optimise outcomes.

Germinoma of the suprasellar region: 2 cases report

Fatiha Ettalibi[1,2], Sana Rafi[1,3], Sara Ijdda[3], Ghizlane El Mghari[3] & Nawal El Ansari[3]
[1]Mohammed VI University Hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic Diseases, and Nutrition, Marrakesh, Morocco; [2]Mohammed VI University Hospital of Marrakesh, Morocco., Department of Endocrinology, Diabetes, Metabolic Diseases, and Nutrition, Marrakesh, Morocco; [1]Mohammed VI University Hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic Diseases, and Nutrition, Marrakesh, Morocco.

Introduction
Intracranial germinomas is a rare and hardly distinguishable malignancy, it presents 3% of brain tumours in children and adolescents. The clinical presentation primarily depends on the tumor's location, size, and the patient's age. This report presents a 2 cases of suprasellar germinomas.
Case presentation
Case 1: A 13-year-old patient with no significant medical history consulted at the emergency department for intracranial hypertension syndrome, ptosis, strabismus of the left eye by bilateral visual acuity decline, polyuria and polydipsia. Brain MRI revealed lesional formation in the sellar region extending suprasellarly, measuring 21×18×16 mm, in contact with the cavernous sinus and both internal carotid arteries, it infiltrates the optic chiasm and the terminal part of the right optic nerve. Additionally, there is a lesion in the mesencephalic tegmentum and pons, surrounded by edema, measuring 26×15 mm, along with a pineal gland formation measuring 14×11 mm, consistent with an extended germinoma with triple localization. Hormonal tests showed thyrotropic and corticotropic deficiencies (8 a.m. cortisol :1.54 µg/dl, FT4 :7.7 pmol/l(range: 9- 19 pmol)); FSH<0.1mIU/ml, LH: 0.1 mUI/ml. The study of tumor markers in the cerebrospinal fluid (CSF) and the biopsy of the tumor was indicative of a germinoma. **Case 2:** A 12-year-and-11-month-old patient complained of intermittent headaches for 1 year, associated with polydysptic polyuria, diplopia and recent weight loss, as well as intermittent constipation. Three months later, the clinical presentation worsened with signs of increased intracranial pressure. Brain MRI Imaging revealed a bifocal lesion measuring 53×34 mm, predominantly suprasellar, infiltrating the midbrain and extending to the pineal region. It had intimate contact with the optic chiasm, both middle cerebral arteries, and infiltrated the floor of the third ventricle, as well as the midbrain and pineal region posteriorly. Hormonal assessment revealed: FSH: 0.1 mIU/ml; LH: <0.1 mIU/ml; PRL: 100 ng/ml, FT4: 7.13 pmol/l(range: 9- 19 pmol), 8 a.m cortisol: 2,26µg/dl. The analysis of CSF supported the diagnosis of a germinoma.
Discussion/Conclusion
Suprasellar germinomas typically present with hypothalamic-pituitary dysfunction, most commonly manifesting as diabetes insipidus (DI). Endocrine disturbances appeared well before the onset of neurological symptoms and DI. Early diagnosis is essential and should be based on a rigorous evaluation of the patient's medical history, hormonal profile, laboratory results, and radiological findings. Early recognition is critical, as timely radiation and/or chemotherapy can significantly improve tumor outcomes.

Ventriculoperitoneal shunting and diabetes insipidus

Ahmed Boukhalfa[1], Sara Ijdda[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Cadi Ayad University, Mohamed VI University Hospital Center, Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Marrakesh, Morocco.

Introduction
Hydrocephalus is a complication resulting from an obstruction in the cerebrospinal fluid pathway, and is frequently observed in encephalic tumors. Symptomatic treatment consists of cerebrospinal fluid bypass, either ventriculo-peritoneal or external. Diabetes insipidus is a rarely reported complication of ventriculoperitoneal shunting. We report a clinical observation of transient diabetes insipidus complicating the placement of a ventriculoperitoneal derivation (VPD).
Clinical Case
Sixteen years-old female patient, admitted for investigation of a 15-day history of cerebellar syndrome associated with intracarnal hypertension. A cerebral CT scan revealed a lesional process in the posterior cerebral fossa responsible for tri-ventricular hydrocephalus with incipient involvement of the cerebellar tonsils. This was confirmed on brain MRI, showing a process at the expense of the cerebellar vermis. Workup noted Na: 137 mmol/land K: 3,8 mmol/l. The patient initially benefited from a Ventriculo-Peritoneal shunt, then underwent psoter-omedian surgery with macroscopic subtotal excision of a friable hemorrhagic non-encapsulated mass with removal of VPD. The histological study is in progress. After surgery and during her stay in the intensive care unit, the patient

presented a polyuropolydipsic syndrome with 6.8 l in and 6.54 l out, with clear and hypotonic urine. Urinary osmolarity was at 188 mosm/land Na at 145 mmol/l. At this stage the diagnosis of diabetes insipidus was evoked. Monitoring of the water balance was intensified, with progressive and spontaneous regression of the input-output values, with urine concentration becoming normal at day 12 post-shunt.
Discussion
Treatment of hydrocephalus saves countless patients, but CSF bypass procedures are sometimes responsible for complications of varying severity. The most common complications reported in the literature are infection, hemorrhage and shunt valve migration. Diabetes insipidus was rarely described. The pathogenic mechanism behind this complication is that when the 3rd ventricle is dilated to a large extent, the shunt valve's position at its floor impinges on the hypothalamus and pituitary stem, exerting a mass effect on ADH neurons, when compression is reversible, diabetes insipidus would be transient, another mechanism is a distortion of the V3 wall with pituitary compression. This was the case in our patient, whose diabetes insipidus spontaneously regressed following removal of the VPD.
Conclusion
Transient diabetes insipidus is a rare complication of CSF shunts for the treatment of tumor-induced hydrocephalus. This fact should be borne in mind in order to detect this manifestation and institute any necessary therapeutic measures.
Key words
hydrocephaly, ventriculoperitonel derivation, insipidus diabetes.

Clinical features of primary empty sella
Daniela Dadej[1], Katrina Skraba[2], Katarzyna Ziemnicka[1] & Marek Ruchala[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznan, Poland; [2]NHS Fife, Edinburgh, United Kingdom.

Introduction
Empty sella is a radiological finding characterized by herniation of the subarachnoid space into the sella turcica, leading to a reduction in pituitary gland thickness. It can be classified either as primary, if no preceding pituitary pathology is known or as secondary to pituitary disorders, treatment affecting the sellar region and brain injury. Primary empty sella may result from increased intracranial pressure or insufficiency of the sellar diaphragm. Factors contributing to this condition include obesity, hypertension, multiple pregnancies and female sex. The aim of this study was to characterize clinical features of primary empty sella.
Methods
We retrospectively analysed clinical data of 76 patients diagnosed with primary empty sella at the Department of Endocrinology, Metabolism and Internal Medicine in Poznan between 2011 and 2023.
Results
The majority of the cohort were women (58/76, 76%). Mean age of the diagnosis was 51 (SD 15.42) years. Partial empty sella (51/76, 67%) was more prevalent than complete empty sella (25/76, 33%). The symptoms leading to diagnosis included headaches (27/76, 35%), vertigo (6/76, 8%), irregular menstruation (4/76, 5%), recurrent syncope (3/76, 4%) and visual disturbances (2/76, 3%). Additionally, 9% (7/76) were diagnosed during evaluation of pituitary insufficiency, and 35% (27/76) were incidental findings. Obesity was present in 43% (33/76) of patients and overweight in 33% (25/76). Diabetes was diagnosed in 14% (11/76), while prediabetes was observed in 28% (21/76). A significant proportion of the cohort exhibited dyslipidaemia (43/76, 57%). Hypertension was also prevalent, affecting 53% (40/76) of patients. Hypopituitarism was diagnosed in 17% (13/76) of patients. The most common pituitary deficiency was hypogonadotropic hypogonadism, which was observed in 11 cases. Notably, two men had a history of anabolic steroid use, suggesting alternative potential cause for hypogonadism. Two or more pituitary hormone axes were affected in 77% (10/13), and among these, 90% (9/10) exhibited complete empty sella on MRI. Additionally, hyperprolactinemia was present in 5% (4/76) of patients.
Conclusions
Primary empty sella occurs predominantly in women with abnormal body weight and commonly presents with headaches. Hypertension, glucose intolerance and dyslipidaemia are frequently observed. A significant proportion of patients exhibit pituitary dysfunction, often with multiple axes involved, especially when complete empty sella is diagnosed. A substantial prevalence of metabolic comorbidities and hypopituitarism highlights the need for comprehensive evaluation and management in this patient population.

Metabolic disorders and prolactin-secreting adenomas in men
Mouna Elleuch[1], Yassmine Abdelkafi[1], Zaineb Fourati[1], Yesmine Elloumi[1], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia.

Introduction
Prolactinomas are the most common pituitary tumors. Beyond their well-documented endocrine effects, these tumors are also associated with metabolic complications that warrant careful evaluation and management.
Methods
We conducted a descriptive and analytical study involving men diagnosed with prolactin-secreting adenomas and followed at the Endocrinology and Diabetology Department of Hedi Chaker University Hospital in Sfax between January 1, 2000, and December 31, 2023. Our focus was to evaluate the metabolic effects of hyperprolactinemia in these patients.
Results
In a population of 36 men, metabolic syndrome was identified in 27.8% of cases, with overweight reported in 36.11% and obesity in 32.84% of patients. The mean waist circumference (WC) was 100.67 $\pm$ 19.21 cm. Body mass index (BMI) was positively correlated with prolactin levels, although this did not reach statistical significance in our study (rho $=$ 0.141, $P = 0.410$). However, no correlation was found between WC and prolactin levels. Regarding the metabolic effects of hyperprolactinemia, 7 patients (19.4%) were prediabetic, 3 patients (8.3%) were diabetic, and 20 patients (55.6%) presented with dyslipidemia, predominantly mixed dyslipidemia (25%). The mean total cholesterol (TC) level was 4.99 $\pm$ 1.61 mmol/l,with extremes ranging from 1.42 mmol/lto 8.8 mmol/L. Hypercholesterolemia was observed in 5 patients (13.9%). The mean LDL cholesterol level was 1.23 $\pm$ 0.49 g/l,with extremes ranging from 0.5 g/lto 2.49 g/l,and elevated LDL cholesterol was reported in 5 patients. The mean HDL cholesterol level was 1 $\pm$ 0.29 mmol/l,with extremes ranging from 0.41 mmol/lto 2.04 mmol/l,while low HDL cholesterol levels were observed in 2 patients. The mean triglyceride (TG) level was 1.90 $\pm$ 1.06 mmol/l,with extremes ranging from 0.5 mmol/lto 5.04 mmol/L. Hypertriglyceridemia was noted in 4 patients (11.1%). Our findings revealed positive correlations between prolactin levels and TC (rho $=$ 0.186, $P =$ 0.277), LDL cholesterol (rho $=$ 0.258, $P = 0.134$), and triglycerides (rho $=$ 0.022, $P = 0.901$). However, no relationship was identified between fasting blood glucose and prolactin levels in our cohort.
Conclusion
Metabolic syndrome represents a significant complication of prolactin-secreting adenomas in men. Its presence highlights the need for comprehensive evaluation and targeted management strategies to mitigate its impact on long-term health outcomes. Addressing these metabolic disturbances is essential for optimizing the overall care of patients with prolactinomas.

Pituitary macroadenoma in the menopause may be a prolactinoma?
Susana Mallea-Gil[1], Laura Boero[2], Carolina Ballarino[1], Karina Danilowicz[2], Mirtha Guitelman[3], Monica Loto[4], Analia Pignatta[5], Soledad Sosa[2] & Amelia Rogozinski[6]
[1]Hospital Militar Central, Endocrinology, Buenos Aires, Argentina; [2]Hospital de Clínicas J de San Martin, Endocrinology, Buenos Aires, Argentina; [3]Hospital Durand, Endocrinology, Buenos Aires, Argentina; [4]Hospital Britanico, Endocrinology, Buenos Aires, Argentina; [5]Hospital Interzonal San Juan Bautista, Endocrinology, Catamarca, Argentina; [6]Hospital Ramos Mejia, Endocrinology, Buenos Aires, Argentina.

In women, prolactinomas are usually diagnosed between 20 and 40 years old, they are not frequently detected in postmenopausal women because they do not usually present symptoms of hyperprolactinemia as the ovarian function has stopped. There are scarce published data on their presentation and prognosis. The prevalent symptoms in this age are tumor mass effects. The exact incidence of prolactinomas in postmenopausal women is unknown.
Objective
Assess the clinical symptoms, biochemical and imaging findings at presentation, follow-up and the outcome in a cohort of postmenopausal women with prolactinomas.
Material and Methods
Retrospective, multicenter study in Argentina between 2014-2024. Nine patients with prolactinomas diagnosed in menopause were evaluated. The following

patients' data were recorded: age at last menstruation, age at prolactinoma diagnosis, adenoma size (mm), visual field, treatments performed, and biochemical determinations. For the statistical analysis, Infostat software was used. The results are expressed according to data distribution as median (Q1-Q3).
Results
The median age at diagnosis was 62 (60-68). The median age of the last menstruation was 47 (35-48); in 4 cases was reported before 40, 56% of patients had pregnancies before prolactinoma diagnosis. The most commonly symptoms at diagnosis were: headaches (2/9), and visual field defects (VFD) (5/9): 2 patients had bilateral hemianopsia, 1 had unilateral hemianopsia and 2 bilateral quadrantopsia; galactorrhea was present in 33%; 5/9 were incidental findings. Median serum prolactin was 1325 ng/ml (1000-2695), all patients had secondary hypogonadism (low levels LH, FSH and estradiol), 44% of the patients had other pituitary axes affected, the most frequent were thyroid and adrenal. Macroadenomas and cavernous sinus invasion macroadenomas were diagnosed in 56% and 44%, respectively. All the patients were treated with cabergoline, with doses between 1-4 mg/week, median treatment period was 60 (24-63) months. In the follow-up, 8/9 normalized prolactin levels, 7/9 women had reduction of the tumor size in more than 50 %, and tumor disappeared in the other 2. Most of these women (75%) normalized VFD.
Conclusions
In our series of patients with prolactinomas diagnosed in the postmenopausal period, the incidental finding at diagnosis of prolactinoma was more frequent compared to other publications. Almost half of the patients had the last menses in their fertile age, we can hypothesize that prolactinomas were present in that period but the diagnosis was made after menopause. All women treated with cabergoline had an excellent response in size reduction of adenomas, improved VFD and normalize prolactin levels.

A hazard of transitional endocrine care

Jack Lego[1] & Margaret Zacharin[1,2]
[1]Royal Children's Hospital, Department of Endocrinology and Diabetes, Melbourne, Australia; [2]Murdoch Children's Research Institute, Melbourne, Australia.

A 25 year-old woman with childhood onset panhypopituitarism after surgery, cranial radiation and chemotherapy for a midline germinoma presented to a rural hospital in a low-middle income country with acute confusion and vomiting, which occurred during attendance at a party. Despite administration of appropriate parenteral stress dosing of glucocorticoids by her friend, improvement did not occur. Assessment suggested a presumptive diagnosis of gastroenteritis. She was initially managed with crystalloid intravenous fluid resuscitation, without recognition of her diabetes insipidus (DI). Serum sodium was reported as 114 mmol/L. Contact was made with an endocrinologist who advised cessation of intravenous fluids. With fluid restriction, hyponatraemia, confusion and vomiting resolved. Throughout her presentation she remained afebrile, had no diarrhoea, nor any other infective symptoms and recovered rapidly. On return home she subsequently stated that she thought her "drink may have been spiked". Although the evidence is presumptive that ingestion of 3,4-methylenedioxymethamphetamine (MDMA) is likely to have been involved, the case is important in that it demonstrates potential hazards that need to be navigated when negotiating transition to adult care for young adults who have complex disorders, and the need for awareness of drug and alcohol interactions that may have potentially catastrophic outcomes if not recognized. There have been multiple reports of hyponatraemia in MDMA users since it was first described in 1993, predominantly affecting females. To our knowledge, there are no reported cases of hyponatraemia following MDMA use in patients with DI. The mechanism for hyponatraemia following MDMA ingestion is thought to be multifactorial with proposed mechanisms including syndrome of inappropriate anti-diuretic hormone release; MDMA-induced polydipsia and dry mouth (with subsequent thirst and ingestion of hypotonic fluid); and recommendations to remain well-hydrated after MDMA use to counter-act the risk of dehydration from increased diaphoresis and hyperthermia all postulated as a possible contributors. In this case, the patient's DI excludes SIADH as an aetiology for her hyponatraemia and parenteral glucocorticoid administration was adequate. In conclusion, the case demonstrates an absolute need for meticulous transitional care and adequate advice for young adults with complex health issues for clinicians, both paediatric and adult.

Validity of adult height prediction methods (bayley pinnaue charts and bonexpert) in indian children with idiopathic short stature

Vishakha Varshney[1], Rajni Sharma[1], Priyanka Gupta[1], Vandana Jain[1], Manisha Jana[2] & Devasenathipathy Kandasamy[2]
[1]All India Institute of Medical Sciences, Pediatrics, New Delhi, India; [2]All India Institute of Medical Sciences, Radiology, New Delhi, India.

Background
Adult height can be predicted using Bayley-Pinneau (BP) method and BoneXpert software. However, data comparing validity of these methods in Indian children is scarce.
Aim
To assess the accuracy of predicted adult height (PAH) in Indian children with idiopathic short stature (ISS) using BP method and BoneXpert software.
Methods
Children diagnosed with ISS and attending the Pediatrics OPD were identified from clinical records and contacted. Children with ISS and had achieved final adult height (FH) [closure of epiphyses/Bone Age (BA) $>$ 16 years (male)/$>$14 years (females)] were included, and those with non-availability of BA radiographs and birth weight $<$2kg were excluded. BA was calculated using GP atlas and BoneXpert software, and PAH was calculated using BP method and BoneXpert software. These PAHs were then compared with their actual FH to assess the accuracy of these prediction models.
Results
A total of 27 cases (12 males) (mean age: 13.7 $\pm$ 2.1 years in boys and 11.8 $\pm$ 2.2 years in girls) were enrolled for which BA was calculated using GP atlas and predicted adult height (PAH) using BP method. However, BoneXpert could be used for only 25 cases (11 males) as digital x rays were not available for 2 children. BA determination showed good correlation between GP method and BoneXpert (r = 0.85; P $<$0.001). BP method accurately predicted FH in 8 (6 girls) out of 27 cases with an accuracy of 29.6%. BoneXpert accurately predicted FH in 15 (8 females) out of 25 cases with accuracy of 60%. BoneXpert was more accurate than BP method in predicting adult height (P value = 0.027).
Conclusion
BoneXpert was more accurate than BP method in predicting adult height. Males had significantly greater difference in PAH using BP method compared to females.

Pre-treatment differentiation between non-functioning pituitary adenomas and prolactinomas based on serum prolactin levels

Loren van der Hoeven[1,2], Julia Berg[2], Miou Koopman[3], Jacquelien Hillebrand[4], Madeleine Drent[1,5], Eleonora Aronica[1,6], Jantien Hoogmoed[1,7], Alberto Pereira[1,2] & Dirk Jan Stenvers[1,2,5]
[1]Pituitary Center Amsterdam UMC, Amsterdam, Netherlands; [2]Amsterdam UMC, University of Amsterdam, Department of Endocrinology and Metabolism, Amsterdam Gastroenterology Endocrinology and Metabolism (AGEM), Amsterdam, Netherlands; [3]Amsterdam UMC, University of Amsterdam, Department of Radiology and Nuclear Medicine, Amsterdam, Netherlands; [4]Amsterdam UMC, University of Amsterdam, Department of Laboratory Medicine, Endocrine Laboratory, Amsterdam Gastroenterology Endocrinology and Metabolism (AGEM), Amsterdam, Netherlands; [5]Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Endocrinology and Metabolism, Amsterdam Gastroenterology Endocrinology and Metabolism (AGEM), Amsterdam, Netherlands; [6]Amsterdam UMC, University of Amsterdam, Department of (Neuro)Pathology, Amsterdam, Netherlands; [7]Amsterdam UMC, University of Amsterdam, Department of Neurosurgery, Amsterdam, Netherlands.

Introduction
Non-functioning pituitary adenomas (NFPAs) can present with hyperprolactinemia, presumably due to the pituitary stalk effect. This makes it challenging to differentiate between NFPAs and prolactinomas. In turn, this negatively affects

the shared decision making process when choosing between primary dopaminergic treatment or transsphenoidal surgery. This shared decision making has increasing importance now that transsphenoidal surgery by an experienced surgeon is considered a valuable first line of treatment for prolactinomas. In the current position statement, elevated serum prolactin (PRL) levels above 250 µg/l(5.3 [IU]/L), around 11 times the upper limit of normal (ULN, set at 22 µg/l(0.47 [IU]/L)), are considered indicative of prolactinomas, whereas PRL levels of up to 150 µg/l(3.2 [IU]/l)in patients with NFPAs are attributed to the stalk effect.

Aim

To determine pretreatment cut-off values of PRL with the aim to differentiate between a prolactinoma and NFPA in patients with a radiological proven pituitary adenoma (PA) and elevated PRL.

Patients and Methods

Retrospective cohort study of patients who underwent transsphenoidal surgery between 2011 and July 2023. Inclusion criteria were 1) a histopathologically confirmed diagnosis of either a NFPA or a prolactinoma and 2) pretreatment elevated PRL levels and available pretreatment MRI. Peak PRL levels were converted to x times the local ULN to avoid standardisation differences between the used immunoassays. Diagnostic performance of peak PRL was analyzed using receiver-operating characteristics curves to calculate the area under the curve, and sensitivity and specificity. The reference standard was WHO 2017/2022 histopathological diagnosis of a (densely/sparsely granulated) lactotroph adenoma.

Pre-liminary results

Data of 80 patients (55 NFPAs and 25 prolactinomas) were analyzed. Median peak PRL levels in patients with a NFPA was 1.8 ULN (IQR 1.1, minimum 1.0, maximum 7.6). Median PRL levels in prolactinomas was 34.2 ULN (IQR 351.4, minimum 1.2, maximum 1140.0). Based on our pre-liminary results, not corrected for tumor volume, our suggested cut-off value of PRL to distinct between prolactinomas and NFPA with hyperprolactinemia ranges between 3.1 and 3.3 ULN (sensitivity range 88-92%, specificity range 80-84%).

Conclusion

Based on these preliminary results, a PRL level cut-off value of 3.1-3.3 ULN is suggested to distinct prolactinomas from NFPAs with hyperprolactinemia. This translates, based on a reference value of 22 µg/l(0.47 [IU]/L), to 68-73 µg/l(1.4-1.5 [IU]/L), substantially lower than the cutoff in the position statement. Additional analyses to evaluate the impact of tumor dimensions are ongoing.

JOINT2703

Radiological evaluation of central nervous system in children with gonadotropin-dependent precocious puberty

Monika Seifert[1], Agnieszka Zubkiewicz-Kucharska[1], Beata Wikiera[1] & Robert Śmigiel[1]

[1]Medical University in Wroclaw, USK in Wrocław, Department of Pediatrics, Endocrinology, Diabetology and Metabolic Diseases, Wrocław, Poland.

Central precocious puberty (CPP) is caused by activation of hypothalamic-pituitary-ovarian axis. This leads to the appearance of secondary sexual characteristics in girls under 8 years of age, and in boys under 9 years of age. CPP must be determined on the basis of laboratory and imaging tests, and clinical examination.

The aim

of the study was to analyze the radiological changes of central nervous system (CNS) in MRI in CPP children treated with gonadotropin analogs (Triptorelin/Dipherelin) (aGnRH) in one endocrinology center.

The study group

consisted of 116 children with CPP: 96 girls (82.76%) and 20 boys (17.24%). Mean age of children was 6.77 ± 2.44 years. Significant changes in MRI were considered: pituitary enlargement, optic nerve glioma, hamartoma, pituitary malformation, hypoplasia of the corpus callosum, hydrocephalus, epileptic encephalopathy.

Results

CNS pathology was significantly more prevalent in boys (8/20; 40%) than girls (20/96, 20,8%). The most often diagnosed significantly important lesions of CNS were: enlargement of the pituitary gland/microadenoma (13), hydrocephalus (4), optic nerve glioma (3), hypothalamic hamartoma (3), pituitary deformity (2), gangliocytoma (1), corpus callosum hypoplasia (1), epileptic encephalopathy (1). Children with significant changes in MRI of the head were younger (girls 5.7 ± 2.5 and boys 4.86 ± 3.13) compared to children with a normal radiological image (girls 7.14 ± 2.24 and boys 7.41 ± 1.6). Clinically insignificant lesions included: pineal cyst (5), Rathke's pouch cyst (1), intermediate layer cyst (2), pituitary cyst (1), asymmetry of the sella turcica (1), mild downward displacement of cerebellar tonsils through the foramen magnum (1), and asymmetry of the left lateral ventricle (1). CNS significant pathology coexisted with the following diseases in our group: congenital adrenal hyperplasia (CAH, 2 boys), neurofibromatosis type I, (NF-1, 2 boys), epilepsy (1 girl), Silver-Russell syndrome during the rhGH therapy (1 girl), cerebral palsy (CP, 1 girl), McCune-Albright syndrome, (1 girl), panhypopituitarism (1 girl).

Conclusions

1. The frequency of significant abnormalities in the MRI of the head in our group of children with CPP is 24.1%.
2. Children with significant changes in MRI were younger at the time of diagnosis compared to children with a normal radiological image.
3. CPP is much more often diagnosed in girls in comparison to boys.

Analysis of pituitary tumors in a single center in slovakia

Barbora Bačkorová[1], Marek Felšőci[1], Jana Figurová[1], Hedviga Wagnerová[1] & Ivica Lazurová[1]

[1]Louis Pasteur University Hospital, 1st Department of Internal Medicine, Košice, Slovakia.

Background

Pituitary adenomas are the most common pituitary lesions. The prevalence of incidental pituitary adenomas ranges from 10% to 22%. In contrast, the prevalence of undiagnosed macroadenomas is very low, primarily due to their mass effects on nearby structures or their hormonal activity. Other, less common lesions are pituitary carcinoma, craniopharyngioma or Rathke's cleft cyst.

The objective

of this retrospective observational study was to evaluate the prevalence of pituitary tumors, as well as their demographic characteristics, treatment approaches, and clinical outcomes.

Methods and Results

In a single centre of the University Hospital, altogether 196 patients were diagnosed with pituitary tumors based on their laboratory and imaging results between 2009 and 2024 (106 women, 90 men, age 22–92 years). Of these, 125 patients were diagnosed with macroadenoma (63.8% vs. 68.7% in literature), 41 with microadenoma (20.9% vs. 10% in literature), 4 (2%) with picoadenoma, 5 (2.6%) craniopharyngiomas, 17 (8.6% vs. 13.1% in literature) Rathke's cleft cysts, and 4 (2%) other lesions, respectively. Surgical resection was performed in 103 patients (52.6%), and 11 (10.7%) of them required surgical revision. Additionally, 38 patients (19.4%) underwent radiation therapy. Histological analysis of resected macroadenomas revealed the following subtypes: 32 (38.6% vs. 22.8% in literature) nonfunctioning adenomas, 21 (25.3% vs. 21.8% in literature) gonadotroph adenomas, 18 (21.7% vs. 9.6% in literature) somatotroph adenomas, 5 (6% vs. 28.3% in literature) prolactinomas, 4 (4.8% vs. 9.4% in literature) corticotroph adenomas, and 3 patients (3.6%) with somatomammotroph adenomas. Based on hormonal secretion, 83 (66.4%) were non-functioning adenomas, growth hormone production was detected in 23 (18.4%), PRL secretion in 16 (12.8%), and ACTH secretion was demonstrated in 2 (1.6%) patients. One patient (0.8%) was diagnosed with concurrent PRL and GH secretion. Among microadenomas, 22 (53.6%) were non-functioning, 12 (29.2%) produced PRL, 5 (12.2%) GH, and 2 (4.8%) had ACTH, respectively. Overall, hypopituitarism developed in 77 patients (39.3% vs. 37–85% in literature). Gonadotropin deficiency was found in 26 (13.3% vs. 36–96% in literature), TSH deficiency in 55 (28.1% vs. 8–81% in literature), GH deficiency in 7 (5.6% vs. 61–100% in literature), and diabetes insipidus in 18 patients (9.2%). Hydrocortisone supplementation was required in 66 patients (33.7% vs. 17–62% in literature).

Conclusion

Among pituitary tumours, the most common are nonfunctioning adenomas. The prevalence of hypopituitarism was relatively high in our patients. Early diagnosis improves the clinical outcome of patients and may prevent irreversible pituitary destruction.

Ectopic cushing's syndrome due to a pulmonary NET: diagnostic challenges and the need for a multidisciplinary approach

Ruben Carrasco[1], Carla Santivañez[1], Alba Juanes[2], Carmen Marrón[3], Mariña Veras[4], Elisa Martínez[5], Victor Godigna[5], M. Soledad Librizzi[1] & María Calatayud[1]
[1]Hospital 12 de Octubre, Endocrinology and Nutrition Service, Madrid, Spain; [2]Hospital 12 de Octubre, Psychiatric Service, Madrid, Spain; [3]Hospital 12 de Octubre, Thoracic Surgery Service, Madrid, Spain; [4]Hospital 12 de Octubre, Anatomic Pathology Service, Madrid, Spain; [5]Hospital 12 de Octubre, Nuclear Medicine Service, Madrid, Spain.

Introduction
Cushing's syndrome (CS) is a rare disease, with 10–15% of cases caused by ectopic ACTH secretion. Clinical presentation ranges from mild to severe hypercortisolism with high mortality. The etiology includes well-differentiated neuroendocrine tumors (NETs) or undifferentiated tumors, complicating diagnosis and management. A multidisciplinary approach and advanced diagnostic techniques are essential. This case highlights the complexity of early diagnosis, comprehensive management, global support, and prolonged evaluation.
Objective
To describe a case of ACTH-dependent ectopic CS, emphasizing the integration of diagnostic methods and the importance of a multidisciplinary approach.
Case Report
A 34 year-old male with a history of anxiety-depressive disorder and progressive obesity was admitted for Fournier's gangrene requiring secondary intention wound closure. He developed severe hypokalemia (2.5mEq/l)resistant to treatment, new-onset Diabetes Mellitus (HbA1c 8.2%) requiring insulin therapy, and fluctuating psychiatric symptoms, including mutism and treatment refusal. PE revealed moon facies, dorsal fat pad, central obesity, violaceous abdominal striae, and significant proximal muscle weakness with generalized sarcopenia. CS was suspected and confirmed by endocrinological evaluation: - 24-hour urinary free cortisol: 3672.0µg/24h (normal 13-75µg/24h). - Serum cortisol: 22.80µg/dl (normal 5-25µg/dl). - Plasma ACTH: 89.95pg/ml (normal 10-50pg/ml). - Late-night salivary cortisol: 3.170µg/dl (normal $<$0.208µg/dl). Given the hypercortisolism severity, ectopic ACTH secretion was suspected.
Clinical Course
The patient was transferred to the ICU for hypokalemia management and psychiatric stabilization. Treatment with metyrapone and ketoconazole was initiated, rapidly escalating doses with a block-and-replace strategy using hydrocortisone. Spironolactone was added for hypokalemia and hypertension control. Thromboprophylaxis with heparin and antibiotic prophylaxis with TMP-SMX were implemented. Thoracoabdominopelvic CT revealed a 10$\times$15mm pulmonary nodule in the left lower lobe. 68Ga-DOTATOC PET/CT confirmed a high-uptake pulmonary nodule (SUVmax21.9), suggesting SSTR overexpression without metastases. A multidisciplinary team recommended surgery after hypercortisolism control. Nutritional support with high-protein supplements and rehabilitation were initiated. Following hypercortisolism control and clinical stabilization, left lower lobectomy was performed. Pathology confirmed a typical G1 pulmonary NET (WHO2021), 2cm in size, with clear surgical margins (Ki-67 1.7%). A supradiaphragmatic lymph node revealed metastatic typical carcinoid NET G1 with extracapsular extension (Ki-67 2.1%), pT1bN2. Immunohistochemistry was positive for TTF1, INSM1, chromogranin, synaptophysin, ACTH, and SSTR. Surgery allowed cessation of hypercortisolism treatment, where psychiatric symptoms corrected and Fournier's gangrene healed.
Conclusions
A multidisciplinary approach is essential for diagnosing and treating NET-associated CS. Advanced techniques such as 68Ga-DOTATOC PET/CT are crucial for early diagnosis. Management of complications are fundamental to successful treatment and patient recovery.

A rare etiology of autoimmune hypophysitis

Yesmine Elloumi[1], Khouloud Boujelben[1], Dhoha Ben Salah[1], Hamdi Frikha[1], Ameni Ben Abdallah[1], Hadjkacem Faten[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1], Mouna Elleuch[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia.

Background
Chemotherapy is widely used to treat various cancers, but it can also result in a range of side effects, some of which are rare and underrecognized. Autoimmune hypophysitis, an inflammation of the pituitary gland, is an uncommon complication.
Case Report
A 47-year-old woman with a history of hypertension and breast cancer, treated with total mastectomy, adjuvant radiotherapy, and chemotherapy (cyclophosphamide, paclitaxel, and epirubicin), presented with palpitations. ECG showed a sinus tachycardia. A TSH test was ordered, revealing a low value of 0.06 µIU/ml, and she was referred to our endocrinology department. On examination, the patient was in a state of eucortisism, with a blood pressure of 14/10 cmHg, in an euthyroid state, without galactorrhea or exophthalmos. She has been menopausal for one year. Further tests showed a controlled TSH level of 1 µIU/ml, FT4 at 10 pmol/l(normal range: 7-16), morning cortisol at 44.5 µg/l,FSH at 72.1 mUI/ml, LH at 47.8 mUI/ml, and prolactin at 5.61 ng/ml. A Synacthen test confirmed adrenal insufficiency, and ACTH was measured at 13.5 pg/ml (normal range: 7-63), suggesting a central origin. The patient was started on hydrocortisone replacement. An MRI of the hypothalamo-pituitary region revealed a bulging aspect of the pituitary gland, with no focal lesions detectable, and a thin pituitary stalk, consistent with autoimmune hypophysitis.
Conclusion
This case report highlights a rare instance of chemotherapy-induced autoimmune hypophysitis, emphasizing the importance of early recognition and timely intervention.

Calcitonin-secreting neoplasm of the lung: a case report

Gökhan Rıza Baykal[1], Şefika Burçak Polat[2], Mehmet Gümüş[3], Nilüfer Odak Kandemir[4], Bülent Yalçın[3], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [3]Ankara Yıldırım Beyazıt University, Faculty of Medicine, Ankara Bilkent City Hospital, Department of Radiology, Ankara, Türkiye; [4]Ankara Bilkent City Hospital, Department of Pathology, Ankara, Türkiye; [5]Ankara Yıldırım Beyazıt University, Faculty of Medicine, Ankara Bilkent City Hospital, Department of Medical Oncology, Ankara, Türkiye.

Background
Calcitonin (CTN)-secreting neuroendocrine neoplasms of the lung are very rare tumors. Differentiating between medullary thyroid cancer and an ectopic source of calcitonin secretion is challenging. Abnormal calcitonin concentrations have been linked to extra-thyroidal sources in neuroendocrine neoplasms located in the pancreas, parathyroid glands, thymus, esophagus, lung, small intestine, adrenal glands, and bladder.
Case
A 54-year-old male patient presented with weight loss, nausea, vomiting, and back pain. He had no other disease and was not on any regular medications. Calcitonin was 1011 ng/l,and CEA was 3.8 ng/ml. Thyroid USG shows an iso-hypoechoic nodule measuring 21x23x24 mm in the right inferior posterior region, containing cystic degeneration areas and macrocalcifications. The nodule's fine needle aspiration cytology showed atypia of undetermined significance, and the CTN washout was negative. During chest and abdominal imaging, a mass measuring about 45x40 mm was found in the lower lobe of the right lung, and a 56x63 mm mass lesion that showed uneven enhancement was found in the right adrenal gland. Plasma metanephrine levels were normal. We referred him for an 18fluoro-deoxyglucose PET (18FDG-PET), which revealed normal metabolic activity throughout the thyroid. There was high uptake (SUVmax 14.39) within the 4.5 cm mass lesion located in the posterior lower lobe of the right lung and the 6.5 cm mass lesion in the right adrenal gland (SUVmax 10.77). A biopsy diagnosed the patient's lung mass as pulmonary neuroendocrine carcinoma. Malignant cells were positive for CD56, synaptophysin and calcitonin. Staining for chromogranin A and Napsin A was negative. The Ki-67 proliferation index was high at 70%. The medical oncology department initiated systemic chemotherapy. Follow-up imaging after chemotherapy showed progressive disease.
Conclusion
This case highlighted the complexity of the differential diagnosis of hypercalcitoninemia, more particularly the difficulty of distinguishing between medullary cancer and a tumor with ectopic calcitonin release. The different diagnoses are important since treatment and prognosis are different. The approach to hypercalcitoninemia requires a multidisciplinary one. It is important to perform a complete clinical evaluation of these patients so that ectopic calcitonin-secreting tumors are not overlooked.

JOINT4044

FIPA-AIP positive pituitary gigantism: post-surgical remission

Mirtha Guitelman[1], Carmen Riu[1], Julieta Tkatch[1], Adrian Daly[2], Veronica Fernandez Mentaberry[1], Martin Guevara[3] & Adriana Oneto[4]
[1]Hospital Carlos G Durand, Endocrinology Division, Buenos Aires, Argentina; [2]Centre Hospitalier Universitaire de Liège, Liege, Belgium; [3]Hospital Universitario CEMIC, Buenos Aires, Argentina; [4]TCBA centro de diagnóstico, Buenos Aires, Argentina.

Introduction
Familial isolated pituitary adenomas (FIPA) are one of the most important inherited settings for pituitary adenomas and the most frequent genetic cause is a germline mutation in the aryl hydrocarbon receptor-interacting protein (AIP) gene. AIP mutations lead to young-onset macroadenomas that are di cult to treat. Most are growth hormone secreting tumors.
Clinical case
A 14-year-old male patient complained for insulin resistance and physiognomic changes throughout the last 2 years. His mother was diagnosed with acromegaly at the age of 16, cured after 2 surgeries and a short period of somatostatin analogues. On physical examination his height was 180,5 cm (+2.51 SDS), weight of 78 kg (+2,18 SDS), and Tanner stage IV. Target height was 172,25 cm -0.08 SDS (Δ H/TH: +2,6 SDS). The shoe size 42, and had acanthosis nigricans on the neck. Hormonal assessment revealed a basal GH of 21.5 ng/ml, a nadir post-glucose GH of 18.5 ng/ml, and IGF-1 of 556 ng/ml (Range age/sex: 211-512) (+ 3.97 SDS). Prolactin and testosterone levels were within the normal range, as well as the evaluation of the adrenal and thyroid axes. MRI showed a macroadenoma with mild suprasellar extension, and sphenoid sinus invasion, with no extension to cavernous sinuses. The patient was operated on by transsphenoidal approach without complications; the histopathology reported a sparsely granulated somatotropinoma, with Ki 67 of 10%. The AIP gene analysis performed using the MLPA technique, resulted positive for both the patient and his mother (Heterozygous missense pathogenic variant c.136G>T (p.Glu46*) Three months after surgery, IGF1 decreased to +0.31 SDS, with a random GH of 0.8 ng/ml; insulin levels normalized and the MRI did not show images of tumor remnant. Two years after surgery, the patient remained in remission, with a post-glucose GH nadir of 1 ng/ml and IGF1 < 1 UNL, and normal gonadal axis (IGF1: 399 ng/ml (+ 1,42 SDS) (57-426), Testosterone: 5 ng/ml). During follow-up there was a significant slowdown in growth velocity.
Discussion
This is a 16-year-old patient with familial acro-gigantism, AIP positive, operated on for a macroadenoma with histopathological markers of poor prognosis with a high chance of recurrence and aggressiveness. Two years after surgery, he presents biochemical remission markers, without tumor remnant and asymptomatic. Strict clinical, biochemical and imaging monitoring is necessary given the poor prognostic tumor markers and positive genetics.

JOINT3543

Transient arterial hypertension developed during therapy with triptorelin in a girl with central precocious puberty

Magdalena Banaszak-Ziemska[1] & Marek Niedziela[1]
[1]Institute of Pediatrics Karol Jonscher's Clinical Hospital Poznan University of Medical Sciences, Department of Pediatric Endocrinology and Rheumatology, Poznań, Poland.

Introduction
Gonadotropin-releasing hormone analog (aGnRH) is used for the treatment of central precocious puberty (CPP) in childhood and has a good safety profile, with minimal side effects like menopause-like symptoms or local changes at the injection side. In the literature, there are a couple of case reports about the development of transient hypertension during aGnRH treatment.
Case report
We present a case of a girl with a fast progression of CPP with transient arterial hypertension developed during therapy with aGnRH. At the age of 8 years and 9 months, she was diagnosed in the Paediatric Endocrinology Department due to breast and pubic hair development before the age of 8 years. After LH-RH domination of LH was found, fast progression of breast development and advancement of bone age was observed, and bone age was 10 years. Her height was 135,8 cm (50-75pc), her weight was 32,5 kg (50-75pc), and her target height was 169 cm (50-75pc). Therapy with Diphereline SR was initiated. At the age of 8 years and 11 months, she started complaining of recurrent headaches and nose bleeding; BP was 135/85 mmHg at the beginning, with the progression to 155/104 mmHg six months later. In the abdomen ultrasound, double right kidney vessels were found. Hormonal profile with renin, aldosterone, and metoksycatecholamin were in the normal range. She was consulted with an ophthalmologist, and an eye fundus examination revealed no abnormalities. Heart image in echocardiography was proper, but LVMI was elevated at 39,46 (> 95pc for sex and age). In ambulatory blood pressure monitoring (ABPM), hypertension was diagnosed, and treatment with amlodipine was recommended; an initial dose was 2,5mg once a day. Although the treatment, BP was still above the normal range in home monitoring, and in ABPM, ACEI was added to the therapy. At the age of 10 years, due to the development of symptomatic hypertension with heart complications and due to mitigation of CPP progression, treatment with aGnRH was finished. After a month in ABPM, blood pressure was much below 50pc, and amlodipine was discontinued. After the following two months, due to BP values much below 50pc, ACEI was also discontinued. BP remains in the normal range.
Conclusions
Despite the good safety profile of aGnRH, hypertension could be a significant problem during therapy. Based on our case and other earlier reports, regular evaluation of BP should be a part of patient with CPP monitoring.

JOINT4043

Assessment of comorbidity resolution after long-term acromegaly remission

Francisca Leitão[1], Ana Quítalo[1], Daniel Duarte[1], Marta Almeida[1], Ana Gonçalves Ferreira[1], Henrique Vara Luiz[1] & Maria Carlos Cordeiro[1]
[1]Hospital Garcia de Orta, Almada, Portugal.

Introduction
Acromegaly is a rare endocrine disorder associated with a wide range of comorbidities, including cardiovascular disease, metabolic disorders, and musculoskeletal complications. Surgical resection of the pituitary tumor is the primary treatment, and achieving long-term remission can significantly improve clinical outcomes. However, the impact of remission on pre-existing comorbidities and the development of new complications after surgery is variable.
Objective
This study aims to evaluate the resolution of comorbidities after achieving long-term acromegaly remission following surgical intervention.
Methods
Retrospective study of all surgically treated acromegaly patients followed at our center from 1992 to 2024. GH and IGF-1 levels were assessed to evaluate acromegaly remission. Resolution of each comorbidity was defined if it was controlled without requiring pharmacological treatment.
Results
Fifty-two patients with acromegaly were included, with 28 (54%) females. The mean age at diagnosis was 46 years, with a mean symptom duration of 6 years. The median follow-up was 7 years. Comorbidities were reported in most patients, including hypertension in 25 (48%), arthropathy in 16 (31%), type 2 diabetes (T2D) in 12 (23%), obstructive sleep apnea in 5 (10%) and colon polyps in 8 (15%). All patients underwent surgery and one-year postoperative biochemical remission was found in 21% of patients (8/39). Among patients who achieved remission, pre-surgery comorbidities included dyslipidemia in 38% (3/8), hypertension in 50% (4/8), T2D in 25% (2/8), and obstructive sleep apnea in 25% (2/8). Currently, with a mean follow-up of 10 years, resolution of comorbidities was observed in 33% (1/3) for dyslipidemia, 100% (2/2) for T2D, and 100% (2/2) for obstructive sleep apnea. No new comorbidities developed during follow-up.
Conclusions
Treating patients with acromegaly may improve associated comorbidities such as T2D, obstructive sleep apnea and dyslipidemia. Nevertheless, only a limited number of comorbidities can show full reversibility, emphasizing the need for early diagnosis and intervention to prevent long-term complications.

JOINT2449

Usefulness of serial prolactin measurement to confirm the presence of hyperprolactinemia

Raúl Rodríguez Juárez[1], Elena Martínez Silla[1], Laura Cánovas Noguera[1], Juan Luis Delgado Montoya[1], Nuria Birruezo Hernández[1], Yael Giner

Esteban[1], Maria Dolores Aviles Perez[1], Torralbo Martín[1] & Pablo J López-Ibarra Lozano[1]
[1]Hospital Universitario Clínico San Cecilio, Granada, Spain.

Introduction
Hyperprolactinemia is a frequent cause of referral to endocrinology outpatient clinics, which is due to many causes (physiological, pharmacological, pathological). Once some have been excluded, many studies recommend performing a serial prolactin measurement to rule out stress hyperprolactinemia, although it isn't standardised. Objective: to evaluate the usefulness of serial prolactin measurement to confirm hyperprolactinemia diagnosis.
Materials and Methods
Descriptive study of 60 patients who underwent serial prolactin measurements between the years 2023-24 in follow-up in our clinics. Demographic (sex, age) and analytical (basal prolactin, at 20 and 40 minutes) variables were collected. Regarding the measurement, a peripheral intravenous line was inserted and a baseline, at 20 and at 40 minutes value was taken. It was established that prolactin was elevated above 20 (men) or 25 (women). The statistical analysis was performed with the IBM SPSS v.25 programme (Statistical significance $P < 0.05$).
Results
60 patients were analysed, 80% women with a mean age of 31.1 $\pm$ 14.7 years. 66.7% and 70% showed normal prolactin values at 20 and 40 minutes, respectively. Basal and 20-minute prolactin and basal and 40-minute prolactin means difference were 4 $\pm$ 7.1 and 6.5 $\pm$ 10.8, with a statistical significance of 0.01 in both.
Conclusions
In most patients, prolactin levels become normal after 20 and 40 minutes of sampling, after removing other confounding factors that may lead to stress hyperprolactinemia. A statistically significant difference is also observed between baseline, at 20 and at 40 minutes values. This demonstrates the usefulness of the measurement to rule out stress hyperprolactinemia, as well as to avoid redundant complementary tests and avoid unnecessary worries for the patient.

Prevalence of sexual dysfunction in patients with pituitary disease: insights from the international DREAMS survey study

Svenja Leibnitz[1,2], Andi Nikaj[1,2], Cihan Atila[1,2] & Mirjam Christ-Crain[1,2]
[1]University Hospital of Basel, Department of Endocrinology, Basel, Switzerland; [2]University Hospital of Basel, Department of Clinical Research, Basel, Switzerland.

Background
Sexual well-being is a complex process that involves both mental and physical aspects, influencing quality of life. Pituitary dysfunction is often associated with sexual dysfunction due to its critical role in regulating hormones involved in sexual health. In this patient group, sexual dysfunction may include impacts on sexual satisfaction, intimacy, function and fertility, significantly affecting quality of life. Despite its importance, there are limited systematic evaluations of sexual dysfunction across different subtypes of pituitary dysfunction. Therefore, this survey aimed to assess the prevalence and severity of sexual dysfunction in patients with pituitary disorders.
Methods
This cross-sectional, web-based, anonymous survey was designed by endocrinologists to evaluate sexual well-being, including aspects of sexual desire, behavior, and function, in adult patients with pituitary dysfunction. Participants were categorized into four groups: isolated anterior pituitary dysfunction (APD), isolated posterior pituitary dysfunction (arginine vasopressin deficiency, AVP-D), combined anterior and posterior pituitary dysfunction (Panhypopituitarism, PHP), and those with pituitary conditions without hormonal deficiency or excess (e.g., non-functioning pituitary adenomas). A Mean Global Index of Sexual Dysfunction (range: 0–3) was calculated using the Sexual Behavior Questionnaire. Sexual desire was assessed separately for dyadic (partnered) and solitary (individual) contexts using the Sexual Desire Inventory (SDI-2), with total scores ranging from 0 to 78, where higher scores reflect stronger desire. Total scores were compared between groups and adjusted for sex, age, and comorbidities.
Results
Between August and October 2024, 326 patients participated in the survey. The median age was 51 years [42–60], with 79% female participants, and the median duration of pituitary dysfunction was 8 years. Participants were categorized as follows: APD (44%), AVP-D (18%), PHP (26%), and non-hormonal pituitary disorders (12%). The most common etiologies were pituitary tumors or cysts (62%). 51% of patients were undergoing hormone replacement, while 28% had hormone excess. Sexual dysfunction and low sexual desire (median range: 20, [42–60]) were highly prevalent across all subgroups, with reference values of 38-42 in a healthy population. The highest severity was reported in patients with PHP. Sexual dysfunction was significantly correlated with sex, hormonal deficiencies, and comorbidities.
Conclusion
Sexual dysfunction is a prevalent and clinically significant issue in patients with pituitary dysfunction, affecting all subtypes. These findings highlight the importance for routine assessment and targeted treatment in this patient population. Further research is needed to better understand the underlying mechanisms and identify effective therapeutic approaches.

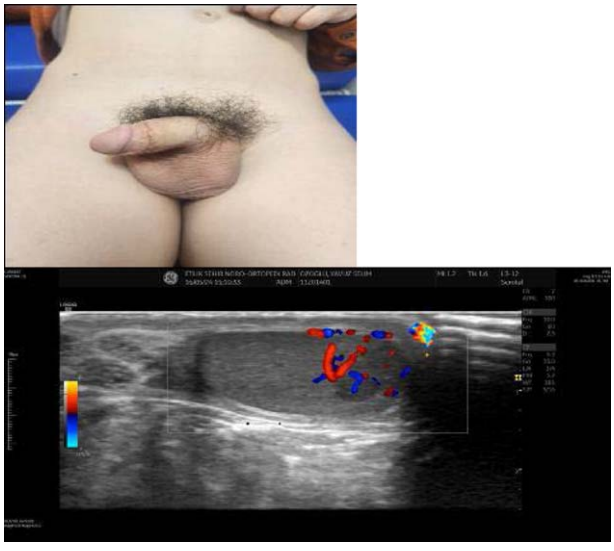
A case of leydig cell tumor presenting with peripheral precocious puberty

Emine Şeyma Eken[1,2], Meltem Korkmaz Vural[1,2], Keziban Aslı Bala[1,3], Firat Serttürk[1,4], Erdal Kurnaz[1,2], Melikşah Keskin[1,2], Halit Üner[1,5], Şule Yeşil[1,6] & Şenay Savaş Erdeve[1,2]
[1]Ankara Etlik City Hospital, Pediatric Endocrinology Clinic, Ankara, Türkiye; [2]Ankara Etlik City Hospital, Pediatric Endocrinology Clinic, Ankara, Türkiye; [3]Ankara Etlik City Hospital, Ankara, Türkiye; [4]Ankara Etlik City Hospital, Pediatric Surgery clinic, Ankara, Türkiye; [5]Ankara Etlik City Hospital, Pathology Clinic, Ankara, Türkiye; [6]Ankara Etlik City Hospital, Pediatric Oncology Clinic, Ankara, Türkiye.

Introduction
Leydig cell tumors are sex cord-stromal gonadal tumors originating from Leydig cells. Although rare, accounting for 1-3% of all testicular tumors, they are the most common hormone-secreting testicular tumors. These tumors have been found to be associated with peripheral precocious puberty. In this study, we present a case of Leydig cell testicular tumor in a patient presenting with peripheral precocious puberty. **Case:**A 5-year-and-12-month-old male patient presented to our outpatient clinic with complaints of pubic hair growth. His medical history revealed that he had no known chronic illnesses, hospitalizations, or medication use. On physical examination, his height was 125.2 cm (2.64 SDS), body weight was 32.9 kg (3.22 SDS), body mass index was 20.99 kg/m^2 (2.66 SDS), and target height was 175 cm (-0.19 SDS). His genetic alignment was +2.83 SDS. The right testis measured 6 mL, the left testis measured 4 mL, and his stretched penile length was 7 cm. Pubic hair was noted at Tanner stage 3, and axillary hair was also present (Image 1). The patient's complete blood count, biochemistry, and thyroid function tests were normal. His FSH was <0.3 IU/l(0.2-2.1), LH was 0.36 IU/l(0.1-1.3), total testosterone was 301 ng/dl (2.5-32), and AFP and β-HCG were negative. His bone age was consistent with 11 years. Scrotal imaging showed the right testis measured 24$\times$14$\times$14 mm, the left testis measured 15$\times$10$\times$11 mm, and a lesion with increased vascularity was noted in the



right testis parenchyma, measuring 14x7x12 mm, presenting as a hypoechoic area resembling a mass (Image 2). An LH-RH stimulation test revealed a peak LH of 0.85 IU/land peak FSH of 1.21 IU/l,which was consistent with peripheral precocious puberty. The patient underwent a frozen-section guided right testis preserving mass excision, and the pathological diagnosis was Leydig cell tumor consisting of large, eosinophilic, and granular cytoplasm cells, measuring 1.2 cm in diameter. The surgical margins were reported as intact. Follow-up scrotal and abdominal ultrasonography performed one month later were normal, and subsequent gonadotropin tests showed FSH: 4.72 IU/l(0.2-2.1), LH: 3.89 IU/l(0.1-1.3), and total testosterone: 108 ng/dl (2.5-32). Considering the possibility of central precocious puberty, GnRH analog treatment was started.

Conclusion

Leydig cell tumors are a cause of peripheral precocious puberty, and these patients typically present with a testicular mass, pubic hair growth, elevated testosterone, and low gonadotropin levels. Scrotal imaging is essential in these cases. With testis-preserving surgery, the prognosis is generally favorable, but patients should be carefully monitored for the potential development of central precocious puberty.

The association of neutrophil/HDL ratio, plasma atherogenic index and several cardiovascular risk scoring systems in acromegaly

Gökçen Ünal Kocabaş[1], Damla Kuşat[1], Elif Azarsiz[2] & Banu Sarer Yurekli[1]
[1]Ege University, Endocrinology, Izmir, Türkiye; [2]Ege University, Clinical Biochemistry, Izmir, Türkiye.

Acromegaly is associated with an increase in cardiovascular risk factors and cardiovascular disease mortality, and endothelial dysfunction. Acromegaly is also associated with subclinicasl inflammation. There is growing interest in indices derived from complete blood count due to the small cost and easy accessibility. Research has shown that Neutrophile-leucocyte ratio and platelet- leucocoyte ratio are higher in acromegalic patients compared to non-functioning pituitary adenomas. The neutrophil to HDL-cholesterol ratio (NHR) is a composite marker reflecting inflammation and lipid metabolism. NHR is a strong predictor of cardiovascular disease in many studies. To date, there are no studies of NHR in acromegaly. In this study, we aimed to determine hematological markers and the relationship between cardiovascular risk scores in acromegalic patients and healthy controls.

Methods

We retrospectively evaluated the hematological markers and lipid profiles of acromegaly patients and healthy controls. We calculated SCORE-2 and Framingham risk scoring systems and SCORE-DM system for diabetics. The patients with established cardiovascular disease were excluded.

Results

126 of the 204 patients were acromegaly and 78 were age and gender matched controls. There was no significant difference in Framingham and SCORE risk scores, neutrophile-leucocyte ratio(NLR), platelet-lymphocyte ratio (PLR) atherogenic index of plasma (AIP), neutrophile-HDL ratio(NHR) and platelet HDL ratio(PHR)between acromegaly and control groups. According to the remission status, the studied parameters did not show statistically significant difference. In the acromegaly group GH levels were positively correlated with SCORE risk (r^2:0.303, $P = 0.01$)IGF-1 levels showed a weak positive correlation with NHR(r^2:0.202, $P = 0.028$).

Discussion

We failed to demonstrate any significant difference in CBC derived indices of inflammation in acromegaly patients. Further studies indicating the effects of treatment modalities along with other indices of atherosclerosis are needed to determine the role of CBC derived parameters in acromegaly and atherosclerosis.

Impact of somatostatin analogues on glycaemic control in patients with neuroendocrine tumours: a retrospective observational study

Shahriar Khan Shahjada[1], Atul Kalhan[2] & Mohid Khan[3]
[1]Prince Charles Hospital, Merthyr Tydfil, United Kingdom; [2]Royal Glamorgan Hospital, Llantrisant, United Kingdom; [3]University Hospital of Wales, Cardiff, United Kingdom.

Introduction

Long-acting somatostatin analogues (SSAs), such as Octreotide and Lanreotide remain the main stay of medical management of Neuroendocrine tumours (NETs). SSA use has been observed to impact glucose homeostasis based on results from randomised clinical trials. Although, there are only a limited number of studies which have appraised evidence from real-world clinical practice related to long term impact of SSA on glycaemic control.

Objective

The primary objective of our retrospective observational study was to evaluate impact of long acting SSA on glycosylated haemoglobin (HbA1c) which remains the most commonly used parameter to analyse glycaemic control.

Methodology

By using South Wales NET tertiary clinic electronic data base, we identified all the patients with confirmed diagnosis of NET who were initiated on SSA analogues from year 2014-2024. The NET patients were further sub-divided into 2 sub-groups: with or without Diabetes (prior to initiation of SSA therapy). The baseline clinical and biochemical parameters were recorded with focus on capturing data related to glycaemic control. Changes in body weight, medication dose and/or regimen and HbA1C levels were evaluated post initiation of SSA therapy.

Results

We identified 98 patients ($n = 98$) with confirmed diagnosis of NET who were initiated on SSA therapy from year 2014-2024. 80 of these NET patients were not known to have diabetes prior to initiation of SSA therapy. It was interesting to note that 12 (15%) out of these 80 NET patients, developed diabetes on long term follow up as evidenced by increase in HbA1C to $\geq$ 48 mmol/mol (mean HbA1c increase by 10.1 mmol/mol). The mean duration (post SSA initiation) for developing diabetes in this cohort was 27 months. In the other sub-group of 18 patients who were known to have diabetes prior to SSA initiation, 14 were observed to have an increase in HbA1c levels by an average 16.3 mmol/mol. Across the entire cohort, a mean HbA1C increase of 4.1 mmol/mol was documented post-SSA treatment.

Conclusion

Our retrospective observational study data suggests that long term SSA use in patients with NET has a modest detrimental impact on glycaemic control in patients with or without pre-existing diabetes. The sub-group of patients with pre-existing diabetes being initiated on SSA therapy need to be counselled about importance of self-monitoring of blood glucose (SMBG) levels. In case the SBMG readings reflects sub-optimal glycaemic control, a close liaison with primary and secondary care diabetes services can improve clinical outcomes.

JOINT2631

A case report on timely surgical intervention in pituitary apoplexy and cavernous sinus invasion

Furhana Hussein[1], Dalya Sadulah[1], Ahmed Al-ghrairi[1], Lina Eltayieb[1], Bashir Mahamud[1], Ehsan Shakoor[1], Farhan Asghar[1], Lilian Auguste[1] & Gideon Mlawa[1]
[1]Barking, Havering, and Redbridge University Hospitals NHS Trust, Romford, United Kingdom, London, United Kingdom.

Introduction

Pituitary apoplexy is a rare but potentially life-threatening emergency characterized by sudden haemorrhage or infarction of the pituitary gland requiring immediate medical attention. The urgency is heightened when cavernous sinus invasion is present as this significantly increases the risk of neurovascular compromise and other severe complications. Here we present a case of pituitary apoplexy complicated by cavernous sinus invasion which was successfully managed with transsphenoidal surgery. This highlights the critical importance of early surgical intervention in achieving favourable outcomes and preventing complications such as cranial nerve damage, carotid artery injury, and cavernous sinus thrombosis.

Case Presentation

A 50-year-old male presented with a 1-day history of severe headaches, vomiting, and right-sided ptosis. Initial investigations including blood tests and imaging were conducted to rule out other emergencies. Laboratory results showed IGF-1 of 113 ng/ml, prolactin of 86 ng/ml, cortisol of 41 nmol/l,TSH of 3.43 mIU/l,T4 of 5.8 µg/dl, LH of 12 IU/l,and FSH of 11 IU/L. An MRI revealed a well-circumscribed pituitary mass in the right paracentral region with invasion into the right cavernous sinus, measuring 3x2x1.5 cm. The patient's medical history included excess alcohol intake and type 2 diabetes mellitus. The patient underwent transsphenoidal surgery without complications leading to the resolution of right-sided ptosis. Postoperatively, he is on hormone replacement therapy with levothyroxine, testosterone and hydrocortisone.

Conclusion
Pituitary apoplexy complicated with cavernous sinus invasion warrants prompt surgical decompression to prevent neurovascular compromise of important structures as well as control bleeding within the cavernous sinus. Left untreated pituitary apoplexy with cavernous sinus invasion can lead to serious complications. The literature supports that immediate surgical decompression, coupled with hormone replacement therapy is essential for optimal patient recovery and long-term prognosis.
Questions for discussion
- Should surgical intervention be done as an emergency or electively?.
- If there is recurrence, would you advocate for further surgical intervention?.
- What is an appropriate timescale for follow-up for this patient?.

Surgical management of pituitary adenoma: a single-centre experience

Furhana Hussein[1], Lina Eltayieb[1], Mohammed Mohammed[1], Shoayeb Sarwar[1], Irshad Mohamed[1], Ahmad Alnashrati[1] & Gideon Mlaway[1]
[1]Barking, Havering, and Redbridge University Hospitals NHS Trust, Romford, United Kingdom, London, United Kingdom.

Introduction
A pituitary adenoma is a tumour of the pituitary gland and is further classified by their size, cell type and hormone secretion. Microadenoma when the tumour is < 1cm and macroadenoma > 1cm. This is further classified if they are functioning (producing excess hormone) or non-functioning (no hormonal excess). Cell types include Prolactinoma, somatotroph, corticotroph, thyrotroph, and gonadotroph. In rare cases can also get malignant tumour. Around 1 in 10 people will develop pituitary adenoma in their lifetime. Treatment depends on the type of pituitary adenoma and includes medication, surgery and radiation therapy. Prolactinomas are the most common type of pituitary adenoma in the UK (40-60%) and then are non-functionating tumours.
Aim
of this study was to look at the diagnosis and surgical management of pituitary adenomas referred at Queen's Hospital, London, UK (BHRUT–Barking, Havering and Redbridge University Hospitals NHS Trust) in 2015-2022 (7 years).
Method
Retrospective single-centre study looking at patients referred for surgical management of pituitary adenoma between 2015-2025.
Results
55 patients were identified of which 42% female and 58% male. The age of presentation was more common in the age range of 71-80years (35%) and the least common was age range 31-40years (11%). Majority of the pituitary adenomas that underwent surgical intervention were functioning (65%), whereas 20% were non-functioning and rest compromised of malignancy or apoplexy. The most common functioning type of pituitary adenoma was gonadotroph (50%), then acromegaly 20% and least common in general was malignancy 5%. Corticotroph releasing were 15% and prolactinoma were 7.5%.
Conclusion
Our single-centre study showed that majority of pituitary adenoma referred for surgical intervention were functioning of which most common was gonadotroph and second most common was acromegaly. It is important that the hormone profile and imagining is done in a timely manner and if symptoms are worsening then to timely refer patient for surgical intervention when medical management is resolving the symptoms. This helps present complications and provides a better patient outcome. A Multidisciplinary (MDT) approach is vital and is individualised for each patient.

JOINT2595

A retrospective study of clinicopathological features of growth hormone and prolactin co-secreting pituitary tumors

Brendan Dillon[1], Shruti Shah[2], Samhitha Mada[3], Sarra Belakhoua[4] & nidhi agrawal[1]
[1]New York University Langone Medical Center, Holman Division of Endocrinology, Diabetes and Metabolism, Department of Medicine, New York, United States; [2]New York University Grossman School of Medicine, New York, United States; [3]The City University of New York School of Medicine, New York, United States; [4]New York University Langone Medical Center, Neuropathology Service, Department of Pathology, New York, United States.

Co-secretion of growth hormone (GH) and prolactin occurs in approximately 25% of GH-secreting tumors. Monomorphic expression of a single cell type producing both GH and prolactin occurs in the mammosomatotroph adenoma (MSA), while dimorphic expression of two cell types separately secreting GH and prolactin occurs in the mixed somatotroph-lactotroph adenoma (MSLA). Compared to pure GH-secreting adenomas, co-secreting adenomas are associated with younger age, larger tumor size, greater tumor invasion, and more frequent presurgical hypopituitarism. We retrospectively reviewed the medical records of patients at our medical center with a histopathological diagnosis of MSA ($n = 19$) or MSLA ($n = 3$) following surgical resection from 2021 to 2024. The mean age at surgery was 48 years and 64% were female. Preoperative symptoms included headache (68%), irregular menses (60%), acromegalic features (59%), arthralgias (45%), and visual disturbances (36%). Comorbidities included hyperlipidemia (59%), glucose intolerance (45%), colon polyps (45%), thyroid nodules (41%), hypertension (36%), obstructive sleep apnea (36%), and carpal tunnel syndrome (27%). Preoperatively, the average prolactin level was 53 ng/ml, GH level 17 ng/ml, and IGF-1 level 856 ng/ml. Radiographically, the majority were macroadenomas (91%) with cavernous sinus invasion in 45%, suprasellar extension in 41%, and optic chiasm compression in 23%. T2-hypointensity was noted in 27%. Tumor size did not correlate with IGF-1 levels. All tumors stained positive for GH, prolactin, and PIT-1. Somatic mutations in GNAS were detected in 32%. Resection was subtotal in 7 cases (32%). The postsurgical remission rate was 50%. The frequencies of postoperative hypogonadism, hypothyroidism, and adrenal insufficiency were 27%, 18%, and 45%, respectively, with recovery in 17% and 25% for hypogonadism and adrenal insufficiency, respectively. There was one case of postoperative total anterior hypopituitarism and no cases of permanent AVP deficiency. With regards to methylation data, the identified pituitary adenoma classes were pituitary adenoma, STH densely granulated, group B ($n = 14$), pituitary adenoma, STH sparsely granulated ($n = 5$), pituitary adenoma, TSH ($n = 2$), and pituitary adenoma, STH densely granulated, group A ($n = 1$) with a positive calibrated score (>0.9) in 82%. Both cases of pituitary adenoma, TSH class were associated with a score below threshold. To our knowledge, this is the first study examining the different methylation classes in GH and prolactin co-secreting tumors. Further investigation is needed to better characterize these co-secreting adenomas and how they differ both from their pure GH-secreting counterparts as well as amongst themselves to guide prognosis and management with consideration for tumor methylation data as a potential tool.

Clinical results in an aggressive coricotroph adenoma with a unique molecular expression profile expressing high levels of different oncogenic splicing variants (SSTR5TMD4, In1-ghrelin and GHRH-R)

Susana Mallea-Gil[1], Raul M Luque[2], Bibiana Coca[1], Cindhy Castro Basurto[1] & Carolina Ballarino[1]
[1]Hospital Militar Central, Endocrinology, Buenos Aires, Argentina; [2]Maimonides Institute for Biomedical Research of Córdoba (IMIBIC); Department of Cell Biology, Physiology, and Immunology, University of Córdoba, Spain, Córdoba, Spain.

Silent corticotrope pituitary adenomas (SCPAs) comprise approximately 20% of all corticotrope adenomas and 3-19% of non-functioning pituitary adenomas (NFPAs), and are considered high-risk pathologies. Therefore, appropriate treatment decisions and a close follow-up should be tailored to improve patient outcomes. A 43-year-old male patient with fatigue, decreased libido, frontal headaches, right eye strabismus and ptosis was referred to our Endocrinology Department due to an invasive giant pituitary tumor in November 2022. MRI revealed a large sellar-mass with invasion of both cavernous sinus with right dominance and progression towards the sphenoid sinus, and ethmoidal cells on the right and clivus [diameter: 70 mm anterior-posterior, 73 mm cranio-caudal, and 57 mm transversal; pituitary stalk presented slight displacement to the left]. Transcranial surgery was conducted to decompress the optical nerve of the right eye, with improvement in visual acuity, ptosis and headaches. Post-surgery lab tests revealed normal TSH, FT4, cortisol, prolactin, IGF-I levels, but low LH, FSH and total free and bioavailable testosterone levels. A second surgery (transsphenoidal) was performed and pathological report showed a neoplastic

proliferation that infiltrated the stroma below the pavement cells with some intraluminal tumor emboli, increase in the mitotic number and absence of necrosis. Immunostaining and molecular studies showed: CK++, SYN+++, CK8.18++ with perinuclear rings, P53++, KI 67<1%, ACTH isolated positivity and negative prolactin/GH/TSH/LH/FSH/TSH/FSH and PIT 1, but T-PIT positive ++ nuclear and GATA 3 positive +++ in all cells. Moreover, tumor sample expresses high POMC levels (ACTH-precursor), DR1 (only dopamine-receptor subtype significantly expressed) and GHRH-R. Interestingly, oncogenic splicing events of key genes were significantly expressed in tumor sample, including high expression of the splicing-variant of the SSTR5 with 4 transmembrane-domains (SSTR5TMD4; no expression of other SSTRs was found), and of In1-ghrelin and GHRH-R spliced-variants. Due to the extensive tumor persistence, we decided to begin Temozolomide in a multidisciplinary-session, but no response was found after receiving 4-cycles. PD-L1 expression and Microsatellite instability were negative. Then, Stereotactic Fractionated radiotherapy was performed. MRI showed slight decrease of the tumor size. Current treatment: cabergoline 2 mg/week, hydrocortisone and testosterone, being tumor stable and the patient is being closely followed-up. The treatment of aggressive NFPAs is a challenge because patients usually need combined therapies such as multiple surgeries, radiotherapy and oncologic drugs. Molecular studies are necessary to identify tumors' features to select adequate treatments. Oncogenic splicing variants expressed in this tumor might be associated to the aggressive-features found in this patient.

A fifteen-year-old boy with GH/PRL-secreting pituitary neuroendocrine tumor without excessive height growth

Kenta Watanabe[1], Yoshimi Okubo[1], Tae Kimura[1], Asako Tajima[1], Yudo Ishii[2], Miku Maeda[3], Takuhiro Kawahara[3] & Ichiro Miyata[1]
[1]The Jikei University School of Medicine, Department of Pediatrics, Tokyo, Japan; [2]The Jikei University School of Medicine, Department of Neurosurgery, Tokyo, Japan; [3]The Jikei University School of Medicine, Department of Pathology, Tokyo, Japan.

We have experienced a case of a fifteen-year-old boy with a past history of congenital hydrocephalus and past surgeries for spina bifida and myelomeningocele, who was referred to our department for the assessment of elevated IGF-1. The patient had been receiving a regular check-up at the neurosurgery department at our hospital, and a swelling of the pituitary gland was detected during a routine brain MRI but was considered a physiological change. At the age of fifteen, he developed chest pain, and upon examination at the local hospital, anterior mediastinum tumor and elevated IGF-1 level were found. After undergoing surgery for the tumor, further investigation was conducted for elevated IGF-1 at our department. He showed no excessive height, but he had enlarged hands and feet, and protruding brow bone and lower jaw. Brain MRI identified a nodular lesion in the pituitary with a low signal on T2-weighted imaging, and endocrinological evaluation was performed with several loading tests. Oral glucose tolerance test (OGTT) showed lack of growth hormone (GH) suppression. Thyrotropin-releasing hormone (TRH) stimulation test revealed elevated serum GH concentrations, and bromocriptine stimulation test resulted in a reduction of serum GH concentrations. Additionally, LHRH stimulation test showed an exaggerated LH/FSH response. We diagnosed him with acromegaly caused by an excessive GH production from the pituitary tumor, and transsphenoidal adenomectomy was performed. Pathological examination revealed PIT1-positive tumor cells, while TPIT and SF-1 were negative. Densely granulated GH secreting cells and sparsely granulated prolactin (PRL) secreting cells were detected, leading to the diagnosis of GH/PRL secreting pituitary neuroendocrine tumor (PitNET). Three months after surgery, a follow-up OGTT was conducted, and serum GH concentration was suppressed to normal range. Although elevated GH levels in childhood often leads to gigantism, our patient had no excessive height. We presume that this was because GH elevation occurred during adolescence when his bone maturation was nearly complete. Despite the exaggerated LH/FSH response, no secretion of LH/FSH was pathologically proved in the tumor cells. High LH and FSH levels may have been due to hydrocephalus, which can cause compression of the third ventricle, leading to GnIH suppression. While there are few reports on the coexistence of PitNET with other tumors, we found no cases of PitNET occurring with mediastinum tumor. This could be a rare case, and we plan on conducting further investigations.

Late onset isolated corticotrope deficiency induced by pembrolizumab

Ibtissem Oueslati[1], Nezha Hafsi[1], Helena Mosbah[1], Florence Torremocha[1] & Xavier Piguel[1]
[1]University Hospital of Poitiers, Department of Endocrinology, Poitiers, France.

Introduction
Pembrolizumab is a monoclonal anti-programmed death receptor-1 (PD-1) antibody that suppresses T-cell function. While it has gained approval for the treatment of numerous cancers, it is crucial to recognize the potential for serious immune-related adverse events, particularly concerning the endocrine system. Few cases of pembrolizumab-induced isolated corticotrope deficiency were reported in the literature. Herein, we report a new case of a late isolated corticotrope deficiency induced by pembrolizumab.
Observation
A 74-year-old woman was referred to the Department of Endocrinology for secondary adrenal deficiency. Her medical history was notable for hypertension, hypertrophic cardiomyopathy, cervical surgery for primary hyperparathyroidism, and lobectomy for non-small-cell lung carcinoma. Following a recurrence of her lung cancer, she underwent three chemotherapy regimens, including Carboplatin, Alimta, and pembrolizumab. Nine months post-initiation of chemotherapy, she presented with asthenia, weight loss, nausea, and vomiting. On physical examination, the patient had a weight of 69 kg, a height of 1.63 m, corresponding to a body mass index of 25.97 kg/m^2, an orthostatic hypotension, and a diffuse abdominal tenderness. The rest of examination was normal. The diagnosis of corticotrope deficiency was established based on a significantly low cortisol level of 28 nmol/lwith a low ACTH level of 4.9 ng/L. Other pituitary hormone levels were normal, confirming the diagnosis of isolated corticotrope deficiency. Magnetic resonance imaging (MRI) of the pituitary gland appeared normal, showing no tumors. The posterior lobe bright spot was intact, and the pituitary stalk was median and thin. The patient was treated with hydrocortisone and responded positively to the therapy.
Discussion
Corticotrope deficiency represents a potentially life-threatening complication of pembrolizumab treatment. Its clinical presentation can often be non-specific, as reported in this case. Previous reports indicate that the median onset of corticotrope deficiency following pembrolizumab administration is approximately 12 weeks. However, late-onset cases, including those occurring after the discontinuation of the drug, have also been documented. Regular monitoring of adrenal function is therefore essential during treatment and following the last dose of pembrolizumab.

The pituitary stone: a rare prolactinoma find

Nada Ait Kassi[1], Zouna Chayma[1], Habbadi Zineb[1], Fatima Toulali[1], Ghizlane Sabbar[1], Kaoutar Rifai[1], Hinde Iraqi[1] & Mohamed El Hassan Gharbi[1]
[1]Ibn Sina Hospital Mohamed V University, Endocrinology, Rabat, Morocco.

Introduction
Pituitary calcifications, though rare, pose diagnostic and therapeutic challenges. These lesions, frequently associated with prolactin-secreting adenomas, can present with varied clinical manifestations and often require multimodal management. This report highlights the clinical, biochemical, and imaging findings in a young female patient with a pituitary calcification, along with a review of therapeutic approaches.
Case Presentation
A 26-year-old woman, heterozygous for sickle cell disease, presented with bilateral milky galactorrhea persisting for three months. Her menstrual cycles were regular. Clinical examination confirmed provoked galactorrhea. Biochemical evaluation showed hyperprolactinemia at 38 ng/ml, confirmed on two subsequent measurements, and decreased free thyroxine (FT4) at 0.74 ng/dl, while the remaining pituitary hormonal panel was normal. MRI of the hypothalamic-pituitary region revealed a calcified anterior pituitary lesion measuring 3.7 × 3 mm, consistent with pituitary lithiasis. The patient was started on cabergoline (Dostinex) and levothyroxine replacement therapy, with plans for reevaluation after three months.
Discussion
Calcifications within the pituitary gland are rare, often linked to prolactinomas or other adenomas. They can impede tumor shrinkage despite appropriate medical

management. Cabergoline remains the first-line therapy for hyperprolactinemia, effectively reducing prolactin levels and ameliorating symptoms. Imaging plays a pivotal role in distinguishing calcified adenomas from other entities such as Rathke's cleft cysts or craniopharyngiomas. Histopathological analyses frequently reveal amyloid and calcium deposits, suggesting chronicity or degenerative processes.
Conclusion
The case underscores the importance of integrating clinical, biochemical, and imaging findings for accurate diagnosis and management of pituitary calcifications. Dopamine agonist therapy, complemented by hormonal replacement where necessary, remains the cornerstone of treatment. Longitudinal follow-up with imaging and biochemical monitoring is essential to assess therapeutic response and guide management in such rare cases.

Meningeal syndrome revealing craniopharyngioma of the sellar region: a case report

Rania Dassoufi[1], Sara Ijdda[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohamed 6 University Hospital of Marrakech, Endocrinology-Metabolic Diseases-Nutrition Department, Marrakech, Morocco.

Introduction
The most frequent clinical manifestations of sellar craniopharyngiomas are endocrinological disturbances or symptoms from masse effect such as visual impairment, headache, and rarely signs of intracranial hypertension. However, rare cases in the literature have been described mimicking a febrile meningeal syndrome, often in the context of an infected meningeal breche but rarely amicrobial due to meningeal irritation.
Case presentation
Patient aged 34, admitted to emergency initially for a febrile meningeal syndrome with intracranial hypertension consisting of vomiting, headache, fever between 39-40°C, with meningeal stiffness evident on clinical examination. As part of the emergency management following a lumbar puncture following a normal cerebral CT scan, the patient was immediately put on antibiotics while awaiting the results of additional tests which confirmed the biological infectious syndrome through an increase in CRP and white blood cells with a predominance of neutrophils. After transfer to the infectious diseases department, these tests were supplemented by cerebral MRI angiography, which revealed a sellar and supra-sellar lesional process measuring 22*20*35.8 mm, initially suggesting a cystic craniopharyngioma. Antibiotic therapy was discontinued in view of the normal results of the puncture and a progressive and spontaneous improvement in the paraclinical parameters. A posteriori and after stabilisation of the patient, we reconstructed her medical history revealing a tumour syndrome evolving for 4 months with amenorrhoea for 2 years, supported by the hypopysogram which had revealed panhypopituitarism with corticotropic insufficiency substituted first, thyreotropic insufficiency subsituted 72 hours later and gonadotropic insufficiency.
Discussion
It is commonly accepted that they are either diagnosed based on the presence of abnormal endocrinological secretion or by the compression of a surrounding structure. However, enlargement of a sellar craniopharyngioma can reach the meningeal structures, causing breaches with rinorrhea that can become infected and lead to true meningitis, or more rarely, simple irritation mimicking aseptic meningitis with meningeal syndrome, as in our patient in whom the pituitary adenoma had caused febrile meningeal syndrome.

JOINT343

Treatment of acromegaly patients with resistance to first-generation somatostatin receptor ligands (fg-SRLs)

Evgeny Pronin[1], Tatiana Alekseeva[1], Vyacheslav Pronin[1 2] & Mikhail Antsiferov[1 2]
[1]Endocrinological dispensary, Moscow Health Department, Moscow, Russian Federation; [2]Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russian Federation, Moscow, Russian Federation.

Among monohormonal densely&sparsely granulated somatotrophic tumors (DGSTs&SGSTs), SGSTs are more difficult to treat, as they are marked by invasive growth, recurrent course and refractoriness to drug therapy (DT) with fg-SRLs. Prioritized and undifferentiated use of fg-SRLs without considering ST receptor status inevitably leads to low efficacy of DT and negative life prognosis of patients with SGSTs.
Aim of this study
To investigate the reasons for low efficacy of fg-SRLs monotherapy and efficacy of combined administration of fg-SRLs&pegvisomant (PEG) for achieving acromegaly control.
Materials and methods
We retrospectively analyzed the efficacy of secondary DT of fg-SRLs in 62 acromegaly patients with a verified morphologic diagnosis who received prolonged forms of octreotide (20-30mg/28days) and lanreotide (120mg/28-56days). Based on final IGF-1 index (II) value, all patients were divided into 2 groups with II ≤ 1 [group 1(30 patients)] and >1 [group 2(32 patients)].
Results
In both groups patients did not differ in age of diagnosis [42.2 $\pm$ 12.2 vs. 41.0 $\pm$ 11.2 years($P = 0.68$)] and duration of treatment [31.1 $\pm$ 20.1 vs. 31.5 $\pm$ 19.0 months($P = 0.9$)]. In group 2 (resistant) patients had larger baseline II [3.1 $\pm$ 0.9 vs. 2.4 $\pm$ 0.8($P = 0.0025$)], larger residual tumor volume [1.9 $\pm$ 3.4 vs. 0.5 $\pm$ 1.3cm^3($P = 0.0391$)] and higher final II [1.7 $\pm$ 0.6 vs. 0.8 $\pm$ 0.2($P < 0.0001$)] compared to group 1. Low percentage of IGF-1 level reduction after 3-6 months of treatment in patients of group 2 [28.2 $\pm$ 22.0&26.6 $\pm$ 23.0% vs. 57.0 $\pm$ 22.6&61.3 $\pm$ 20.7%($P < 0.0001$)] is also different compared to patients of group 1, which indicates key importance of STs selective receptor sensitivity factor to fg-SRLs. In group 2 immunohistochemical analysis revealed high presence of patients with SGSTs [72%(23) vs. 37%(11); $P = 0.0075$], lower SSTR2 expression [7.1 $\pm$ 4.0 vs. 9.1 $\pm$ 3.7 scores(IRS); $P = 0.0479$], lower SSTR2/SSTR5 ratio [1.5 $\pm$ 1.2 vs. 3.4 $\pm$ 3.1($P = 0.0025$)] and higher proportion of cells with fibrous bodies [2.6 $\pm$ 0.8 vs. 2.1 $\pm$ 0.9 scores($P = 0.024$)] compared to group 1. Regarding cellular composition of STs, tumors from chromophobic cells were predominant in group 2 [69%(22) vs. 23%(7); $P = 0.0006$], tumors from intermediate-type cells were observed less frequently [25%(8) vs. 50%(15); $P = 0.046$] and tumors from eosinophilic cells were even less frequent [6%(2) vs. 27%(8); $P = 0.0285$] compared to group 1. To control acromegaly, patients in the resistant group were treated with combined therapy of fg-SRLs&PEG (18.4 $\pm$ 8.8mg/day) for 6-55 months, as a result of which 73% of patients achieved biochemical remission in the absence of significant adverse events. The final II value decreased from 1.7 $\pm$ 0.6 to 0.97 $\pm$ 0.4($P < 0.0001$).
Conclusions
1. Among the reasons for insufficient efficacy of fg-SRLs monotherapy high secretory activity, specificity of cellular composition of STs and low SSTR2 expression should be emphasized. 2. Combined use of fg-SRLs&PEG in refractoriness to fg-SRLs monotherapy contributes to achievement of biochemical remission in 73% of cases.

Indexes of liver steatosis and fibrosis in metabolically associated fatty liver in hypopituitarism

Dragana Miljic[1], Mirjana Doknic[1,2], Sandra Djurdjevic[3], Marko Stojanovic[2,4], Zvezdana Jemuovic[2], Ivana Cekic[2], Ivan Jevtic[2], Boris Kurcubic[2] & Marina Nikolic Djurovic[4]
[1]Medical Faculty, Belgrade University, Clinic for Endocrinology, Diabetes and Metabolic Disorders, Universitz Clinical Center of Serbia, Neuro-endocrinology, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Disorders, Clinical Center of Srbia, Neuroendocrinology, Belgrade, Serbia; [3]Faculty of Medicine, Belgrade University, Clinic for Endocrinology, Diabetes and Metabolic Disorders, Neuroendocrinology, Belgrade, Serbia; [4]Faculty of Medicine, Belgrade University, Belgrade, Serbia.

Aim
To investigate relationship between insulin resistance, hepatic steatosis and fibrosis in hypopituitarism.
Patients and Methods
Study included 282 hypopituitary patients (136 women and 146 men) aged 49.2 $\pm$ 15.1 years, body mass index 27.9 $\pm$ 5.8 kg/m^2, $n = 140$ (49.6%) due to non-functioning pituitary adenoma.
Results
Fatty liver on ultrasound was obesrved in 20.6% ($n = 58$). The metabolic syndrome (MetS), defined by IDF criteria, was present in 57.1% ($n = 161$) and 48.6% ($n = 137$) using NCEP ATP III. The LAP (171.8 $\pm$ 150.1 vs 54.6 $\pm$ 39.4, $P < 0.001$) and FLI (15.7 $\pm$ 15.5 vs 4.9 $\pm$ 9.8, $P < 0.001$) were significantly higher in patients with hypopituitarism and fatty liver, compared to those with

		Fatty liver						*P* value
		N	Mean	SD	Median	Perc. 25	Perc. 75	
FIB4	No	111	1.24	.87	1.10	.70	1.50	0.327
	Yes	41	1.25	.56	1.20	.90	1.60	
BARD score	No	109	2.28	.89	2.00	2.00	3.00	0.732
	Yes	37	2.35	1.06	2.00	2.00	3.00	
LAP	No	79	54.58	39.41	46.50	25.40	71.40	<0.001
	Yes	32	171.78	150.17	122.55	87.57	203.05	
FLI	No	64	4.87	9.85	1.17	.60	4.05	<0.001
	Yes	29	15.71	15.46	10.05	2.70	24.70	

hypopituitarism alone., while fibrosis scores FIB4 and BARD were not significiantly different between the two groups. Signifficant corellations were found between fatty liver disease, MetS and steatosis indexes LAP and FLI ($P <$ 0.001), but not with fibrosis indexes BARD and FIB4. HOMA IR and Matsuda index were siginificantly higher in patients with fatty liver compared to those with hypopituitarism alone and highly correlated with fatty liver findings on ultra sound, and steatosis indexes LAP and FLI ($P <0.001$), but not with indexes of liver fibrosis BARD i FIB4.

Conclusion

Indexes of fatty liver correlated with insulin resistance and ultrasound finding of fatty liver in patients with hypopituitarism, while no such correlation was observed with indexes of liver fibrosis. Liver steatosis but not fibrosis is fueled by insulin resistance and metabolic syndrome in patients with hypopituitarism.

Therapeutic challenges in male patients with prolactin-secreting pituitary adenomas

Mouna Elleuch[1], Yassmine Abdelkafi[1], Zaineb Fourati[1], Khouloud Boujelben[1], Mouna Mnif[1], Faten Haj Kacem Akid[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]

[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia.

Introduction

The management of prolactin-secreting pituitary adenomas in men presents unique challenges due to their frequent late diagnosis and aggressive presentation, especially in cases of macroprolactinomas or giant prolactinomas. This study aimed to evaluate therapeutic approaches and their outcomes in male patients with prolactinomas.

Methods

We conducted a retrospective, descriptive, and analytical study of 36 men treated for prolactin-secreting adenomas at the Endocrinology and Diabetology Department of Hedi Chaker University Hospital, Sfax. Treatment modalities included dopamine agonists, surgery, and radiotherapy, with assessments of their clinical, biological, and radiological responses.

Results

From a therapeutic perspective, 20 patients (62.5%) were treated with dopamine agonists alone, 12 patients (37.5%) underwent surgical excision combined with dopamine agonists, and 4 patients (11.1%) had undergone surgical excision at the time of diagnosis without any association with medical treatment, either before or after the surgical procedure. However, radiotherapy was not indicated for any patient in our study cohort. Regarding disease progression, 17 patients (47.22%) had regular follow-up with good therapeutic adherence, with an average follow-up duration of 49.27 $\pm$ 59.17 months, ranging from 1 to 180 months. Among them, 11 patients (30.56%) achieved remission, and 6 patients (16.67%) had a favorable outcome. Of those who achieved remission, 3 patients (27.27%) experienced a late relapse. However, no patient had an early recurrence. Treatment resistance was only observed in 3 patients. We investigated the effectiveness of dopamine agonists (DA) in reducing prolactin levels and controlling tumor volume. We demonstrated that, regardless of tumor size, Cabergoline is more effective in achieving normal prolactin levels at lower to medium doses when compared to Bromocriptine. However, we could not identify any statistically significant correlation between the different therapeutic approaches and their effect on tumor volume ($P = 0.440$). For patients who achieved clinical remission, they had a significantly smaller average tumor volume ($P = 0.008$) and a lower initial prolactin level ($P = 0.031$) compared to those with a favorable progression or post-treatment resistance.

Conclusion

The management of prolactin-secreting adenomas in men remains challenging due to frequent resistance to medical therapy, tumor aggressiveness, and treatment-related complications. While dopamine agonists are highly effective in most cases, surgery is indispensable for resistant or complicated tumors. Long-term follow-up is crucial to monitor recurrence and manage persistent complications.

JOINT1558

Endocrine-related adverse events in patient receiving combined immune checkpoint inhibition – a case report

Radina Dimitrova[1,2], savi shishkov[1,2], Zhenya Ruseva[1,2] & Mira Siderova[1,2]

[1]UMHAT "St. Marina", Clinic of Endocrinology and metabolic diseases, Varna, Bulgaria; [2]Medical University Varna, Second department of internal medicine, Varna, Bulgaria.

Introduction

In recent years, immune checkpoint inhibitors (ICI) have emerged as a powerful innovative therapeutic strategy in the treatment of various types of cancer. They exert their effect by targeting the immune response towards malignant cells, blocking the usual inhibitory pathways of T-cell regulation, thereby allowing T-cell mediated destruction of cancer cells. Cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) and programmed cell death 1 (PD-1) or its associated ligand (PD-L1) are major immune checkpoints that serve as targets for inhibition.

Case report

A male with known type 2 diabetes mellitus on treatment with metformin, SGLT-2 inhibitors, and GLP-1 receptor agonists, was diagnosed with poorly differentiated non-small cell lung carcinoma (T2N3M0) at 45 years of age. After chemotherapy and radiotherapy, immunotherapy with Ipilimumab (CTLA-4 inhibitor) and Nivolumab (PD-L1 inhibitor) was initiated. After the 5th cycle of immunotherapy, laboratory and imaging findings indicated autoimmune thyroiditis with hormonal constellation suggestive of secondary hypothyroidism (TSH 0.818 mIU/L; FT4 6.7 pmol/L; anti-TPO 68.97 IU/ml (<12)). Levothyroxine treatment was started with gradual dose titration up to 100 mg. After the 6th cycle of immunotherapy, the patient reported general fatigue, easy tiring with minimal physical effort, and dizziness. Laboratory tests revealed evidence of immune-mediated hepatitis and hypoglycemia, and hormonal analysis showed uncontrolled hypothyroidism and secondary hypocorticism, but with no data of hypogonadism and hyposomatotropism (ACTH <5.00 pg/ml, Cortisol 08:00h: 22.22 nmol/L; TSH 61.05 uIU/ml, FT4 5.69 pmol/L; LH 8.38 mIU/ml; FSH 6.48 mIU/ml; Total testosterone 12.5 nmol/L; Growth hormone 0.27 ng/ml (0.05 - 3.0); IGF-I 154.0 ng/ml (48 - 209)). MRI of the pituitary shows mild general non-homogeneity of the gland, suggestive of hypophysitis. Treatment with intravenous methylprednisolone at a dose of 20 mg daily was initiated until clinical stabilization, followed by oral hydrocortisone with gradual dose reduction to 20 mg daily. Additionally, after initiating corticosteroid replacement therapy, the dose of Levothyroxine was increased to 150 mg and switched to liquid form.

Conclusions

Immune checkpoint inhibitors have rapidly become an integral part of many cancer treatment regimens. These new drugs can significantly improve survival rates for several forms of cancer. However, these benefits come with the cost of autoimmune side-effects (especially when immunotherapy is combined) that affect a number of tissues, including the endocrine glands. Keywords: cancer, checkpoint inhibitors, autoimmune side-effects, endocrine glands.

Anterior pituitary deficiencies: a descriptive study in a pediatric hospital in cameroon

Marguerite Edongue Hika[1], Ben Patrick Moutlen[2], Cynthia Annette Soh Djoube[2], Maxime Wotol Ntonga[2], Aminatou Adamou[2], Catherine Fanny Mayoh N.[2] & Suzanne A Sap Ngo Um[1,2]

[1]Mother and Child Center of Chantal Biya Foundation, Pediatric, Yaoundé, Cameroon; [2]Faculty of Medicine and Biomedical Sciences of University of Yaounde I, Pediatric, Yaoundé, Cameroon.

Background

Anterior pituitary deficiencies can be isolated or combined, affecting single or multiple hormonal axes, often congenital. The clinical description varies based on the deficient hormones, and prevalence in Cameroon is not well-known.

Methodology
We conducted a retrospective descriptive study by examining 27 patient records followed at the Mother and Child Center of the Chantal Biya Foundation in Yaoundé, Cameroon. We analyzed the circumstances of discovery, anthropometric parameters during the first endocrinology consultation, the affected axes, and hormonal results when they were available. The data were recorded and analyzed using Microsoft Excel 2010.
Results
The median age of our participants was 16 [12.5–21] years, with a male predominance of 74%. In 59.3% of cases, children were brought to consultation by parents after an average symptom evolution duration of 3 [5–13] years. The reasons for consultation included short stature (78%), hypoglycemia (7.4%), and convulsions. The median age at diagnosis was 9 [1–4] years. Severe stunted growth was observed in 74% of cases, with a mean parental target height of 171 cm. Underweight was noted in 35% of cases, and severe malnutrition in 18.5% of cases. Hormonal assays were not always completed, with 37% of cases showing isolated GH deficiency and 63% showing multiple combined anterior pituitary deficiencies. The deficient axes included somatotropic (66.6%), corticotropic (22.2%), thyrotropic (25.9%), and gonadotropic (22.2%). No genetic diagnosis was made in any of the cases. Among the patients, only 33% had their cortisol levels measured, 40.7% had their FT4 levels measured, 37% had their IGF-1 levels measured, and 18.52% had their growth hormone levels measured. FSH/LH levels were measured at 18.5%, and bone age was assessed in 37%. The average bone age was 8.2 $\pm$ 3.19 years.
Conclusion
Anterior pituitary deficiencies are diagnosed late in our context. Parents raise the alarm when stunted growth is severe. In a context where hormonal assays are costly, emphasis should be placed on clinical surveillance and early warning. There is an interest in the genetic diagnosis of anterior pituitary deficiencies in our country.

Adrenal crisis after missed diagnosis of pituitary sarcoidosis: a case report

Marwa Salah[1]
[1]Faculty of Medicine, Alexandria University, Egypt, Internal Medicine, Endocrine Division, Alexandria, Egypt.

Sarcoidosis is a disease characterized histologically by multiple non-caseating granulomata without a clear infectious or toxic trigger, with an unclear aetiology. The prevalence of sarcoidosis in the Middle East population is not well known. The clinical features of patients with sarcoidosis in the Middle East appear to be like that reported in the world with female predominance than males. In many cases, the diagnosis of sarcoidosis was made based on intrathoracic biopsy. Neurosarcoidosis (NS) is a rare form of sarcoidosis, with hypothalamic-pituitary involvement being uncommon. We report a 27-year-old man presenting with nausea, vomiting, diarrhoea, abdominal pain, weight loss, bilateral neck swellings and generalized fatigue. The patient was admitted to the hospital for suspected acute gastroenteritis. He further developed mental confusion, arterial hypotension (90/60 mmHg), and hypokalaemia (2.6 mmol/L). Initial assessment revealed adrenal crisis, and the patient received parenteral hydrocortisone. Further hormonal evaluation revealed hypopituitarism with secondary hypothyroidism, adrenal insufficiency and diabetes insipidus Table 1. Magnetic resonance imaging demonstrated pituitary stalk thickening, initially suggestive of hypophysitis. CT chest reported enlarged bilateral hilar lymph nodes with noted bilateral lower lung lobes few sub-pleural consolidative patches suggestive of sarcoidosis. Biopsy was performed from the suspected cervical lesions showed granuloma confirming the diagnosis sarcoidosis. The patient started prednisolone 60 mg daily, tapered to 7.5 mg daily and he was maintained on replacement therapy with levothyroxine and desmopressin. The condition of the patient improved during follow up.

Table 1. Results of the basal laboratory investigations of the patient.

Variables (units)	Results	Normal range
Thyroid stimulating hormone, TSH (μIU/ml)	0.42	0.27–4.2
Serum free thyroxine, fT4 (ng/dl)	0.76	0.89-1.76
Serum free T3(pg/ml)	1.9	2.3-4.2
Serum cortisol 8:00 am (ug/dl)	0.5	3-25
Adrenocorticotroph hormone, ACTH (pmol/L)	1.4	1.5-14.7
Prolactin (ng/ml)	14	3.8-23
Potassium (mmol/L)	2.6	3.5-5
Sodium (mmol/L)	143	136-145
Calcium (mg/dl)	10	8-11
Phosphorus (mg/dl)	2.9	2.5-4.9
Albumin (g/dl)	4.2	3.4-5
Total Bilirubin (mg/dl)	0.59	Up to 1
Protein (g/dl)	6.5	5.7-8.2
ALT (U/L)	26	10-49
Creatinine (mg/dl)	0.9	0.5-1.3
BUN (mg/dl)	9	9-23
Blood Urea (mg/dl)	19	15-45
Uric acid (mg/dl)	4.6	3.5-7.2

Conclusion
We report a case of undiagnosed hypopituitarism initially presenting as a case of adrenal crisis with hypotension and gastrointestinal symptoms. The patient also displayed clinical diagnosis of pulmonary and pituitary sarcoidosis with secondary hypothyroidism and diabetes insipidus. The case highlights the importance of endocrine sequelae of sarcoidosis.

Students Scientific Group of the Medical University of Warsaw at the Department of Internal Medicine, Endocrinology and Diabetology, National Medical Institute of the Ministry of the Interior and Administration, Warsaw, Poland; [2]Students Scientific Group of the Medical University of Warsaw at the Department of Internal Medicine, Endocrinology and Diabetology, National Medical Institute of the Ministry of the Interior and Administration, Warsaw, Poland; [3]Medical University of Warsaw, Department of Pediatric Radiology, Warsaw, Poland; [4]National Institute of Medicine of the Ministry of the Interior and Administration, Department of Radiology, Warsaw, Poland; [5]National Institute of Medicine of the Ministry of the Interior and Administration, Department of Ophthalmology, Warsaw, Poland; [6]Center of Postgraduate Medical Education, Department of Radiology, Warsaw, Poland; [7]Mossakowski Medical Research Center, Polish Academy of Sciences, Department of Human Epigenetics, Warsaw, Poland.

Background
Parasellar lesions may affect the optic chiasm leading to visual symptoms, such as a constricted visual field. However, partial empty sella and empty sella—despite involving subarachnoid space herniation into the sella turcica—may not produce vision abnormalities. The purpose of this study was to assess if empty sella and partial empty sella are risk factors for visual field defects.
Material and Methods
Out of 594 patients who had undergone pituitary magnetic resonance imaging (MRI), we selected 43 patients diagnosed with empty sella or partial empty sella syndrome, who subsequently underwent ophthalmological examination (86 eyes) with visual field assessment via full-field 120-point screening test, MRI of the pituitary and optic nerves, and hormone profile.
Results
The evaluated eyes were divided into two groups: Group 1: the eyes of patients with empty sella and the pituitary measuring $<$ 3 mm craniocaudally (n = 46), Group 2: the eyes of patients with partial empty sella and the pituitary measuring $\geq$ 3 mm craniocaudally (n = 40). Patients from the study groups did not differ in terms of the extent of visual field defects (%) in the entire visual field (5.33 $\pm$ 9.00 vs. 4.27 $\pm$ 8.75, P = 0.455). Logistic regression analysis showed none of the following parameters: the pituitary craniocaudal diameter (OR 1.092; 95%CI [0.451–2.642], P = 0.846), pituitary volume (OR 0.995; 95%CI [0.987–1.003], P = 0.258), sellar volume (OR 1.00; 95%CI [0.999–1.001], P = 0.976), or MRI-measured optic nerve area (OR 1.002; 95%CI [0.996–1.008], P = 0.441) to be independent risk factors for defects in the entire visual field.
Conclusions
Neither the volume nor craniocaudal diameter of the pituitary is a risk factor for visual field defects.

GnRH analogs in pediatric practice: efficacy, safety, and side effects—a comprehensive review

Nada Alaaraj[1], Ashraf Soliman[1], Ahmed Elawwa[1], Noor Hamed[1], Fawzia Alyafei[1], Shayma Ahmed[1] & Noora AlHumaidi[1]
[1]Hamad Medical Corporation, Doha, Qatar.

Introduction
Gonadotropin-releasing hormone (GnRH) analogs are critical in managing central precocious puberty (CPP) in pediatrics, effectively halting pubertal progression and improving predicted adult height. Despite their clinical benefits, potential risks such as bone mineral density reduction, metabolic disturbances, and menstrual irregularities require careful evaluation, especially in long-term use. This review synthesizes recent literature to provide a detailed understanding of GnRH analogs' efficacy, safety, and potential side effects in pediatric applications.
Objectives
To evaluate the efficacy and safety of long-acting (3-month) vs short-acting (1-month) GnRH analogs in managing CPP in children, with a focus on growth outcomes, metabolic impacts, and side effects.
Methods
A literature review from 2009 to 2023 identified peer-reviewed studies assessing GnRH analog treatments in pediatrics. Key inclusion criteria included studies reporting clinical outcomes such as pubertal suppression, height outcomes, and metabolic effects. Table 1 provides an overview of the main findings from selected studies.
Results
• Efficacy: Long-acting GnRH analogs effectively suppressed pubertal progression and improved predicted adult height, comparable to monthly formulations. Ramos *et al*. (2021) reported an increase in height SDS and a reduction in BMI in 22 CPP patients treated with a 3-month formulation. Klein *et al*. (2020) showed effective pubertal suppression with 6-month leuprolide acetate. (Ramos *et al*., 2021), (Klein *et al*., 2020).
• Safety:.
• Bone health: Both 1-month and 3-month formulations had minimal impacts on bone density (Vatopoulou *et al*., 2020).
• Glucose metabolism: No significant alterations were reported (Yuan *et al*., 2015).
• Side effects: Some studies noted minor BMI increases and transient menstrual irregularities during initiation.
• Risks: Long-term suppression with depot preparations raised concerns about delayed recovery of the hypothalamic-pituitary-gonadal axis upon cessation, though these effects were largely reversible (Silverman *et al*., 2015).
Discussion
Both long-acting and short-acting GnRH analogs provide effective CPP management in pediatrics. Long-acting formulations offer enhanced compliance due to reduced injection frequency, which is particularly beneficial in children. However, they may pose challenges for quick dose adjustments and recovery post-treatment. Short-acting formulations allow for greater flexibility but require more frequent clinic visits, potentially affecting compliance.
Conclusions
GnRH analogs are highly effective and safe in managing CPP in pediatric populations. Long-acting formulations improve compliance and are well-tolerated, making them preferable in many cases. Monitoring for rare side effects, such as bone density loss or delayed recovery post-treatment, remains essential. Future research should explore long-term outcomes to optimize treatment strategies.

Cushing's disease and severe resistant hypertension: surgical challenges due to rare kissing carotids

Baltagi Myriam[1], Ibtissem Ben Nacef[1], Rihab Laamouri[1], Sabrine Mekni[1], Sawsen Essayeh[1], Rojbi Imen[1] & Khiari Karima[1]
[1]Hospital of Charles Nicolle, Tunis, Tunisia.

Background
A 44-year-old male (BM) was referred for severe, resistant hypertension managed with quadritherapy since age 41. Clinical evaluation revealed hypokalemia, facial plethora, adiposity with a rounded facial appearance, and lower limb muscle atrophy, raising suspicion of hypercortisolism.
Case Presentation
Biochemical investigations confirmed ACTH-dependent Cushing's disease with elevated ACTH levels (>20 pg/ml) and cortisol non-suppression on the dexamethasone suppression test. Pituitary MRI identified a microadenoma associated with "kissing carotids," a rare vascular anomaly characterized by the medialization of the internal carotid arteries. This malformation significantly increased the risk of vascular injury during transsphenoidal surgery, the standard treatment for Cushing's disease.
Management Challenges
The rare association of a pituitary microadenoma with "kissing carotids" complicated the surgical approach, necessitating multidisciplinary planning. Alternative therapies considered included medical management with steroidogenesis inhibitors, stereotactic radiosurgery, or bilateral adrenalectomy to control hypercortisolism.
Conclusion
This case illustrates the complexities of managing Cushing's disease in the presence of "kissing carotids," a rare but clinically significant vascular anomaly. Multidisciplinary collaboration and individualized treatment planning are essential to optimize safety and outcomes in such challenging scenarios.

Evaluation of alexithymia and quality of life in patients with acromegaly

Lala Soltanova[1], Bera Aygun[2], Cem Sulu[1], Senol Turan[3], Pinar Kadioglu[1] & Emre Durcan[1]
[1]Istanbul University-Cerrahpasa, Cerrahpasa School of Medicine, Division of Endocrinology, Metabolism and Diabetes, İstanbul, Türkiye; [2]Istanbul University-Cerrahpasa, Cerrahpasa School of Medicine, İstanbul, Türkiye; [3]Istanbul University-Cerrahpasa, Cerrahpasa School of Medicine, Department of Psychiatry, İstanbul, Türkiye.

Introduction
Alexithymia, defined as emotional 'blindness', is a personality structure characterized by difficulties in understanding one's own emotions, distinguishing them from physical arousal signals, and verbally expressing one's emotions to others. Alexithymia, which is a transdiagnostic risk factor for depression, anxiety and post-traumatic stress disorder, may be a psychological risk factor for quality of life in patients with. In this study, we aimed to assess psychopathological conditions such as alexithymia in patients with acromegaly and determine their impact on quality of life.
Materials and Methods
The study included a total of 120 consecutive patients with acromegaly who were followed at the Endocrinology and Metabolism Outpatient Clinic of the Cerrahpasa Faculty of Medicine. Sociodemographic and disease-related clinical follow-up data were obtained from the medical records of all patients. In addition, the Toronto Alexithymia Scale-20, consisting of 20 items, and the Acromegaly Quality of Life Questionnaire (AcroQoL), consisting of 22 questions, were used for quantitative scale assessment.
Results
A total of 120 patients with acromegaly (71 females and 49 males) were included in this study. The mean age of all participants was 47 $\pm$ 10 years and the median disease duration was 90 $\pm$ 68 months. When the remission status of the patients was evaluated, there was no significant difference between the groups in terms of disease duration (90 $\pm$ 66 vs. 85$\pm$36 months, $P = 0.153$). The total scores of alexithymia and subscales (difficulty identifying feelings, difficulty describing feelings, and externally-oriented thinking) scores were similar in patients with and without remission (51 $\pm$ 11.3 vs. 51.5 $\pm$ 12.7; 17 $\pm$ 5.5 vs. 16 $\pm$ 5.5; 12 $\pm$ 3.8 vs. 14 $\pm$ 4.1; 22 $\pm$ 4 vs. 22 $\pm$ 5; respectively, $P > 0.05$ for all). Since there was no control group in our study, we compared the alexithymia scores in a population-based other Turkish study with 503 healthy participants from the literature; we found that our patients had similar alexithymia scores (49.6$\pm$11.1 in the literature vs. 50.7$\pm$11.5 in our study). Finally, when classifying patients according to remission status and disease duration, we found no significant difference between the groups in terms of AcroQoL scores.
Conclusion
In the present study, we demonstrated that alexithymia and quality of life in patients with acromegaly do not change depending to remission status and disease duration and that this was comparable to population-based studies.

JOINT2151

Aggressive prolactinoma with failed temozolomide therapy: management strategies & literature review

Rayna Koshy[1] & Koshy Jacob[2]
[1]The Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom; [2]Eastbourne District General Hospital, Endocrinology, Eastbourne, United Kingdom

A 55-year-old male was diagnosed with aggressive macroprolactinoma (APRL) in 2001. He underwent transsphenoidal surgery (TSS) in 2002 and 2005, followed by radiotherapy and further craniotomy in 2009. Temozolomide, an oral alkylating chemotherapeutic agent, was initiated in 2009, achieving biochemical control for over a decade. Patient was panhypopituitarism, requiring hormone replacement (levothyroxine, hydrocortisone, & testosterone) & severe sight impairment due to bilateral optic atrophy. In 2024, he presented with tumour relapse evidenced by rising prolactin levels. MRI confirmed subsellar and left cavernous sinus recurrence. Clinically, he had severe stabbing pain in the left V1 region along with left cranial nerve VI palsy. A cycle of Temozolomide was given but failed to control prolactin levels or alleviate pain. TSS was then undertaken which resulted in temporary prolactin reduction, but levels soon rebounded. Multidisciplinary discussion was undertaken, and tumour histology was analysed. Immunohistochemistry for DNA mismatch repair proteins (MSH2, MSH6, MLH1, PMS2) revealed absent MSH6 staining but others positive. Ki-67 proliferation index was 12%, and bone invasion confirmed aggressive behaviour. The findings were consistent with an aggressive prolactinoma/PITNET (WHO 2022). The patient is now undergoing radiotherapy, with further chemotherapy options being explored. Whole genome methylation and next-generation sequencing are underway to guide future treatment.

Conclusion

Aggressive prolactinomas are a rare subset of pituitary tumours. Effective management requires a multidisciplinary approach incorporating surgery, radiotherapy, and systemic therapy. We present a case of an aggressive prolactinoma successfully controlled with Temozolomide, from 2009 until 2022. However, in 2024, tumour recurrence demonstrated resistance to Temozolomide therapy. Immunohistochemical analysis of tumour tissue revealed absent MSH6 staining, suggesting a potential mutation in the *MSH6* gene. Loss of MSH6 expression has been associated with poor response to temozolomide therapy, as highlighted in a study where intact MSH6 correlated with a favourable treatment response. [1] This case underscores the importance of molecular profiling in guiding therapeutic decisions for aggressive pituitary tumours. The observed MSH6 loss may provide an explanation for acquired resistance to Temozolomide and suggests the need for alternative treatment strategies, such as immune checkpoint inhibitors or other targeted therapies. Multidisciplinary management remains essential in optimizing outcomes for these challenging cases.

Systematic review of cardiometabolic outcomes in young people with gender dysphoria and the impact of puberty blockers

Jennifer McKechnie[1,2], Kirsty mginley[3], Angela Lucas-Herald[3,4], Christian Delles[3], Avril Mason[2] & SC Wong[1,2]
[1]Bone, Endocrine, Nutrition Research Group in Glasgow (BEN-G), Human Nutrition, University of Glasgow, Glasgow, United Kingdom; [2]Department of Paediatric Endocrinology, Royal Hospital for Children Glasgow, Glasgow, United Kingdom; [3]School of Cardiovascular and Metabolic Health, University of Glasgow, Glasgow, United Kingdom; [4]Development Endocrinology Research Group, School of Medicine, University of Glasgow, Glasgow, United Kingdom

Background

There is evidence of an increased risk of cardiovascular disease in transgender adults compared to the cisgender population. It is unclear whether this is secondary to hormonal treatment, or if individuals with gender dysphoria inherently have a higher baseline risk for cardiometabolic complications. Data on the safety and efficacy of gonadotrophin-releasing hormone analogues (GnRHa) is limited in adolescents with gender dysphoria.

Aim

This systematic review aims to assess the cardiometabolic status in treatment-naive adolescents with gender dysphoria and evaluate the impact of GnRHa on these outcomes.

Methods

Three databases (Embase, Medline and Cochrane Library) were searched to April 2024 for studies which evaluated cardiometabolic outcomes in adolescents with gender dysphoria <18 years and/or those who had had been treated with GnRHa. Quality assessment was performed by two independent reviewers using an adapted version of the Newcastle-Ottawa Scale for cohort studies in gender dysphoria. The Preferred Reporting Items for Systematic Reviews and Meta-analyses reporting guidelines were used.

Results

Ten pre-post studies and five cross-sectional studies published between 2014 and 2023 fulfilled eligibility criteria. A narrative synthesis was performed. Quality assessment identified one high quality, twelve moderate quality and two low quality studies. Seven studies (47%) provided data on baseline characteristics and ten studies (67%) provided data on the impact of GnRHa. There was a total of 3772 adolescents with gender dysphoria along with 78792 age-matched cisgender controls. Multiple studies reported an increased prevalence of overweight and/or obesity or an increased BMI z-score in adolescents with gender dysphoria at baseline. There was no evidence of significant change in BMI following treatment for approximately one year. Limited and/or conflicting evidence was available in relation to body composition, blood pressure and metabolic markers at baseline and following GnRHa treatment.

Conclusion

This systematic review found an increased risk of excess weight in young people with gender dysphoria. There was no evidence of an increase in BMI with GnRHa treatment. Due to limited data, no definitive conclusions can be drawn about other cardiometabolic outcomes in adolescents with gender dysphoria, either at baseline or following pubertal suppression. Longitudinal prospective studies with standardized designs and key outcome measures are essential for advancing knowledge in this area.

Obstructive sleep apnea in patients with acromegaly

Mariia Berlovich[1], Kristina Vazagova[1], Margarita Perepelova[1], Larisa Dzeranova[1], Ekaterina Pigarova[1], Irina Belovalova[1] & Ivan Dedov[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction

Acromegaly is a severe neuroendocrine disorder caused by chronic excessive secretion of growth hormone (GH) and insulin-like growth factor 1 (IGF-1) in individuals who have completed their physiological growth. The most common causes of mortality in acromegaly are cardiovascular and cerebrovascular diseases, as well as respiratory system pathologies. Sleep-disordered breathing worsens the quality of life and increases the risk of various cardiovascular complications. It is essential to emphasize the importance of timely diagnosis of the disease and the development of optimal treatment pathways to prevent the progression of complications.

Objective

To analyze the referral process for patients with acromegaly to a sleep specialist and the possibilities for conducting diagnostic assessments.

Materials and Methods

A survey of specialists from various fields using a questionnaire.

Results

A total of 171 specialists participated in the survey, with the majority being endocrinologists (81.9%), followed by dentists (7.6%), pediatric endocrinologists (4.7%), maxillofacial surgeons (1.75%), and physicians from other specialties (4.1%). Among the respondents, 71.9% of specialists had experience working with patients suffering from acromegaly. However, among them, 68.4% did not refer patients to a somnologist due to the paid nature of the process, while 29.2% encountered a lack of specialists who could assess sleep, diagnose sleep apnea, and recommend treatment methods such as CPAP. According to the survey data, 81.9% of physicians believe that somnological assistance for such patients is inadequate, highlighting the need for improved access to specialized care and referrals in the field of somnology for patients with acromegaly.

Conclusions

This study demonstrates the inadequacy of the diagnosis and treatment provided to patients with acromegaly suffering from apnea. According to the results obtained, this is related to the inaccessibility of free consultations and the conduct of cardiorespiratory monitoring. The analyzed data will serve as a foundation for

improving the pathway for patients with acromegaly, which could significantly enhance the quality of medical care and improve the quality of life for patients.

Case report: infectious hypophysitis as a complication of sphenoiditis

Emna Naccache[1], Chayma Bel Hadj Sliman[1], Ibtissem Ouselati[1], Elyes Kamoun[1], Mariem Yazidi[1], Fatma Chaker[1], Nadia Khessairi[1] & Melika Chihaoui[1]
[1]La Rabta Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
Hypophysitis, an inflammation of the pituitary gland, is a rare condition that can be caused by infections, autoimmune disorders, or tumors. When complicated by sphenoiditis, it poses diagnostic and therapeutic challenges. This case report describes a 51-year-old male patient diagnosed with sphenoiditis complicated by infectious hypophysitis.
Case Presentation
A 51-year-old man, with no significant past medical history, presented with a complaint of persistent headaches, fatigue, somnolence, and rhinorrhea. These symptoms prompted him to seek consultation with the ear, nose, and throat(ENT) department. Upon examination, imaging was performed, including facial MRI and pituitary sections. The MRI revealed bilateral sphenoiditis. Additionally, there wasan evidence of hypophysitis with pituitary enlargement and an 18mm intrasellar collection. These findings were indicative of an infectious process affecting both the sphenoid sinus and the pituitary gland. The patient was immediately started on intravenous antibiotic therapy for 15 days. Biological assessments revealed anterior pituitary dysfunction: Specifically, the cortisol level was markedly low (2ug/dl), consistent with corticotropic insufficiency, and low FT4 levels (0,67 ng/dl) and a normal TSH level (1,3 mUI/l), consistent with thyrotropic insufficiency. The patient was placed on corticosteroid and thyroid hormone replacement therapy. There were no complaints of erectile dysfunction or libido reduction. Prolactin and testosterone levels were within normal limits The patient showed marked improvement, with complete resolution of headaches, asthenia, and somnolence. A follow-up MRI at three months confirmed the resolution of sphenoid sinusitis and the disappearance of the intrasellar mucocele. No additional complications were observed.
Conclusion
This case highlights the rare and complex link between infectious sphenoiditis and hypophysitis, leading to anterior pituitary insufficiency. Early diagnosis and prompt management, including targeted antimicrobial therapy and hormone replacement, are crucial for optimal outcomes. Clinicians should remain vigilant for pituitary involvement in patients with sinusitis and hormonal imbalances, especially when other causes of pituitary dysfunction are absent.

Introduction
Thyrotropin-secreting pituitary adenomas (TSH-omas) are rare causes of hyperthyroidism, accounting for 0.5% to 2% of all pituitary adenomas, with an estimated incidence of 1 to 2 cases per million. These tumors autonomously secrete TSH, leading to inappropriate stimulation of the thyroid gland and subsequent hypersecretion of thyroxine and triiodothyronine. Unlike other thyroid disorders, TSH-omas exhibit equal gender distribution and are typically diagnosed around the age of 46 $\pm$ 6 years. This report presents a rare case of a TSH-oma in a frail patient with multiple comorbidities, highlighting diagnostic and therapeutic challenges.
Case Presentation
A 74-year-old Tunisian male with a history of well-controlled type 2 diabetes of 8 years, hypertension, stage 3 chronic kidney disease, iron deficiency anemia, global heart failure with preserved ejection fraction, and stage 4 peripheral artery disease presented with a 3-month history of asthenia and hand tremors. Biochemical analysis revealed severe hypocalcemia and hyperphosphatemia. Hormonal assays confirmed central hyperthyroidism with elevated TSH and FT4. There was no anterior pituitary deficiency. Pituitary MRI revealed a macroadenoma measuring 29x26 mm, with extension to sphenoid and cavernous sinuses, especially on the left, with filling of the suprasellar cisterns leading to a slight dilation of the lateral ventricles. Fundus examination revealed minimal diabetic retinopathy and dense bilateral cataract.
Discussion
The first line treatment for TSH-omas is transsphenoidal pituitary surgery, aimed at reducing thyroid hormone levels to prevent thyrotoxicosis and thyroid storm. However, due to the patient's multiple comorbidities and potential contra-indications to general anesthesia, medical management with somatostatin analogs was considered as an alternative. Early diagnosis and appropriate treatment are crucial to preventing complications.

Comparison of normetanephrine and metanephrine secretion in pheochromocytoma: clinical and radiological features

Mariam Mabrouk[1], Bchir Najla[1], Dorra Dorraelguiche[1], Yosra Abderrahim[1], Annam Benchhida[1], Chedia Zouaoui[1] & Haroun Ouertani[1]
[1]Military Hospital of Tunis, Endocrinology Department, Tunis, Tunisia

Introduction
Pheochromocytoma are neuroendocrine tumors originating from chromaffin cells of the adrenal medulla or extra-adrenal paraganglia. The aim of this study was to compare clinical and radiological characteristics of normetanephrine- and metanephrine secreting pheochromocytomas.
Subjects and Methods
This retrospective single-center study included 12 patients with confirmed pheochromocytoma followed up at the outpatient clinic of the endocrinology department in Tunis Military Hospital. Clinical and paraclinical data were extracted from patients' medical records. Patients were divided into two groups: Group 1 ($n = 6$) with normetanephrine-secreting tumors, defined as normetanephrine level more than 3 times the normal limit and Group 2 ($n = 4$) with metanephrine-secreting tumors, defined as metanephrine level more than 3 times the normal limit. Two mixed-secretion cases were excluded.
Results
The median age (IQR) at diagnosis was 45 (29 – 65) years in the first group and 58 (37 – 74) years in the second group ($P = 0.257$). Clinical presentation included paroxysmal hypertension (2 cases in each group), permanent hypertension (G1: 4 vs G2: 1), resistant hypertension (G1: 2 vs G2: 1) and Menard triade (G1: 4 vs G2: 3). No significant difference was noted in the two groups. Adrenal incidentaloma was the circumstance of discovery in all cases in group 1 and 3 cases in group 2. Median heart rate was 82 bpm (IQR:74 – 105) in group 1 and 76 (IQR:68 – 106) in group 2 ($P = 0.476$). Median blood pressure during crisis was 190/105 mmHg in group 1 ($P = 0.393$) and 180/100 in group 2 ($P = 0.629$). Complications were present in 3 cases in the first group and 2 cases in the second group. They included albuminuria (1 vs 2, $P = 0.524$), ventricular hypertrophy (1 case in each group), hypertensive retinopathy (2 vs 1, $P = 1.000$), haemorrhagic stroke and myocardial infarction in 1 case in group 2. Radiological findings showed a median size of 57 mm (IQR:48 – 68) in group 1 vs 50 mm (43 – 68) in group 2 ($P = 0.762$). Median washout was 28% (IQR:21 – 39) in group 1 and 45% in group 2 ($P = 0.610$). All normetanephrine tumors were heterogeneous, vs 3 (75%) of the other group. Left location of the tumor was more frequent in both groups. All patients had adrenalectomy. One patient had persistent hypertension postoperatively. However, the number of antihypertensive drugs decreased from 3 to 1.
Conclusion
This study found no significant differences between normetanephrine- and metanephrine-secreting pheochromocytomas. Due to the rarity of these tumors, further large-scale studies are needed to validate these findings.

Background
Molecular imaging is gaining importance in the localisation diagnostics of pituitary disease. However, the availability of tracers varies between different centres. The currently best evidence exists for the amino acid tracer ^{11}C-methionine (MET).^{18}F-fluoroethyl-tyrosine (FET) has been reported as a potential alternative to MET with broader availability. While ^{68}Ga-DOTATOC (DOTATOC) shows high uptake in the normal pituitary gland, data is limited regarding uptake in adenomas.
Methods
Here we report a 35-year-old patient with residual acromegaly after two endoscopic transsphenoidal surgeries who had intolerable side effects under medical therapy and underwent DOTATOC-PET, FET-PET and MET-PET. All scans were undertaken in line with published PET acquisition references for each tracer.
Results
MET-PET and DOTATOC-PET identified two distinct foci of increased tracer uptake. In the context of the anatomical imaging (pre- and post-op), the most intense left-sided focus was suspected to represent physiological uptake within normal gland and the right-sided focus to represent residual somatotroph tumour. In contrast, FET-PET did not clearly identify a discrete focus of intrasellar uptake and only showed physiological uptake in the cavernous sinuses. Four months after CyberKnife therapy targeting the suspected tumour in the right cavernous sinus – and limiting the radiation dose to the physiological pituitary gland to $\leq$20% of the maximum – the insulin-like growth factor I declined from 1.55 to 1.18 times the upper limit of normal. No new pituitary deficits were observed.
Conclusion
This case confirms a role for MET-PET in accurate localisation of residual tumour in acromegaly and is consistent with previously published studies. Although not matching the higher resolution of MET-PET, DOTATOC-PET facilitated similar clinical decision-making. In contrast, FET-PET did not offer any diagnostic benefit in this case.

Background
The causes of central diabetes insipidus (CDI) are often unclear at the time of diagnosis. The clinical presentation and typical brain MRI findings in CDI are not always specific to a particular cause.
Aims
This study aims to assess the prevalence of distinct brain MRI abnormalities in CDI patients and explore potential associations between these findings and the underlying etiology of CDI.
Methods
Data from 131 patients were analyzed, including 109 with CDI of various causes and 22 with Langerhans cell histiocytosis (LCH) without CDI, with disease onset between 0 and 17.99 years and a follow-up period of at least two years. A total of 1,355 brain MRIs were reviewed to identify specific MRI changes. The thickness of the proximal, middle, and distal segments of the pituitary stalk was measured at onset and six months later. Hormone deficiencies were also evaluated and correlated with MRI abnormalities.
Results
Extrasellar lesions were found in 16 of the 109 CDI patients (14.7%), with a significantly higher prevalence in LCH patients compared to those with neuro-oncological causes ($P = 0.004$) and genetic, malformative, or post-infectious causes ($P = 0.012$). However, the prevalence of extrasellar lesions did not significantly differ between LCH and idiopathic CDI. In LCH patients, extrasellar lesions were more common in those with CDI ($P = 0.024$). FLAIR hyperintensity of the tuber cinereum was noted in 8 CDI patients (7.3%), and this was more frequent in CDI patients with LCH than those with other etiologies ($P < 0.0001$), being absent in LCH patients without CDI. Hypothalamic involvement was significantly more common in CDI patients with neuro-oncological causes. A mismatch pattern was observed in 21 CDI patients (19.3%), more commonly seen in idiopathic CDI and CDI with LCH ($P < 0.0001$). No significant change in pituitary stalk thickness was observed between the initial and six-month follow-up assessments in any patient group.
Conclusions
FLAIR hyperintensity of the tuber cinereum was more frequently seen in patients with LCH, suggesting it could be a specific marker for LCH. Extrasellar lesions were more common in LCH patients compared to those with other CDI causes and were more frequent than in idiopathic CDI, highlighting their potential as an early indicator of LCH.

JOINT3439

A rare association between pituicytoma and cushing's syndrome

Alessandro Risio[1], Vittoria Favero[1,2], Giacomo Fabio Antonio Grifoni[1], Erika Grossrubatscher[2], Andrea Saladino[3], Renato Cesare Cozzi[2] & Iacopo Chiodini[1,2]
[1]Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [2]ASST Grande Ospedale Metropolitano Niguarda, Unit of Endocrinology, Milan, Italy; [3]IRCCS Foundation Carlo Besta Neurological Institute, Milan, Italy

Pituicytoma is a rare, low-grade spindle-cell astrocytic tumor of the posterior pituitary or its stalk, classified as a WHO grade I central nervous system tumor. It's typically located in the sellar or suprasellar region and is often misdiagnosed as other sellar lesions such as pituitary adenoma or craniopharyngioma. Clinically, a pituicytoma presents with signs of mass effect and hypopituitarism due to compression of the pituitary gland. It's also common to have hyperprolactinemia because of stalk effect. Additionally, diabetes insipidus was described. While less than 200 cases of pituicytoma have been reported in the literature, endocrine hyperfunction, particularly Cushing's disease and acromegaly, is a rare occurrence. Here, we report two cases of pituicytoma associated with Cushing's syndrome. **Case 1** A 38-year-old woman presented with hirsutism mostly on the face and the abdomen. Eleven years earlier, she had undergone endocrinological evaluation for hirsutism, acne, and a 10-kg weight gain. In 2023 tests showed hypercortisolism: urinary free cortisol (UFC) 1.12 ULN, ACTH 56 pg/ml, cortisol after 1 mg dexamethasone suppression test (F-1mgDST) 6.58 µg/dl. 8-mg overnight dexamethasone suppression test and desmopressin stimulation test were suggestive for Cushing's disease. MRI identified a 3-mm hypointense lesion on T1-weighted sequences in the right anterolateral pituitary, suggestive for pituitary microadenoma. She underwent surgery, achieved disease remission and developed secondary adrenal insufficiency. Histology revealed that the lesion was a pituicytoma. **Case 2** A 40-year-old woman complained of with

symptoms including hirsutism, buffalo hump, easy bruising, hypertension, and weight gain over the past two years. Laboratory tests confirmed a diagnosis of overt Cushing's disease (UFC 5.47 ULN, ACTH 53 pg/ml, F-1mgDST 17.4 μg/dl,) and MRI showed a 4-mm microadenoma in the left pituitary. The desmopressin test result was consistent with Cushing's disease (ACTH increase of 115% over baseline). She underwent transsphenoidal surgery, achieved clinical remission and developed adrenal insufficiency. Histological features were indicative of pituicytoma.

Discussion

About 15 cases of pituitary tumors associated with Cushing's syndrome have been documented so far. Since pituicytomas are classified as gliomas, hormone secretion is considered unusual. The observed ACTH production could potentially result from an undetected microadenoma, such as a Crooke's cell adenoma, or from paracrine signaling that stimulates the proliferation of anterior pituitary cells. This coexistence might not be coincidental but could suggest an unknown pathophysiological connection or a shared progenitor cell origin. Performing histological analysis with ACTH immunostaining could help to identify hidden lesions and provide insight into the underlying mechanisms.

Introduction

First-generation somatostatin analogues (SSa) are first-line medical therapy for acromegaly. They are generally well-tolerated but during long-term therapy, cholelithiasis, which may require cholecystectomy (CH-Tx), and other hepato-biliary-pancreatic adverse events can occur. This study aimed at evaluating the prevalence of hepato-biliary/pancreatic adverse events during SSa treatment, and at identifying factors influencing their development.

Methods

371 acromegaly patients (223F, age 63 ± 0.77yrs) were evaluated retrospectively, collecting clinical/biochemical/instrumental data at diagnosis (T0), at SSa therapy start (T1) and at last follow-up visit (120 ± 6.54 months). The occurrence of CH-Tx, cholecystitis (CH), mild hypertransaminasemia (<5xULN) or severe hypertransaminasemia (>5xULN) (HT), mild (<5xULN) or severe (>5xULN) hyperlipaemia/hyperamylasemia (HH) during SSa treatment, and their relationship with clinical and biochemical features at T0/T1 have been investigated.

Results

61 patients (16.4%)(40F) underwent CH-Tx, 14 (3.8%) developed CH, 8 (2.2%) severe HH and 19 (5.12%) mild HH, 4 (1.1%) severe HT and 24 (6.47%) mild HT, without significant differences in terms of gender or after patients' stratification by age >/< 50yrs. Chi-square test revealed that patients undergoing CH-TX or CH had a higher prevalence of biliary lithiasis at T1 ($P = 0.002$, $P = 0.005$, respectively), while mild hypertransaminasemia was associated with higher frequency of diabetes mellitus at T1 ($P = 0.019$). Cholecystectomy was associated to higher age and biliary sand at T1 ($P = 0.018$; $P = 0.016$, respectively), according to multivariate analysis, and with ursodeoxycholic acid (UDA) treatment at T1 in univariate analysis ($P = 0.035$). Cholecystitis was associated with UDA treatment ($P = 0.003$) and elevated GH-levels at T1 ($P = 0.044$) in univariate and multivariate analyses, respectively. Severe HH was associated with UDA treatment in both univariate ($P = 0.003$) and multivariate analyses ($P = 0.026$). The occurrence of mild or severe HT was associated, in univariate analysis, with UDA treatment ($P = 0.056$) and biliary lithiasis at T1 ($P = 0.055$), respectively. When considering hepato-biliary-pancreatic adverse events overall, they were found to be significantly associated to age, biliary lithiasis, and biliary sand at T1 in both univariate ($P = 0.013$, $P = 0.006$, $P = 0.010$, respectively) and multivariate analyses ($P = 0.044$, $P = 0.029$, $P = 0.028$, respectively).

ConclusionS

Hepato-biliary/pancreatic adverse events during long-term treatment with SSa are not infrequent, and overall influenced by age, cholelithiasis and biliary sand. The relevance of preexisting hepato-biliary issues in their occurrence is also demonstrated by the evidence of the association with UDA treatment.

JOINT2598

Clinico-radiological correlation analysis of a cohort of 50 children with pituitary stalk interruption syndrome

Joanna Chrzanowska[1], Aleksandra Bodetko[1], Joanna Bladowska[2], Jagoda Jacków-Nowicka[3] & Robert Śmigiel[1]

[1]Department and Clinic of Paediatrics, Endocrinology, Diabetology and Metabolic Diseases Medical University, 50-368 Wroclaw, Poland, Wrocław, Poland; [2]Wroclaw University of Science and Technology, Faculty of Medicine, Department of Medical Radiology and Imaging Diagnostics, Wrocław, Poland; [3]Department and Clinic of Radiology, Medical University, 50-368 Wroclaw, Poland, Wrocław, Poland

Pituitary stalk interruption syndrome (PSIS) is diagnosed on the basis of clinical manifestation and the characteristic picture of pituitary gland on MRI. PSIS may represent an isolated morphological abnormality or may be accompanied by other structural defects of the midline of the brain. In terms of endocrine evaluation, it is characterised by a wide spectrum ranging from the absence of significant endocrine abnormalities to combined pituitary hormone deficiency (CPHD). In patients with PSIS, it is difficult to predict when hypopituitarism (isolated or CPHD) will become apparent.

The aim of this study was to characterize the correlation between the pituitary hormonal pattern and the MRI features in 50 children with PSIS.

Results

Out of 50 subjects, 30 (60%) were diagnosed with CPHD, while 18 (36%) with isolated GHD. In 1 boy with vasopressin deficiency, endocrine function of the anterior pituitary was normal (2%), while in 1 girl (2%) who remains under the neurological care due to cerebellar vermis dysplasia, no endocrine abnormalities were found. Five patients out of 50 (10%) were diagnosed with arginine vasopressin deficiency. GHD was diagnosed in 47 children (94%). It should be noted that one patient presenting with IGF-1 and GH below normal (0.05 ng/ml) has achieved age-appropriate growth (90-97c) was not classified as a child with GHD. MRI examination showed anterior pituitary hypoplasia in 45/50 children (90%), none of them presented with aplasia. Agenesis of the pituitary stalk was observed in 13/50 patients (26%) and hypoplastic pituitary stalk in 36/50 patients (72%). The ectopic posterior pituitary lobe was diagnosed in 45/50 subjects (90%), while in 5 patients the posterior lobe was not visible. Septo-optic dysplasia was diagnosed in 21/50 patients (42%): 3/3 criteria – 9 children, 2/3 criteria -12 children. In the group with pituitary stalk agenesis, isolated GHD was diagnosed in 15.4% patients, whereas CPHD was presented in 84.6% cases. In the group with pituitary stalk hypoplasia isolated GHD or no abnormalities in anterior pituitary were diagnosed in 47% patients whereas CPHD was observed in 53% cases. In 15/16 children (94%) with optic nerve hypoplasia were found to have CPHD. Diabetes insipidius was diagnosed exclusively in the 5 patients in whom the posterior pituitary lobe was not visualised 1. Picture of pituitary stalk agenesis and optic nerve hypoplasia in MRI may determine the severity of endocrine disorders of the anterior pituitary. 2. The absence of the posterior pituitary correlates with the development of diabetes insipidus.

Cabergoline therapy in adolescent cushing's disease: hypercortisolism improvement with persistent tumor

Mohamed Samir Merad[1] & Houssam Baghous[1]

[1]Oran 1 Ahmed Ben Bella Medical University, Endocrinology and Diabetology departement -Larribere Clinic – University Hospital Dr Benzerdjeb, Oran, Algeria

Background
Cushing's disease is the most common etiological agent of endogenous hypercorticism. Furthermore, 90% of corticotropic adenomas are microadenomas. While surgery is typically the go-to treatment, there are situations where medication can play a key role in managing the condition.
Case report
We present the case of a 17-year-old patient referred for evaluation of hypercortisolism. The clinical examination revealed overt signs of Cushing's syndrome, with a predominance of catabolic manifestations: extensive, horizontal, purple stretch marks on the abdomen, axillae, and proximal limbs, as well as muscle atrophy in the girdle regions. The 24-hour urinary free cortisol (UFC) level was 7 times the upper limit of normal. A 2-day low-dose dexamethasone suppression test and an elevated ACTH level of 11.32 pmol/l(> 4.4 pmol/l)confirmed the diagnosis of ACTH-dependent Cushing's syndrome. A high-dose suppression test further supported the diagnosis of Cushing's disease. A pituitary MRI identified a 1.8 mm microadenoma. Since ketoconazole was not available, we started him on Cabergoline, 0.5 mg once a week, and referred him to neurosurgery for further evaluation. After 18 months, the patient had not undergone surgical intervention. Remarkably, clinical follow-up demonstrated significant regression of hypercortisolism symptoms, with normalization of 24-hour UFC levels. Repeat hypothalamic-pituitary MRI showed no change in the size of the microadenoma.
Conclusion
Depending on the series, the efficacy of cabergoline ranges from 25 to 40%. In certain cases of Cushing's disease, particularly when accompanied by a pituitary picoadenoma, it may still be a useful treatment option.

Bilateral achilles tendon rupture: a rare presentation of cushing's disease

Patricia Ferreira[1,2], João Menino[1,2], Ana Rita Leite[1,2], Inês Meira[1,2], Joana Queirós[1] & Jorge Pedro[1,2]
[1]Serviço de Endocrinologia, Diabetes e Metabolismo, ULS São João, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto, Porto, Portugal

Introduction
Cushing's disease, an endocrine disorder caused by ACTH-secreting pituitary adenomas, encompasses a wide spectrum of systemic complications. While metabolic, cardiovascular, and musculoskeletal alterations are common manifestations, tendon ruptures are exceptionally rare as an initial presentation. These ruptures reflect the profound impact of chronic hypercortisolism on connective tissue integrity, highlighting the need for vigilance in diagnosing atypical presentations of this condition.
Case Report
A 40-year-old woman presented to the endocrinology consultation with a two-year history of amenorrhea and infertility following the discontinuation of oral contraceptives, accompanied by progressive hirsutism, weight gain, easy bruising, and proximal muscle weakness. Additionally, she had a bilateral Achilles tendon rupture, with no preceding trauma or excessive physical exertion. Her medical history was relevant for hypertension and prediabetes, with no medication. On presentation to our clinic, she reported proximal myopathy and had a BMI of 21.1kg/m^2 with no evident signs of Cushing's disease. Biochemical evaluation revealed elevated 24-hour urinary free cortisol (138 nmol/L; reference: 11.5–102), a lack of suppression on a low-dose dexamethasone suppression test (post-dexamethasone cortisol: 7.2 µg/dl), and elevated salivary cortisol (0.4 µg/dl; reference: <0.27). ACTH levels were elevated at 40 pg/ml, suggesting an ACTH-dependent cause. Magnetic resonance imaging identified an 11 mm right-sided pituitary macroadenoma. The patient was started on metyrapone 500mg/day while awaiting surgery. She was submitted to an uneventful endoscopic transsphenoidal resection, which confirmed a corticotroph pituitary neuroendocrine tumor with positive ACTH immunostaining. Postoperatively, the patient demonstrated significant clinical improvement, with resolution of muscle weakness and normalization of cortisol levels on follow-up.
Discussion
This case highlights the broad and atypical spectrum of presentations in Cushing's disease. Bilateral Achilles tendon rupture is an uncommon yet severe complication attributed to the detrimental effects of chronic hypercortisolism on connective tissue. In fact, cortisol excess disrupts collagen synthesis by impairing fibroblast function and increasing matrix metalloproteinase activity, which degrades the extracellular matrix. These effects weaken tendons and predispose them to rupture, even in the absence of significant trauma. Proximal myopathy further exacerbates tendon vulnerability by altering biomechanical stress patterns. This case underscores the importance of recognizing atypical manifestations of Cushing's disease, such as bilateral tendon rupture, and highlights the need for multidisciplinary management to optimize patient outcomes. A high index of suspicion and thorough clinical evaluation are essential for early diagnosis and treatment of this condition.

Giant prolactinoma in adult males

Mouna Elleuch[1], Yassmine Abdelkafi[1], Zaineb Fourati[1], Mohamed Khairi Arous[1], Yesmine Elloumi[1], Mouna Mnif[1], Dhoha Ben Salah[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Pituitary adenomas represent 15% of brain tumors, with prolactinomas accounting for 40% of these. Prolactinomas are classified into micro, macro, and giant prolactinomas based on size. Macroprolactinomas and giant prolactinomas are more common in men, often without specific clinical signs, leading to delayed diagnosis.
Methods
We conducted a descriptive and analytical study of 36 men followed at the Endocrinology and Diabetology Department of Hedi Chaker University Hospital in Sfax for prolactin-secreting adenomas. We specifically investigated the characteristics of giant prolactinomas, defined as those with a size greater than 4 cm.
Results
Giant prolactinomas were observed in 11 patients (30.6%). The mean age at diagnosis was 43.6 $\pm$ 15.1 years, with extremes ranging from 19 to 75 years. The primary clinical presentations included headaches (86.1%), visual disturbances (69.4%), and sexual dysfunction (47.2%). Hypopituitarism was common, with gonadotropic insufficiency in 63.9% of cases. Imaging revealed significant tumor extensions into suprasellar and lateral regions. The mean prolactin level was 18,662 $\pm$ 52,817 ng/ml. Dopamine agonists were the first-line treatment, with surgery reserved for resistant or complicated cases. A positive correlation was observed between tumor size and prolactin levels (rho $=$ 0.658, $P < 0.001$). Additionally, tumor size was associated with increased risk of hypopituitarism, particularly gonadotropic and thyrotropic insufficiencies. However, no significant correlation was found between tumor size and metabolic parameters such as BMI or waist circumference.
Conclusion
Giant prolactinomas in men present challenges due to their size and nonspecific symptoms, often resulting in delayed diagnosis. Early identification and multidisciplinary management are essential to prevent complications related to vision, endocrine dysfunction, and quality of life.

When hormones disagree: a case of elevated ACTH with normal cortisol and suspected macro-ACTH

Nora Harutyunyan[1], Hasmik Khachatryan[1,2], Yelena Aghajanova[2,3], Lusine Vardanyan[4] & Armine Khroyan[3,4]
[1]Yerevan State Medical University, Yerevan, Armenia; [2]Muratsan University Hospital Complex, Yerevan, Armenia; [3]Yerevan State Medical University, Endocrinology, Yerevan, Armenia; [4]Armenian-American Wellness Center, Yerevan, Armenia

Background
Pituitary adenomas are common intracranial neoplasms, often presenting with symptoms related to hormone overproduction or mass effect. Cushing's disease results from adrenocorticotropic hormone (ACTH) secreting pituitary adenomas, typically leading to cortisol overproduction. However, some patients exhibit elevated ACTH levels with normal cortisol and an atypical clinical presentation, complicating the diagnosis. In rare cases, this discrepancy may be due to macro-

ACTH, a condition in which pituitary corticotroph cells produce large, biologically inactive ACTH molecules. These molecules have prolonged circulation, leading to falsely elevated ACTH readings without cortisol excess. We present a case of a 34-year-old male with elevated ACTH and normal cortisol levels, raising suspicion for macro-ACTH or a similar rare condition.
Case report
A 34-year-old male was referred by a neurologist with complaints of fatigue, lightheadedness, and mental fog. Neurological examination revealed no meningeal or focal neurological signs. Physical examination was unremarkable, with no signs of hypercortisolism or hypocortisolism. Contrast-enhanced MRI revealed a 15×26×18 mm pituitary macroadenoma with intrasellar, infrasellar, and laterosellar extension, sparing the optic chiasm. Hormonal tests showed elevated ACTH- 215.1 pg/ml (7.2–63.6 pg/ml) but normal morning cortisol levels - 417.3 nmol/l(133–537 nmol/L). Salivary cortisol and 24-hour urinary free cortisol were normal (18.2 nmol/land 42 mg/day, respectively). Levels of the remaining pituitary hormones were within normal limits. Following the low-dose dexamethasone suppression test, cortisol levels were appropriately suppressed, but ACTH remained persistently elevated. The discordance between elevated ACTH and normal cortisol, without clinical signs of cortisol excess, raised suspicion for macro-ACTH secreting adenoma, which releases large, biologically inactive ACTH molecules. However, due to the unavailability of specialized laboratory tests, a definitive diagnosis could not be confirmed. The patient was referred for neurosurgical assessment and management is ongoing.
Discussion
This case highlights the diagnostic challenges in ACTH-secreting pituitary adenomas with atypical presentations. Macro-ACTH, though rare, should be considered when ACTH is elevated despite normal cortisol levels and the absence of clinical signs of cortisol dysregulation.
Conclusions
When laboratory and clinical findings are inconsistent, macrohormone-related interference, such as macro-ACTH, should be considered. Although confirmatory testing was unavailable in this case, recognizing this possibility helped avoid unnecessary treatments. In cases where specialized laboratory tests are unavailable, clinicians should rely on a combination of clinical judgment, biochemical patterns, and response to treatment to guide management. While routine testing for macrohormones is not recommended, awareness of their impact can prevent unnecessary interventions and improve patient outcomes.

Thyrotropin deficiency and transient central adrenal insufficiency with anterior pituitary hypoplasia in an infant with neurofibromatosis–noonan syndrome

Cheng Guang Gan[1] & Nisah Abdullah[1]
[1]Hospital Sultanah Aminah, Paediatric, Johor Bahru, Malaysia

Neurofibromatosis–Noonan syndrome (NFNS) is a rare genetic entity associated with the clinical phenotype of two conditions: neurofibromatosis type 1 syndrome (NF1) and Noonan syndrome (NS). Sellar and suprasellar disorders with or without pituitary hormone deficiencies are not commonly associated with both NF1 and NS. However, there are reported cases of such presentations in both adults and children with NF1 or NS. To-date, there is only a case of 13-year-old girl with NFNS reported to have isolated growth hormone deficiency with pituitary hypoplasia. We describe the case of an 1-year-old boy with clinical NFNS, anterior pituitary hypoplasia, transient central adrenal insufficiency (CAI) and thyrotropin deficiency (TSHD) presented at 9 months old with failure to thrive (both height and weight < 3rd centile), severe airway obstruction required tracheostomy secondary to right neck plexiform neurofibroma and recurrent hypoglycaemia. The diagnosis of TSHD was established with inappropriate low normal TSH and low FT4. CAI was diagnosed with a hypoglycaemic (glucose 2.9 mmol/l)critical sampling showing an inappropriate low cortisol level of 155 nmol/land an undetectable early morning ACTH levels. He was treated with hydrocortisone and levo-thyroxine replacement at that time. A Synacthen test off hydrocortisone showed normal cortisol response (Peak cortisol 590.6 nmol/l)and normal ACTH of 6.78pmol/lat 11-month-old followed by a normal 16 hours diagnostic fasting test profile. His other pituitary profile revealed normal IGF-1, prolactin and pre-pubertal levels of gonadotropins. The diagnosis of NFNS was made as he fulfilled the diagnostic criteria of NF1 (> 6 café-au-lait spots (>5 mm) with one plexiform neurofibroma) and the Van der Burgt criteria of NS. Clinically, he has short stature, frontal bossing, café-au-lait spots and pectus excavatum. His pituitary MRI findings revealed a small anterior pituitary gland. In summary, we presented a 1-year-old boy with NFNS and anterior pituitary hypoplasia. The case is the youngest NFNS patient to have pituitary hormone deficiencies with abnormal pituitary imaging in the literature. The findings in this patient show that seller or suprasellar anomalies with pituitary hormone deficiency can be a feature of NFNS as early as infancy. Therefore, there should be a high index of suspicion of pituitary hormone deficiency in children with NFNS.

Case Report: SIAD caused by LGI-1 antibody encephalitis

Laura Ryan[1], Nur Sakinah Zulkifli[1] & John McManus[1]
[1]University Hospital Limerick, Limerick, Ireland

Antibodies against LGI-1 (Leucine-rich glioma-inactivated 1) were first described in 2010[1]. LGI-1 antibody encephalitis is rare with an incidence of 0.83 per million persons per year[2]. It is more common in men and has a median age of onset of 65 years. It is characterised by features of limbic encephalitis with frequent focal seizures and associated hyponatraemia is common. We present the case of a 73yo man who presented to the emergency department with a transient episode of expressive aphasia and numbness of his right hand that lasted approximately 15 minutes. Background medical history included diverticular disease, hiatus hernia, hypercholesterolaemia and benign prostatic hypertrophy. He was not taking any regular medications at the time of admission. He had a good functional baseline and was independent in all activities of daily living. Examination was unremarkable and he was noted to be clinically euvolaemic. CT brain and subsequent MRI brain did not show any acute abnormalities. Serum sodium on admission was 126mmol/lwith serum osmolality 257mmol/kg and urine sodium 71mmol/lwith urine osmolality 552mmol/kg, in keeping with syndrome of inappropriate antidiuresis (SIAD). Thyroid function tests were normal and random cortisol was 263nmol/lso he underwent a short synacthen test which had a 30 minute cortisol value of 752nmol/L. CT thorax, abdomen and pelvis did not show any evidence of malignancy. Sodium improved following fluid restriction and he was discharged home. He represented 2 weeks later with a generalised tonic clonic seizure. On further questioning his wife recounted fluctuating memory over the last few months, sleep disturbance and a change in mood. He was commenced on levetiracetam and had investigations for autoimmune encephalitis. A serum sample detected the presence of LGI-1 antibodies. He completed a course of intravenous immunoglobulin followed by plasma exchange. Sodium increased to 135mmol/land he has not had any further seizure events. The diagnosis of LGI-1 antibody encephalitis provided a unifying diagnosis in this case. In cases of SIAD it is important to consider alternative aetiologies where a cause is not immediately obvious and LGI-1 antibody encephalitis is an important diagnosis to consider in older adults presenting with SIAD, neurological and cognitive symptoms.

Sheehan's syndrome revealed by profound hypothyoidism: a case report

Amal Riad[1], Kaoutar Rifai[1], Iraqi Hinde[1] & Mohamed Elhassan Gharbi[1]
[1]Ibn Sina Institution, Rabat, Morocco

Introduction
Sheehan's syndrome is a rare but potentially serious complication of the post-partum period. It involves ischaemic necrosis of the anterior pituitary gland secondary to a sudden and/or prolonged state of shock during a delivery haemorrhage.
Case report
A 59-year-old patient with a history of iron deficiency anemia and dyslipidemia over the past 2 years. She was consulted for major asthenia associated with chilliness and chronic constipation. Examination revealed bradycardia and a thyroid work-up showed TSH at 0.7 U/lwith low FT4 <0.42 ng/dl. Questioning revealed a history of haemorrhagic childbirth 15 years ago with absence of lactation and seondary amenorrhoea. An 8-hour cortisol test showed 23 ng/ml and hypogonadotropic hypogonadism. The MRI showed an arachnoidocele. The

patient was substituted.
Discussion
The incidence of this condition is underestimated because diagnosis is often late, made more than ten years after the obstetric event in 50% of cases. Furthermore, it is estimated that around 25% of women who die within the first 30 days post-partum have developed clinical signs of pituitary necrosis. There is an abundance of literature concerning the discovery of Sheehan's syndrome at a distance from childbirth. However, there have been very few reports of this syndrome being diagnosed in the immediate post-partum period.
Conclusion
Postpartum pituitary necrosis is a difficult diagnosis in the acute phase, often unrecognised. Careful questioning can contribute enormously to the diagnosis and early management of our patients.

Rheumatological manifestations of acromegaly: a report of 78 cases
Mashal Rajaa[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital of Casablanca, Morocco, Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II – Casablanca-Morocco, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Departement, Casablanca, Morocco

Introduction
Acromegaly can manifest itself through very frequent degenerative rheumatological complications responsible for long-term after-effects.
The objective
To describe the rheumatological manifestations of acromegaly.
Patients and Methods
This is an retrospective study of 78 cases of acromegaly followed up in the endocrinology department of Ibn Rochd University Hospital from 2005 to 2024. Rheumatological complications were noted at diagnosis or during follow-up.
Results
The mean age was 45 years (18–72), the sex ratio: 0.33, the mean duration of the disease was 8 and a half years. The mean IGF-1 level was 582 ng/ml or 2.62 times the normal. The rheumatological manifestations like peripheral articular manifestations were dominated by knee pain in 55 patients (42.9%). Diffuse arthralgia was present in 5 acromegalic patients (3.9%), elbow pain in 7 patients (5.46%) and shoulder arthralgia in 3 patients (2.34%). Dorso-lumbar back pain, was present in 36 patients (28.08%) associated with unilateral sciatica in two patients. Carpal tunnel syndrome, were reported in 5 patients (3.9%). The phosphocalcic profile was without abnormality. The mean vitamin D level was 14.3 ng/dl. Bone densitometry showed osteopenia in 5 patients, osteoporosis in one patient and was normal in the rest of the patients.
Conclusion
The rheumatological manifestations linked to acromegaly include peripheral, axial and canal joint involvement, hence the importance of looking for them at the time of diagnosis and during follow-up in order to limit their impact on the functional prognosis of patients.

Genotype-negative MEN 1 - limitations of genetic testing
Alexandra-Irina Gidei[1], Miruna-Alicia Marin[1], Anca Andrei[1], Andreea Pena[1], Alexandra Mohora[1], Ramona Dobre[1,2], Iulia Burcea[1,2] & Catalina Poiana[1,2]
[1]National Institute of Endocrinology C.I.Parhon, Bucharest, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a rare autosomal dominant disorder caused by germline mutations of the tumor suppressor MEN1 gene. The most common manifestations include: primary hyperparathyroidism (PHPT), pituitary adenomas (PA) and gastroenteropancreatic neuroendocrine tumors (GEP-NET). The classical Sanger monogenic sequencing of the MEN1 gene is the gold standard for the genetic diagnosis. In 10-30 % of MEN1 patients, no mutation is identified through this technique and those are defined as genotype-negative (GN)-MEN1. GN-MEN1 typically has a more favorable clinical course than the genotype-positive MEN1. We herein report two cases of genotype-negative MEN1.
Case Presentation
The first patient, a 60-years-old woman with no family history of MEN1, presented with classic features of MEN1: primary hyperparathyroidism caused by double parathyroid adenomas, for which she underwent surgical excision of the left parathyroid glands, a non-functional pituitary microadenoma and a well-differentiated NET of the ileum, with hepatic and lymph node metastases, for which she was admitted to surgery. She is currently undergoing treatment with lanreotide. She associates non-functional left adrenal hyperplasia and a history of papillary thyroid carcinoma for which she underwent total thyroidectomy and radioactive iodine therapy. The Sanger sequencing of the MEN1 gene revealed no pathogenic variant. The second patient is a 33-years-old woman with two manifestations suggestive for MEN1: double pituitary microadenomas with prolactin secretion and primary hyperparathyroidism with no ecographic localisation, for which she will undergo parathyroid scintigraphy. There is no family history of MEN1. She associates non-functional bilateral andrenal hyperplasia. No MEN1 gene mutations have been identified by the Sanger sequencing.
Conclusion
Sanger sequencing of the MEN1 gene is the gold standard method for accurate detection of single nucleotide variants and small deletions/insertions, but it cannot identify gross gene deletions/insertions. Multiple ligation-dependent probe amplification (MLPA), a multiplex PCR technique that is able to detect large MEN1 coding region deletions/duplications should be considered in MEN1 index cases with negative MEN1 sequencing test. In addition, germline mutations in other genes that may cause a MEN1-like disorder, such as the AIP gene and the cyclin-dependent kinase inhibitor genes CDKN1A, CDKN2C, CDKN2B and CDKN1B, should be considered for further investigations. In conclusion, all methods of genetic testing have their limits, but a high clinical suspicion should be reason enough for more thorough research.

JOINT2707
A clinical case of infective endocarditis in a patient with acromegaly: impact on biochemical markers
Zalina Gabaraeva [1], Mariia Berlovich[1], Ekaterina Pigarova[1], Larisa Dzeranova[1], Elena Przhiyalkovskaya[1] & Raisa Bukatsello[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Acromegaly is a neuroendocrine disorder characterized by excessive growth hormone (GH) secretion, which exerts anabolic effects on various organs and tissues. Through direct action or indirectly via insulin-like growth factor-1 (IGF-1), GH can contribute to endothelial dysfunction, which is closely linked to cardiovascular complications, including cardiac pathology.
Clinical Case
A 54-year-old patient with acromegaly, who had undergone transnasal transsphenoidal pituitary adenoma resection on October 2019, was admitted to the Endocrinology Research Centre for remission assessment. Notably, two months prior to hospitalization, the patient was diagnosed with infectious spondylodiscitis of unspecified etiology, presenting with persistent fever and back pain. Spinal MRI confirmed spondylodiscitis at the Th6-7, Th9-11, and L3-5 levels. Despite antibacterial therapy, fever persisted. Rheumatological evaluation ruled out HLA-B27-associated spondylodiscitis, and NSAID therapy yielded no improvement. In the neuroendocrinology department, laboratory tests revealed elevated inflammatory markers: ESR 62 mm/h, ferritin 316.1 ng/ml, and CRP 272 mg/l,while procalcitonin remained within normal limits. Given the suspicion of hematogenous infection, transthoracic echocardiography suggested vegetations on the anterior mitral valve leaflet. Transesophageal echocardiography confirmed the presence of vegetations and severe mitral regurgitation. Blood cultures identified *Enterococcus faecalis*, and targeted antibiotic therapy with linezolid was initiated for two months, resulting in clinical improvement and subsequent mitral valve replacement. To assess acromegaly activity, IGF-1 levels were measured at 179.2 ng/ml (reference range: 104–230), while GH was slightly elevated at 6.79 ng/ml (0.4–3.6). However, the presence of an active infection complicated result interpretation. An oral glucose tolerance test (OGTT) for GH suppression was deemed unreliable due to the high likelihood of false-positive results. Brain MRI with contrast enhancement revealed residual adenomatous tissue, no ophthalmological signs of optic-chiasmal syndrome were noted at perimetry. Upon resolution of the inflammatory process, IGF-1 levels increased to 276 ng/ml, with persistent GH elevation and lack of suppression during OGTT. Consequently, octreotide therapy was initiated.

Conclusions
Acute inflammatory processes can significantly impact the interpretation of biochemical markers in acromegaly. Therefore, dynamic monitoring is essential to ensure accurate assessment and timely treatment adjustments.

Home capillary monitoring of sodium in a patient with adipsic diabetes insipidus

Ana Ortolá Buigues[1,2], Emilia Gomez Hoyos[1,2], Esther Delgado Garcia[1,2], Gonzalo Díaz Soto[1,2], Rebeca Jiménez Sahagún[1,2], Paloma Pérez López[1,2], María del Puerto Bernoy González[1,2], María Ángeles Castro Lozano[1,2] & Daniel de Luis Román[1,2]
[1]Hospital Clínico Universitario Valladolid, Valladolid, Spain; [2]Instituto Investigación Endocrinología y Nutrición. Facultad de Medicina., Valladolid, Spain

Introduction
Adipsic diabetes insipidus (ADI) is a rare variant of central diabetes insipidus, characterized by hypotonic polyuria due to arginine-vasopressin deficiency and failure to generate the sensation of thirst in response to hypernatremia secondary to hypothalamic osmoreceptors damage. This predisposes to the development of significant hypernatremia, so its management is complex and requires strict water balance control and treatment with desmopressin.
Clinical case
23-year-old male with neurofibromatosis type 1 and suprachiasmatic pilocytic astrocytoma treated with surgery, chemotherapy and proton therapy. After his last surgery in January 2021, he was diagnosed with ADI, panhypopituitarism and hypothalamic syndrome. For the treatment of ADI, he required high doses of desmopressin (minimum 600 mg/24 hours orally) and instructions were given to family members for its adjustment, as well as for the fluid intake control (minimum 2 liters/24 hours). He had basal natremias between 142 and 150 mmol/l,with frequent episodes of hypernatremia (around 1 to 4 per month) without trigger, up to >160 mmol/l,which were very difficult to control due to multiple factors (adipsia, neurological deterioration, refusal to eat, inability to record diuresis, …). For a period of less than 2 years, he required regular analytical measurements (at least 1 to 2 per month), several Home Hospitalization Unit visits for the administration of intravenous hypotonic solution, and as a last option, visits to the Emergency Department. In addition, he had 2 hospital admissions for this reason. In May 2023, a portable home blood analyzer (EPOC blood analysis system) was provided, properly validated for the determination of capillary sodium, and already used in pediatric ADI patients. Family members began to perform 1 or 2 capillary sodium measurements per week or when symptoms suggested hypernatremia, and instructions for adjusting desmopressin and water intake were reviewed. Given the earlier detection of elevated natremia, to date the patient has not required Home Hospitalization Unit assistance nor has he gone to the Emergency Department again for this sole reason, and switched to having lab tests only every 3 months. In addition, and also importantly, the quality of life of the patient and their relatives improved significantly.
Conclusion
Home capillary monitoring of natremia is an appropriate and cost-effective therapeutic measure for the treatment of ADI in both children and adults. For its proper use, it requires structured education for the patient and/or family members to adjust the treatment based on the results of capillary natremia.

Is the coexistence of acromegaly with primary empty sella syndrome rare?

Nagihan Bestepe[1], Feride Pinar Altay[1], Berna Ogmen[2], İzzet Selcuk Parlak[3], Didem Özdemir[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Türkiye; [3]Ankara Bilkent City Hospital, Radiology, Ankara, Türkiye

Objective
The association between growth hormone (GH)- secreting pituitary adenomas and primary empty sella (ES) has been reported mostly in case reports and is thought to be rare. In this study aimed to evaluate the coexistence of primary ES in newly diagnosed acromegaly and to investigate the effect of the presence of ES on the clinical and laboratory parameters of acromegaly.
Methods
Fifty-two patients with GH-producing pituitary adenomas who were followed up in our clinic between February 2017 and June 2024 and whose pituitary magnetic resonance imaging (MRI) was available at the time of diagnosis were analyzed retrospectively. Pituitary magnetic resonance imaging (MRI), computed tomography (CT) imaging, and pituitary function tests were evaluated. ES was defined as the pituitary gland and adenoma occupying less than 50% of the sella turcica on midsagittal magnetic resonance (MR) imaging. Demographic data, pituitary adenoma size, hormonal profile and postoperative pathologies of the patients were examined.
Results
Of 52 patients with acromegaly due to GH-producing pituitary adenomas, 27 (51.9%) were female and 25 (48.1%) were male (age range 21-73 years). Empty sella was detected in 8 (15.4%) patients and 2 had complete and 6 had partial empty sella. No ectopic adenoma cases were found in acromegaly patients with empty sella. No significant difference was found in preoperative pituitary hormone levels in patients with and without ES. Postoperative GH and insulin-like growth factor 1 (IGF-1) levels decreased in all patients.
Conclusion
This study showed that newly diagnosed acromegaly and primary ES coexisted in 15.4%. Acromegaly and ES coexisted more frequently than expected. The pathophysiology of this coexistence may be due to soft and hard tissue changes and serebrospinal fluid pressure changes that develop with the paracrine effect of GH during abundant GH production. The association between GH-producing adenomas and ES is not rare, but the underlying mechanism is not yet clear and requires further study.

A case of hypophysitis successfully treated by corticotherapy: a diagnostic challenge with germinoma in a 5-year-old chil

Sakina Kherra[1], Sihem Bellouti, Sifour Latifa[1], Chikh Amina[1], Madina Elogbi[1] & Zeroual Zoulikha[1]
[1]University Hospital, Nefissa Hamoud, Paediatric Unit, Medical University, Algiers, Algeria

Background
Hypophysitis is a rare inflammatory disease of the pituitary gland that can closely mimic neoplastic tumors such as histiocytosis or germinoma. In pediatric patients, it's challenging to distinguish between these conditions because of their overlapping clinical, endocrinological, and radiological features.
Case Presentation
We report the case of a 5-year-old child who initially presented with polyuria, and polydipsia. A hormonal evaluation confirmed central diabetes insipidus, and the patient was started on desmopressin therapy. Brain magnetic resonance imaging (MRI) revealed an enlarged of pituitary gland and thickened stalk, Tumor markers commonly associated with germinoma, including beta-human chorionic gonadotropin (β-hCG) and alpha-fetoprotein (AFP), were negative. Autoimmune evaluation was negative. The patient was started on oral steroid therapy at a dose of 1 mg/kg per day for one month. The initial response was significant, with regression of pituitary stalk thickening on follow-up MRI. However, new anterior pituitary deficiencies (GH, TSH, and ACTH deficiencies) developed. A Follow-up MRIs showed a progressive disappearance of pituitary stalk thickening, while the pituitary gland became hypoplastic. Considering the persistent endocrine abnormalities and the possibility of an underlying neoplastic process, Regular clinical monitoring was maintained through serial imaging and endocrine evaluations.
Conclusion
Autoimmune (lymphocytic) hypophysitis is a rare disease that should be considered in the differential diagnosis of any nonsecreting pituitary mass. An accurate diagnosis is crucial in guiding appropriate treatment and preventing long-term complications.

A complex case of growth hormone deficiency and pituitary mass in an adolescent girl

Dalar Tumasyan[1], Hasmik Khachatryan[2,3] & Renata Markosyan[1,3]

[1]Wigmore Women's & Children's Hospital, Endocrinology Department, Yerevan, Armenia; [2]Muratsan University Hospital Complex, Endocrinology Department, Yerevan, Armenia; [3]Yerevan State Medical University, Endocrinology Department, Yerevan, Armenia

Introduction
Growth hormone (GH) deficiency and pituitary stalk diseases are rare but significant conditions in pediatric endocrinology. However, distinguishing between infundibulohypophysitis and germinoma is crucial, as their management differs significantly—infundibulohypophysitis requires glucocorticoid pulse therapy, whereas germinoma necessitates alternative oncological treatment. In this case, a biopsy is necessary to determine the nature of the lesion.
Objective
This case highlights the importance of accurate differential diagnosis and a multidisciplinary approach in managing patients with GH deficiency.
Case
A 13-year-old girl was referred to the endocrinology department for evaluation of growth retardation, polydipsia, and polyuria, first noted at age 9. During examination height SDS was -3.43, BMI SDS was -2.49, and the bone age was 9–10 years. Karyotyping confirmed a 46XX genotype. Initial evaluations raised a suspicion of diabetes insipidus. Brain magnetic resonance imaging suspected lymphocytic infundibulohypophysitis. Laboratory investigations showed slightly elevated prolactin levels: 39.45 ng/ml (N <23.3 ng/ml), reduced IGF-1: 73.6ng/ml (IGF-1 SDS= -3). Other autoimmune diseases, including celiac disease, were ruled out. A comprehensive immunological panel yielded no abnormalities. Neuroendocrinological assessments included alpha-fetoprotein and beta-human chorionic gonadotropin (β-hCG), both of which were normal. Considering the possible autoimmune nature of the underlying disease, the IgG4 level was assessed and found to be normal. Growth hormone (GH) deficiency was confirmed following two stimulation tests. The arginine stimulation test revealed a peak GH level of 1.57 ng/ml, while the insulin test showed a maximum GH level of 1.03 ng/ml, both below the normal range. Cortisol levels were within normal limits during the initial testing; however, during hypoglycemia, cortisol did not appropriately increase, leading to a diagnosis of subclinical hypocorticism. With water deprivation test urine specific gravity was 1015, which ruled out diabetes insipidus. But one month later she was readmitted with persistent polyuria, polydipsia, and weight loss. To address these symptoms, desmopressin treatment was initiated to evaluate its effectiveness. A lumbar puncture was also performed, AFP and HCG were determined in the lumbar exudate to rule out germinoma, and no abnormalities were found. She started treatment with GH. A follow-up MRI is planned three months later to evaluate the size of the suspected mass.
Conclusions
This case underscores the importance of a thorough and systematic approach in the diagnosis of growth retardation and suspected hypopituitarism. As we were unable to perform a biopsy, a repeat MRI is necessary to further evaluate the pituitary mass.

TSH-secreting pituitary macroadenoma: a case report and therapeutic considerations

Grigoris Effraimidis[1], Nektarios Adamopoulos[2], Stefanos Tamouridis[2], Maria Galani[2], Athanasios Kasotas[2], Eleni Georgiou[2], Ioannis Gkountios[2], Anastasia-Konstantina Sakali[2] & Alexandra Bargiota[1]
[1]Faculty of Medicine, School of Health Sciences, University of Thessaly, Department of Endocrinology and Metabolic Diseases, University General Hospital of Larissa, Larissa, Greece; [2]Department of Endocrinology and Metabolic Diseases, University General Hospital of Larissa, Larissa, Greece

Background
TSHomas are rare pituitary tumors with an incidence of approximately 1 per million, accounting for 0.5% to 3% of pituitary adenomas. They present significant diagnostic and management challenges.
Case Presentation
A 51-year-old woman with a history of pulmonary embolism, hypertension and hypothyroidism on levothyroxine (LT4) with no regular follow-up, on her preoperative evaluation for an ovarian cyst removal had elevated TSH and free T4 (fT4) levels and was referred to our center for further evaluation. LT4 was discontinued and six weeks later the patient was clinically hyperthyroid with a TSH: 8.3 (0.27-4.20) mU/l,fT4: 5.3 (0.93-1.70) ng/dI, fT3: 11.2 (2.0-4.4) pg/mI. Her sex hormone-binding globulin was raised (SHBG >19 µg/mlæ upper normal limit 10.5) and the rest of her pituitary function was within normal range. Thyroid ultrasound revealed no goiter and there was no family history of thyroid disease. Due to technical and financial constraints, serum alpha subunit measurements were not performed. After assay interference was excluded, dynamic endocrine testing was conducted. The TSH response to TRH stimulation (200 µg TRH intravenously, with TSH measured at baseline, 20, 30, and 60 minutes) was blunted: baseline TSH 12.9 mU/l,peak TSH 17.9 mU/lan increase of 1.4-fold. A T3 suppression test (100 µg of liothyronine daily divided into four doses over 10 days; 25 µgX4) showed no suppression of TSH (TSH 8.4 mU/lafter T3-test.) SHBG levels remained elevated. The findings of these tests were indicative of a TSHoma and therefore the patient had a pituitary MRI which revealed a 17 mm× 11 mm×10 mm suprasellar pituitary macroadenoma. A long-acting somatostatin analog therapy (octreotide LAR 20 mg every 28 days) was initiated and her TSH and fT4 levels dropped within the normal ranges (2.4 mU/land 1.3 pmol/lrespectively).
Conclusion
TSHomas typically present with elevated free thyroid hormone levels and inadequate TSH suppression or are incidentally discovered as sellar masses. The diagnostic approach involves biochemical evaluation (including SHBG, and serum alpha subunit), dynamic testing (TRH stimulation and T3 suppression tests), and often a short course of long-acting somatostatin analog therapy. Pituitary MRI typically reveals findings consistent with an adenoma. While transsphenoidal resection remains the treatment of choice, pharmacotherapy with long-acting somatostatin analog treatment may also be appropriate in selected cases. Factors such as patient preference, absence of chiasm compression, and cavernous sinus invasion (Knosp grade 3B-4) with a low likelihood of gross total resection influence the final decision for treatment.

Pituitary stalk interruption syndrome as a cause of central hypothyroidism, growth hormone deficiency and hypogonadotropic hypogonadism: a case report

Beata Sawicka[1], Hanna Borysewicz-Sańczyk[1] & Artur Bossowski[1]
[1]Department of Pediatrics, Endocrinology, Diabetology with Cardiology Division, Medical University of Bialystok, Bialystok, Poland

Background
Pituitary stalk interruption syndrome (PSIS) is a congenital disorder characterised by the triad of an absent or exceedingly thyn pituitary stalk, an ectopic or absent one of pituitary part. PSIS is a common cause of congenital hypopituitarism, and causes a growth hormone deficiency. PSIS features in later childhood may inculde: short stature and delayed puberty. The prevalence of PSIS is unknown. The diagnosis is confirmed through MRI. Treatment should commence as soon as a diagnosis is established to avoid complications, and consists of hormone replacement.
Case report
The 10- year- old boy was diagnosed with short stature. He was born from a normal pregnancy, delivery in 40hbd, in good general condition, weight 4800g, length 63cm. According to anthropometric data, from early childhood, height was below the 3rd percentile. Due to decreased fT4 levels with normal TSH levels, l-thyroxine was included in the therapy. When the patient became euthyroid, he was diagnosed with growth hormone deficiency. Magnetic resonance imaging visualized pituitary stalk interruption syndrome. Actually during therapy with recombinant growth hormone we observed increasing velocity of growth. At puberty, the boy was diagnosed with hypogonadotropic hypogonadism and started therapy with gonadotropins. Genetic testing excluded a mutation within the complex pituitary hormone deficiency genes.
Results
1. PSIS is a rare disease with various clinical characteristics. 2. Diagnosis of PSIS is often delayed, because signs and symptoms are often not evident during the neonatal period. 3. Early diagnosis of hypothyroidism, growth hormone deficiency, hypogonadtropic hypogonadism and appropriate treatment gives a chance for normal development of the child.

Autoimmunity in a patient with prolactinoma: coincidence or consequence?

Rukiye Sena Turk Yilmaz[1] & Jasmine Gujral[1]
[1]Yale School of Medicine, Pediatric Endocrinology, New Haven, United States

Objectives
Prolactinomas are pituitary adenomas that usually respond well to treatment with dopamine agonists with reduction in both prolactin levels and tumor size. Additionally, patients with autoimmune diseases, such as systemic lupus erythematosus (SLE), have been shown to have elevated prolactin levels. We describe an interesting patient with a prolactinoma who responded biochemically to dopamine agonists, but the tumor size remained resistant to treatment. The course was complicated by evolution of an autoimmune presentation questioning the cross talk between prolactin and autoimmunity.
Case Presentation
